BUILDING NEWS

AND

ENGINEERING JOURNAL.

VOLUME THE TWENTIETH.

JANUARY TO JUNE, 1871.

OFFICE FOR PUBLICATION AND ADVERTISEMENTS:

31, TAVISTOCK STREET, COVENT GARDEN, LONDON.

INDEX TO VOL. XX.

MACHINES: patent mitreing, 173; for planing wood, 222; tunnelling, 100
"Made Ground," 35
Madras irrigation works, 37
Magnitude, ideas of, 241
Mains for water, 185
Maintenance of highways, 119
Majolica painting, 131
Making roads, 379
Malady of modern art, the, 194
Malton, new bridge at, 116
Manchester: 443, 477, 560; Church of the Holy Name, 490
Mansion in Mark-lane, old, 462
Marble, treatment of, 44
Marbling and graining, 51, 69, 91, 113, 237

NATIONAL: Gallery, the, 234, 358, 495, 521; technical university, 501
Natural History Museum, Kensington, 374
Nature in ornamentation, 124
Negligence, Indian Public Works Department, 3, 24

OBITUARY:—Ainmiller, Max Emanuel, 5; Bennett, William, 272; Dean, William Henry, 305; Gaetano de Minicis, 462; Gertner, Professor, 375; Gliemann, Albert, 462; Grant, Henry, 311; Hardwick, Philip, 28; Hayter, Sir George, 76; Hess, Peter von, 311; Holt, H. F., 357; Jager, Gustav, 358; Minardi, Tommaso, 100; Munro, Alexander, 39; Palizzi, Francesco Paolo, 335; Poste, Beale, 311; Stanfield, James Field, 335; Van Schendal, Petrus, 21; Willement, M., 221

PAINTED decoration of Norfolk churches, 168, 289, 467

Parliamentary Notes:—Albert Memorial, 171, 331, 355; Chelsea Embankment, the, 355; communication between St. James's and Westminster, 250, 310; Crown lands and forests, 374; dismissal of Mr. Barry, 519; drinking-trough in Piccadilly, 497; East London Museum, 234, 460; effluvium in St. James's Park, 331; Epping Forest, 208, 354; Euston, St. Pancras, and Charing Cross Railway, 135; General Post Office, the, 508; Hamilton Gardens, 331, 460; hospitals at Stockwell, 394; house for the learned societies, 234; Houses of Parliament, the, 171; Hyde Park, 171, 250, 374, 498; Inclosure Law Amendment, 135; Indian Engineering College, 189, 234; inhabited house duty, the, 355; Kensington Gardens, 355; land tenure, 135; law of land settlement, 331; leaky railway bridges in London, 519; lines of railway in India, 250; Metropolitan Buildings and Management Bill, 394, 498; metropolitan water-supply, 135, 331, 417, 437; Museum of Patents, 135; National Gallery, the, 234; Natural History Museum, Kensington, 374, 519; New Courts of Justice, 135; New Forest the, 309, 331, 355, 417, 497; New Palace-yard, 497; new Post Office, the, 153; new public offices, the, 189; new route to India, 331; new schools, the, 331; new street from Charing-cross to Tottenham-court-road, 519; Palace of Westminster, the, 171, 519; Park-lane, 460; patents for inventions, 135; pollution of rivers, 331, 394; pottery in the International Exhibition, 437; public monuments, 519; public parks and museums, 135; Royal Sanitary Commission, 135, 331; statues of statesmen in Westminster, 460; street tramways, 355, 374, 394, 519; South Kensington Museum, 417, 519; Thames embankment, the, 417, 460, 497; Upper Trent Purification Bill, 374; various public works, 520; Wellington monument in St. Paul's, the, 208, 394, 417

THE BUILDING NEWS

AND ENGINEERING JOURNAL.

THE MONT CENIS TUNNEL.

THE world no longer builds Pyramids. We fear that it no longer builds cathedrals. But its genius is devoted to works not less marvellous and mighty. Time was, not long ago, when amazement was created by a tubular bridge, spanning an arm of the sea, beneath which the proudest line-of-battle ship could pass, all sails set. Then a great stimulus was given to human pride by the opening of the Suez Canal; yet now a work has been accomplished distancing all example. The Alps have been tunnelled through, and Italy has established a complete communication with the west of Europe. That is, a road has been hollowed through Mont Cenis, one of the most gigantic mountains in Europe—a road between seven and eight miles long, perfectly even, begun at both ends simultaneously, and finished in the centre with mathematical accuracy, and principally by water-power compressing air. A brief record of the Herculean labour may be interesting. It was commenced in 1857, when, by a trigonometrical survey, a tracing was obtained of the axis of the contemplated tunnel. This, in itself, was not an easy task. Every observation had to be taken at altitudes of from three to ten thousand feet above the level of the sea, amid incessant atmospheric fluctuations. An observatory was erected on the peak of Grand-Vallon, literally above the clouds, and the signals thence were transmitted to the two opposite valleys of Fourneaux and Bardonnéche. In these, around the poor hamlets which could scarcely gather in food sufficient for their own inhabitants, a new population, on a large scale, was planted, and we may conceive the difficulty of supplying it, far away as it was from towns or railways, with provisions, besides constructing canals, reservoirs, workshops, and engine-houses, and fitting up a stupendous complication of machinery. Water had to be brought through an artificial channel from a torrent more than a mile away. A gas manufactory had to be set going to light the men at their labour, and then the boring machines began their work, at which, unless when interrupted by political causes, they were employed, day and night, for twelve years, until last week, when the last fragment fell, and the artisans from France and the artisans from Italy, coming face to face, after mining towards each other so long in the bowels of the mountain, cheered again and again through the friendly gap. The tunnel was to be eleven feet wide, and eight feet high; a frame work, rolling on double-rails, and carrying ten perforators, was advanced incessantly close to the face of the rock; by hydraulic pressure these augers worked into the stone as a gimlet works into a plank, only that they receded after every blow, when a jet of water followed to clear the holes and cool the iron; when eighty of these perforations, about a yard in depth, had been made, workmen and apparatus were taken back two hundred yards, behind massive gates of beams, called safety doors; a fresh gang then loaded the mine and fired it; a third pumped in fresh air, to clear off the smoke and exhalations; finally, a fourth carried away, in trucks, the débris that had crumbled from the rock. At first, owing to the novelty of the operation, this process could only be carried out about once a day; the machinery was new to most of the men who worked it; there was risk in forcing the work; and thus about a yard in twenty-four hours was all that could be accomplished. Gradually, however, as the work became more familiar, its rate was accelerated, and twenty yards a week was the average. But it is not to be supposed that when the excavation, eight feet high by eleven wide, had been made, that the tunnel was complete. These dimensions would have been utterly inadequate to the object in view. Enlargement had to be made by the ordinary methods, and the surface hewn smooth by the axe into the conventional horse-shoe arch, afterwards lined with elaborate masonry. The pick went first, the mason followed, all three—the borers, the pick, and the mason, keeping apart at regular distances. Perhaps, however, the most interesting facts connected with the undertaking are those which bear on the special machinery employed, and particularly of the two systems for obtaining the requisite supply of fresh air. From this point, for a time, we follow somewhat closely the report of the Italian engineers. Their first idea was that of what is called a column compressor. It had been estimated that a tension of six atmospheres was required for the compressed air to become a power in the tunnel, and to produce this a fall of eighty-five feet was necessary. Accordingly, at Bardonnéche, the whileom unknown village, now grown into a town encircled by a camp, a reservoir of Cyclopean size was erected, nearly a hundred feet above the engine-house; ten compression-columns, siphon-shaped, were fitted to it, each communicating with a chamber full of natural atmospheric air, of such a height and size that the impetus of the water, when turned on, was just sufficient to carry it to the top. This was effected by opening a valve in the column, through which the water in the upper part rushed, driving before it the water at rest below the valve in the lower part of the siphon formed by the column. Rapidly rising above its original level at the bottom of the chamber, the invading water thus compressed the air contained in it, until the necessary tension was obtained, when the force thus created opened a valve at the top, through which every particle of the compressed air was expelled. The valve then closed, preventing any downward rush; the water was let off to be used again; another supply of atmospheric air was admitted, automically, so to speak, and so the work went on at the rate of about three pulsations a minute, a prodigious power being in constant course of production. Scientific opinion was, originally, very doubtful as to the success of this apparatus. The compressed air, it said, would burst any recipient that could be constructed for it; it would, at all events, ooze through the thickest plates of iron; it could not be carried a long distance through any pipes that could be manufactured. But soon the experiment vindicated itself. Lighted tapers were passed close along the tubes, and their flames were never stirred. Mechanically, the engineers of the tunnel were triumphant. Then arose the question—could workmen live in that deep hollow, with eight thousand feet of mountain piled above them, and no possibility of providing ventilating shafts? But the compressed air did double duty. Besides driving the perforators, a portion of it being allowed to escape created an atmosphere as free as that of the hill-side, flowing in a constant stream, and, moreover, keeping the excavation cool, in spite of the vast number of lights unavoidably in use. The compressed, indeed, was found to be much cooler than the atmospheric air. Such was the system at one end of the tunnel. At the other, hydraulic wheels and pump-compressors were employed, though the machinery directed against the rock was the same. In fact, by water was Mont Cenis hollowed right through its giant base; by water was every ton of necessities brought up to the scene of operation from the deep valley below; by water was the vitiated air sucked out of the tunnel, even when it had been driven close to the centre of the mountain. In the result, all the prophets of evil were disappointed; the machinery worked perfectly to the last, not a puff of steam was ever used, and the cost per dynamic horse-power was incomparably lower than that of the agency hitherto deemed indispensable. Well, the engineers have completed their task; the scientific class has learned a fresh and important lesson. What other results may be in prospect it is, as yet, impossible to tell. When the undertaking was begun, the whole region to be traversed by the line belonged to Italy. After the battle of Solferino, however, France advanced her frontier to the crest of the Alps, and took an immediate interest in the gigantic work, which became the subject of a special treaty. She would gladly, indeed, have had a hand in its execution; but to this the Italian Government would not consent. It had planned the tunnel, guaranteed its cost, and incurred the risk of failure, and it insisted upon retaining its control, and making of it an exclusively Italian trophy. But the French, after its completion, are to buy one half, at the rate of £120 per yard. It will easily be imagined with what anxiety the engineers must have watched the approach of their labour to an end. Even among them prevailed a tinge of the superstition which largely infected the population of workmen engaged. When near to the heart of the mountain, would not some insuperable and mysterious obstacle arise, defeating their aim for ever? Again, had their observations been so perfect, had they dialled their path so accurately, that the two hollows would ultimately break into one, in a straight line, or might they not pass one another in that world of rock? Intense, therefore, was the excitement, and equal the joy when, from the French side, the miners heard, from the Italian side, the sounds of blasting, and the steady blows of the perforators as they struck, with irresistible force, into the narrow wall that alone remained between them now. And still more thrilling the moment when light answered light through

the shattered screen, and France and Italy shook hands in the middle of Mont Cenis, eight thousand feet below its summit. The work thus brought to a happy close, with singularly few accidents, and no delays except those caused by political events, is the longest in the world, besides being remarkable for the marvellous accuracy of the borings from two opposite ends to a central junction. It is in length thirteen thousand yards. Its height, as increased, after the machine-drilling, by ordinary implements and manual labour, is within three inches of 20ft., allowing for the passage of any load that could possibly be dispatched. The width is slightly more than 26ft., permitting the laying of a double line, with the usual "six foot" between. It was anticipated that the excavation of this vast hollow would bring to light some novelties of geological science; but the result, so far, has been disappointing. Two-thirds of the distance cut through were composed of schist; then came an immense belt of limestone, to the infinite delight of the workmen, whose energies went apace while this comparatively soft material was being operated upon; but afterwards, their patience was sorely taxed, though their intrepidity never failed, by a solid heart of quartz, which broke the tools, required double blasts, and was broken through, not yard by yard, but inch by inch, so that twenty-four hours of unremitting exertions often showed an advance of only two or three feet, though a pressure of ninety-six pounds to the square inch had been almost incessantly applied. And now that the doubts naturally created by an enterprise so stupendous are solved by its success, we may ask what are the benefits to be expected from a triumph against the probability of which, not many years ago, would have been quoted the ancient, discouraging, ignorant saying, *opposuit natura?* Nature opposes nothing, which men undertake with heart, and hope, and knowledge. It is the old story of Dr. Lardner offering to eat the first steamer that crossed the Atlantic. It is again the still older story of "natural boundaries," of which the Isthmus of Suez was formerly one and the Pyrenean range another, while the Alps could never be traversed unless by a Napoleon on a mule, leaving a Moscow of human ruin in his wake. Within a very little time, the tourist may demand his railway ticket, not over, but through the Alps, penetrated for him, and converted into a road by the united action of air and water only. This, then, will open Italy to the commerce, and especially the Indian traffic, of Europe, so long shut out from her, throwing two tides upon Genoa and upon Brindisi, and promising to revive the prosperity even of Venice. The tunnel has been a costly construction, yet no prediction could be more safe than that it will repay its charge a thousand upon a thousand fold. And it has this speciality, it must last as long as the earth. No other monument of man's labour can be compared with it for durability. Great pyramids, temples, columns, aqueducts, cathedrals, fortresses, and the various high-reared structures adorning the earth, from the Towers of the Cyclops to the Chinese Wall, must moulder to their foundations in the process of ages; but even time cannot destroy an excavation. It may be choked, its roof may partially fall through, its artificial lining of masonry may be warped from the rock, and encumber a neglected and forgotten railway—a result not impossible in the event of a protracted and absorbing European war; but the tunnel must remain, even though it should be left for centuries disused, and be discovered in some remote period, and wrangled over by pedants as an antiquity. However, even supposing it of less importance than it actually is—an importance scarcely to be over-estimated—the lesson in mechanics which it has taught has written many a new and instructive page in the Book of Science. Of course, conditions existed in this case—the altitude and abundance of the water sources especially—which would not be found everywhere; still a great principle of dynamics has been, if not actually evolved from the project of the Italian engineers, at any rate freshly-adapted, and armed with powers never before dreamed of. The air and water which, without cost of fuel, drove the Mont Cenis perforators, would drive any stationary machinery existing. The Americans have invented for similar borings an apparatus in which jets of fire are employed against the rock; but their apparatus, so far as its details are before us, appears excessively complicated, which is not a usual characteristic of American machinery. But, although the tunnel is practically complete, in so far as that its advanced headings have been driven to the centre of the mountain, the necessary enlargement has been carried only a part of the way, while the inner crust of stonework covers as yet only partial sections at either end. This work, however, is so easy that the progress of a day even is fairly distinguishable. The smoothness of the floor, so to term it, will, after this comparatively simple task has been finished, render the laying of the permanent way an ordinary matter of contract, so that within a few weeks at the latest the line through Mont Cenis would be available, were it not that difficulties apart from the prodigy wrought by the Italian engineers will yet remain. Northward of the tunnel, a branch is being constructed to connect it with the Paris and Lyons Railway, with a large number of formidable physical obstacles to overcome—viaducts, bridges, and perforations of the iron-like quartz so abundant in that region. Need it be said that the pick lies idle on the ground, and that all the gunpowder exploded is used for purposes other than those of blasting? The navigators are in uniform, bearing rifles shoulder to shoulder with those who employed them. The clerks of the works are pelting the Prussians with bullets from behind the thick forest trees of the Franche-Compté. Thus the war impedes, upon this path also, the labours of peace. Otherwise a very brief time would elapse before a train starting from Calais would proceed on an unbroken gauge to Brindisi, a distance of 1,390 miles. At the Italian end, too, some colossal works have to be accomplished, and though there are none except natural impediments in the way of the engineers, no success gained by them can bring about the grand practical result desired until the French and the Germans have buried the hatchet between them. The Chevalier Maus, therefore—whom history will credit with the original conception of the Mont Cenis tunnel, while the Signori Sommeiller and Grattoni must ever be remembered for its execution under their designs, and the inspiration of their courage—may have to wait several months before the crown is put upon his matchless project. As it is, however, his estimates as to expense and time have been borne out to an astonishing degree, since, of course, he was not responsible for interruptions due to political causes. He said the excavation might be pushed on at the rate of a mile and a half a year. This calculation was almost precisely justified, taking one actual working period with another. The valley of the Arc was joined to Bardonnèche at the rate of a mile and a half per twelvemonth. This, in itself, may be a source of legitimate pride to that generation of Italians who, for the first time in centuries, have shown themselves emulous of the ancient Roman daring and the ancient Roman genius. Moreover, the fact that his theoretical delineations, absolutely copied after the practical surveys of the engineers, brought the duplicate tunnels to a meeting exactly where it was intended, is rendered more noteworthy by the circumstance that the tunnel, although, as we have said, perfectly even and smooth, is not upon a plane, the difference of level between the two termini amounting to no less than 435ft., the slopes running up from the openings and terminating in the centre. At Fourneaux the height above the sea at which operations commenced was only 3,964ft., whereas the first stroke of the Italian pickaxe on the southern side of Mont Cenis, or Mont Frejus, as that section of the range is sometimes called, was at an altitude of 4,381ft. The two gradients however, were totally different one from another. That from Bardonnèche has a rise of 1 in 2,000, that from Fourneaux a rise of 1 in 45, the latter suggesting no slight difficulties in the way of traffic, and the more so since a continuous drip is expected, and has, indeed, been provided for by gulleys in the lining of masonry. The rails, consequently, will be wet and slippery, so that, now the problem of the tunnel itself has been solved, another will arise—how and with what engines to work a line which may be expected to carry an enormous traffic? The Italian engineers, then, are not yet entitled to rest beneath their laurels. Having made the road, they must show how it can be used. Had they possessed the information—impossible for them to possess until after the event—which experience has brought forth, they would have worked probably more closely towards a level, but it was feared that a deluge might burst from the bowels of the mountain and swamp the labourers at their work unless provisions were made for rapidly running off the water. No such catastrophe occurred, and this monument of the modern Cyclops is not stained with the blood of a single human being.

SHAM EAVES-CORNICES OR REAL PARAPETS?

OUR city architecture—our warehouses, and offices, and shops—is mainly an architecture with parapets. In the great bulk of it, the roof does not overhang the walls; it finishes inside them, and they are carried up several feet above the gutters as a protection against accident or fire. The question is, how to treat these parapet walls? They evidently form the true finish of the building next the sky: is it possible to make them a beautiful and effective finish to it? After walking through mile after mile of London streets one might think that this question suggested an absurdity. All that human ability can do with a parapet, one might conclude, is to lay a strip of York stone on the top of it, and stick a dummy eaves-cornice against its face. This is the modern decoration of parapets. This is what all the talk about true principles of art—about the necessity for ornament to spring out of actual construction—comes to in average practice. The actual construction is a parapet, and the ornament we select for it is an eaves-cornice. Principles of art, like many other principles, do indeed sit very lightly on some of those who profess them; for it is not only the rigid Classic school, who make a religion of not thinking for themselves, whom we may thank for the absurdity in question. If the practice were confined to them it would be a pity to waste our readers' time in considering it. A rigid Classic man, to all appearance, will soon be as great a curiosity as a dodo. It is wasting force to fight against a fast-vanishing race; but, before they quite disappear, it might be both useful and interesting to preserve a record of their singular habits. Their great peculiarity is, of course, the designing of all buildings by a kind of uniform recipe like the following:—"How to make an architectural design for a church, theatre, picture-gallery, prison, palace, workhouse, tabernacle, public office, public-house, west-end terrace, model lodging-house, or row of cottages. Set out an oblong block large enough to contain all the rooms that are wanted. Divide the front of this block into as many horizontal strips as there are stories in height. Put a row of dots along each strip, at equal distances, as if you were dibbling for cabbages, and plant a window at each dot; or, at opposite points, on the ground story, a door instead. This forms the 'stock'—the basis of all design; but you may season it according to taste and means. If you have

but a little money to spare, put an architrave round each window; if you can afford more, put a pediment over each as well; if you are regardless of expense, and wish to be magnificent, put a pilaster between each pair of windows, and a portico in front of the whole. Finish the front, whatever it is, with a cornice at top; and get the details of cornice, pilasters, pediments, and architraves, from Sir William Chambers or some similar authority." It is mere cruelty, as any one can see, to tell a follower of this school that a buiding with a parapet ought to differ from a building without. You are depriving him of his formula—the plank which saves him from drowning in a sea of difficulties. You are wanting him to think for himself, when his whole system is arranged to save the need of thinking. You are asking him to begin altering the crazy old dwelling that shelters him, when he knows that if he once begins he can never leave off; the whole affair is so rotten that it will fall about his ears if he touches a stone of it, and the part you take exception to is really no worse than the rest. There is little use in quarrelling with one detail where the rest are as bad: you have only to wait, and they will all come down together. Let the orthodox Italian clique have as many sham cornices as they like—the more the better. It is to a different quarter that these remarks are directed—to the authors of our Neo-Classic semi-Gothic designs. We do not address the real Gothic architects of the day, because they do not commit the absurdity in question; nor the rigid Classic ones, because they cannot help committing it. But between these two extremes is a large and increasing class. It includes men with Gothic tastes, whose clients will not have Gothic; men who admire Mediæval work, and yet feel that it needs altering for modern purposes; men who want to put some life into the dry bones of Italian formulas; and men who are vainly trying to originate, by themselves, a new style altogether. Their work, of course, differs greatly. Very much of it shows a striking want of harmony between the different details employed; a contradiction in character, perhaps, between its main features and its minor ones, or a number of attempts at novelty with no unity of feeling to connect them. But in spite of these faults, much of it does at least display the real construction. With one almost universal exception it is more honest than the rigid Classic, if not more beautiful. The doors, the windows, the lintels, the arches, the piers, have at any rate no disguise; but there commendation must stop. Look at the top of the elevation and the principle is abandoned. The roof is hidden behind a parapet, and the parapet is disguised with an immense cornice. After thinking for himself to some extent in all the rest of the work, the designer falls back on the Classic man's recipe at last; he gives up the attempt to make his decoration spring out of his construction. He lets the parapet shift for itself, and be as ugly as it likes; all he can do is to put up a great piece of scenery in front of it.

The most obvious fault of this practice is, perhaps, the unreality of it. But it has others little less serious. Suppose that the heavy horizontal cornice were, what it is not, the natural finish of our street architecture. Even then, for an English city, it would be a most unfortunate finish, and one that it would be worth avoiding, even by a change of system. For what can look worse in a street view than a series of horizontal masses not ranging with each other, not following any order or design, but jumping up and down in purely accidental fashion? What can look worse, in short, than the perspective of a London street on the present plan? It matters nothing what the separate buildings may be; their joint effect is simply detestable. And the reason of this is that while they are all trying to look horizontal the main conditions of the case make each of them by itself a separate vertical strip. The horizontal system, indeed, may be carried out under stringent regulations with success. If people are ready to pay the price for it—the price in liberty and individual convenience—they may have streets like those of modern Paris. If they will submit to interference at every point; to having the height of their buildings, the levels of the cornices, the number and size of the different stories all settled for them by a law like those of the Medes and Persians, they may follow the horizontal principle to some purpose. They may then have uniformity and regularity, and all the rest of the Classic virtues, to their hearts' content. But none of these things can they possibly get while every man does what is right in his own eyes. If A is to build a warehouse six stories high, and B an adjoining one of five stories, there is no hope for street architecture on the horizontal type. But there is every hope of it on the opposite one. For while the first system can only live at all in an atmosphere of rules and regulations—of stiffness, and evenness, and regularity—the other asks above all things for life and freedom. Give it roughness and irregularity, and it makes it striking and picturesque. This is its own element. It will deal with our strips of house-front, and make them artistic by making them vertical. And to make them so, its first step will be to remove their absurd sham cornices. Other changes will come in the track. It will put gables here, steep roofs there, and domes in a third place—just as they may be practicable and useful. But first of all it will make every parapet appear a parapet, and every dummy cornice disappear altogether. It will show the roofs wherever it can, and show them through the perforations of the parapet, if they cannot be seen above it. It will give us a skyline not too hideous to look at; and it will admit light instead of casting shadows into our narrow courts and passages. For the darkness which they produce is another fault, and a serious one, of our useless cornices. One might expect that where light is so precious as it is in a city street, the architect would make a main object of economising it. If he stretched a point either way, his temptation, it might seem, would be to omit the cornice when it was wanted. No one could think that he would be always putting cornices in when there was not the faintest excuse for them,—that in dealing with a narrow street he would wish to darken it still further by unnecessary projections. It is a strong instance of the force of habit that it should overpower considerations of use as well as of beauty. Light in a London office is worth money. To shut it out, is either directly to lower the rent, or at least to diminish the chances of letting. And yet such is the power of custom, that owners will submit patiently to have their property injured, if the injury does but come in a familiar and accustomed form. There is a fourth fault which might be noticed in connection with the subject, though the three previously referred to are enough for our purpose. This is the propensity which some of these sham cornices have to fall on people's heads. Inspired, perhaps, with more artistic feeling than their contrivers, they seem, at times, to feel themselves "de trop." They become conscious, as it were, of occupying an indefensible position, and lose no time in getting out of it. We have said it is sham cornices chiefly which do this; for to a real cornice, if properly constructed, it is hardly possible. The main stone of such a cornice is tied down by the weight of the roof, and cannot be overbalanced by any pressure that is likely to come upon it. It is very different when all that keeps it down is the weight of a thin parapet, in some cases only a foot or two in depth. Bad art and bad building generally go together, and the present case is no exception to the rule.

What we have said is not meant at all to bear upon the question, whether in the abstract parapets or overhanging eaves are best. In thin-walled buildings our own preference would be for the latter; guarded, perhaps, as at the S. Giles' Schools, by an iron railing attached to the gutter. But what we wish to insist on is this: if the parapet is adopted, let it be made the best of. Let its decoration spring out of its construction,—as it does in the thousands of Gothic parapets, which seem to exist in vain as far as the designers of our London warehouses are concerned. Let the parapet be made the ostensible, as it is the actual finish to the design; and let the eaves-cornice, whether Gothic or Classic in type, be confined to elevations which have eaves to require it. All that is wanted below a parapet is a moderate-sized string-course to act as a drip; and this will neither darken our streets nor endanger our lives.

NEGLIGENCE, INCAPACITY, AND CORRUPTION OF INDIAN PUBLIC WORKS DEPARTMENT OFFICIALS.

THE Indian Government deserves all praise for its prompt action in a case of loss of life, occasioned by the rascality of a contractor, which should have been discovered by the officials connected with the Public Works Department. We give a short account of the matter condensed from the *Bombay Gazette* :—

In June last one of the buildings in course of construction at the Gun Carriage Factory at Allahabad fell in, and a loss of several lives was caused by the accident. The Government took the matter up, and appointed a committee to investigate the causes of the accident, and to report on the responsibility of the several officers of the P.W.D. contractors, or others, connected with the design or construction of the building. The report showed that the failure of the centre wall was the cause of the accident, and that the mortar used was of the most inferior description. The bad quality of the mortar, besides, was not confined to the one building, but was observable in all the other buildings of the factory, including sheds for machinery to be driven by steam power and a chimney shaft 123½ft. high. An analysis showed that the mortar contained only 6 per cent. of lime. The Government proceeds in its resolution to inquire in what degree the responsibility rests on each of the individuals concerned in the execution of the work. Beginning with the supervisor, one Bartram by name, Government decides that he has proved himself utterly unfit for the place he holds, and directs that he should be removed from the Public Works Department. With regard to Major W. Jackson, of the Bengal Staff Corps, who was the Executive engineer under whom the whole of the work which fell, and also the majority of the other buildings in which bad mortar was used, were carried out, the Lieutenant-Governor of the North-Western Provinces stated that he was wanting in the qualites essential to a successful service in the Department of Public Works, particularly in energy and power of control, and that he trusted too much to his subordinates. It was therefore considered impossible to arrive at any conclusion but that this officer should be removed from the Public Works Department. The Superintending Engineers in charge of the circle while the various buildings for the factory were in progress were—Lieutenant-Colonel C. D. Newmarch, R.E. (since dead), Major F. H. Cobbe, R.A.; Lieutenant-Colonel H. Rose, S.C.; and Lieutenant-Colonel F. Alexander, S.C. With regard to Major Cobbe, it is decided that it is not desirable to retain him in the Department of Public Works. With regard to Colonel Rose, the resolution says, "His Excellency in Council would have had doubts whether an officer who has shown such remissness as is apparent in this case ought to be allowed to remain in the Public Works Department, but in consequence of Colonel Rose's long service would have been content with depriving him of his position as superintending engineer, had he given no other cause for dissatisfaction. Two other serious instances of failure in duty, while he was an executive engineer at Rawulpindee, have, however, been very lately brought to the notice of the Government of India, which, taken in connection with the present case, have led his Excellency in Council to the conclusion that it would not be right to retain this officer in the department." Colonel Alexander has, in consequence of his proceedings in this case, been placed in a grade lower than that in which he would otherwise have appeared. Colonel Hodgson, who held the combined offices of Chief Engineer and Secretary to the Government of the North-Western Provinces, in the Public Works Department, during the whole of the period under review, comes in for a share of the blame. It is considered that "had he made such inspections of these particular works as might fairly have been expected of him, the bad quality of the mortar that was being used could not have escaped his notice." He is also held "mainly responsible that officers who evidently were physically unfit for the proper discharge of their duties should have been allowed to retain their charges. This occurred with reference to both Colonel Newmarch and Major Cobbe.

The lime contractor is to be criminally prosecuted, and the Governor-General concludes his order by a most severe and well-deserved reprimand to all concerned.

At a meeting of the Birmingham Town Council, on Monday, it was resolved to hire a steam street roller for six months, and also to procure a return of the expense of various kinds of paving for one of the streets of the town.

ARCHITECTURAL DRAWINGS.*

THIS work, which Mr. Burges has dedicated to the memory of Robert John, Baron Carington, consists of 75 plates of drawings, mostly of architectural details, with a few that may be more properly termed artistic, as relating to costumes, personal ornaments, &c. It has been published by subscription, and the subscribers, for whose interests the author has been almost too scrupulous (at least, such we anticipate will be the future verdict of the public), are, we think, to be congratulated upon the acquisition of their volume, though some of them have waited a considerable time for it.

In his introduction, Mr. Burges assures them that it will be found to contain exactly what was promised in the prospectus, viz., fac-similes of certain drawings, made at various times for his own instruction, with a short description of each subject; and as the letter-press of such a work as this is very seldom read, the description has been confined to the reasons that induced him to make the drawing and the various points of interest in the subject; and further on he says, in conclusion, he trusts he may honestly claim to have fulfilled the conditions of the original prospectus, "to deface the stones as soon as the plates have been struck off, and, above all, to allow no copies to go into the trade."

While giving the author full credit for his honesty and consideration for his subscribers, we cannot but feel some regret that these conditions, which would not have been imposed by any one but himself, were ever made. If a couple of hundred gentlemen have been the gainers, the public will certainly be losers by the arrangement, and many a rising young architect, who has not had the opportunity of enrolling his name in the fortunate list, will, hereafter, bemoan his sad fate, for the book, though by no means attractive, is eminently a useful one.

Its history, according to the author, is as follows:—"Some twenty years ago, when a pupil, I was taught that the proper way to study was to draw rough perspectives in a little sketch-book, accompanying these rough perspectives with small drawings of the details and a few measurements. The great object in a month's excursion was to fill the sketch-book, and then on our return to town the perspectives were to be drawn out more carefully in pencil upon yellow tinted paper, with an occasional shadow in Indian ink. It is needless to say that this latter process of drawing out rough sketches, left very much to be desired as to accuracy of proportion, to say nothing of detail and construction. After my pupilage, I went abroad for several autumns, with some of my friends, who made exceedingly pleasing sketches upon the spot, but unfortunately these were only one degree better than those produced under the former process, for each of us tried how many more sketches he could make in a day than his companion. On our return home these sketches were cleaned up, had their margins cut, were then sorted, pasted carefully into nicely bound scrap-books, and reserved, as a very cynical friend used to observe, 'for the inspection of parents, friends, and idiots.' I am ashamed to say how many scrap-books I filled with the sketches made during a few autumns, and at this point, under ordinary circumstances, I should have stopped. I had passed my pupilage, I had taken my foreign travel, and I should have gone into practice with these sketches as my stock-in-trade. Luckily for me, my cynical friend did not cease to ask why I drew this sketch?—of what practical good was this detail?—why had I not drawn the full-size curves of some particular moulding?—and, in fact, he asked me so many questions, and such embarrassing ones to answer, that I was at last obliged to confess that the sketches had been drawn for the vanity of making pretty pictures, and that they were useless, or nearly so, for the information they contained, and that the true destination of all such sketches should rather have been the waste-paper basket than the scrap-book."

We have quoted this confession at length, in order that the architectural students of the present day, whose names are not on the subscribers' list, may have the benefit of it, for the practice referred to has by no means yet been abandoned, nor are its pernicious effects so generally known and acknowledged as they should be. Were it otherwise, the value of the work under review would be less than it is. Still, we are aware that a better state of things does now exist, a fact, however, due in a great measure to the influence of Mr. Burges, who has for years been preaching by example as well as precept to his juniors upon this very subject. The members of the Institute of Architects have in their "Transactions" (Nov. 19, 1860) a valuable paper by him upon architectural drawings, in which the above experience and his matured views are clearly set forth, and the Architectural Association are showing by their "Sketch-book" how they have taken to heart the aforesaid advice. Subsequently the author had an opportunity of visiting Italy and France, and, as he says, he forthwith made up his mind to turn over a new leaf, and to measure, and as it were dissect, the architecture, and particularly that of the best work of the thirteenth century in the latter country. How much of this determination is due to the remarks of the cynical friend, we may gather from the continuation of this autobiographical sketch of the author, who set himself, as he describes it, to write a sort of grammar of thirteenth-century architecture, and to illustrate it with carefully-measured details, without wasting time by trying to make finished drawings, by means of the surroundings of the objects specially in view.

Although, unfortunately, this scheme fell through, partly from its being forestalled by that of M. Viollet le Duc's Dictionary, the advertisement of which then appeared, he continued the drawings for his own instruction, without any intention of publication.

The result of this tour, "a heap of rough cartridge paper of different sizes, blotted with ink, stained by rain, sometimes lined with pencil, sometimes with indelible brown, and often with common ink," Mr. Burges says he found to be to himself very valuable, for they taught him "the why and the wherefore which is the base of all architectural knowledge."

The determination of the author to give to others the benefit of what he had found so useful to himself, was one for which his subscribers cannot be too grateful, seeing that the personal advantage to himself likely to accrue by so doing was necessarily very small. We, however, venture to think that it will prove larger than his modesty has at all allowed him to calculate upon.

The preparation of the drawings for publication, and transferring them to stone, has been the labour, and we doubt not a labour of love, of Mr. Swindon Barber, Mr. Saunders, Mr. Tarver, and Mr. Lonsdale, and we are glad to learn that a very interesting section of it, that relating to costume, is likely to be continued by the two last of the above-named gentlemen, and republished in a separate form with additions.

To quote once more from the author's introduction, one of the conditions of the original prospectus, which he declares to have been scrupulously fulfilled, was the following:—"To insert no detail or stone joint that has not been drawn on the spot." Herein lies the keynote and special value of the volume whose contents we are about to describe, but of which our space will not on the present occasion permit us to say as much as we could wish.

To Beauvais Cathedral and the details of its construction the first eight plates are devoted, the choir being, in the opinion of the author, the most beautiful of all the beautiful buildings for which we have to thank the architects of the thirteenth century—owing its excellence to its designer having tried to improve upon the work at Amiens, which had been begun a few years before, and partly to the accident which rendered necessary the supplemental columns between the great arches.

We confess to some surprise at this statement, and the more so from its enunciation by the author, whose conception of beauty, as we presume to be set forth in his own works, we should have thought so different. Beauvais has but little of the massive and sturdy proportions of which he is so fond, and appears to us to show French Gothic already far declined from its highest point towards perfection that it once attained.

"One of the defects of the choirs of the great cathedrals of the Middle Ages is the disproportion between the side arches and those of the apse, and in the original design of Beauvais the defect was even aggravated, inasmuch as the side arches were only three in number, and therefore unusually wide."

Now the method in which a fundamental error of construction was remedied in this instance, not only without detriment, but even with advantage to the design, was, as no doubt most of our readers know, most remarkable; but it seems incredible that such a patched-up bungle, however admirable the patching, should surpass every other effort of the matchless architects of the Middle Ages.

Nor in our opinion does it do so, and we are inclined to think that Mr. Burges views with too great favour, this "white-headed boy" of his, to the illustration of which he has devoted so much time and labour, and which occupies the largest space appropriated to any single building in his volume. Not that we grudge one plate given to this subject, but we cannot endorse the above, as we think, too flattering testimonial to its merits; and when we hear of the difficulties which had to be surmounted, and some of which were not able to be surmounted during the process of its measurement, by reason of the "various iron bars by means of which the edifice is now kept together," notwithstanding the clever patching alluded to, we think it too evident that "something was wrong about it," and that that something is written in the comparative weediness of its proportions and the flimsiness, of which we would single out, as examples, the lanky scaffolding-like flying buttresses shown in plate 6, and the secondary arcade of the triforium in plate 7. Mr. Burges describes the tower, which likewise came to grief, as it fell in 1573, as a wonderful conception, of which records more or less correct are still extant, and we mention it in passing, as we could wish that some reproductions of the drawings of it "in several collections in Beauvais" could be more generally accessible.

The choir and its details are, in the work before us, tolerably fully given. They illustrate a section through the side of one of the apsidal chapels (plate 5). The lower parts of the building are the more carefully illustrated because the more attainable, but the heights of the inaccessible portions were procured by dropping tapes over the iron bars alluded to. Mr. Burges regrets that he did not draw these bars themselves, as though he regarded them as modern expedients, it is just as probable that many of them may be as old as the restoration of 1284, and therefore not as useless as well as unsightly as those with which Sir Christopher Wren has marked Westminster Abbey.

In the author's remarks on plate 1 (plan of this apsidal chapel), attention is called to the moulds of the mullions and arches of the windows being of exactly the same section,—"not a very desirable precedent to follow." A reference to the elevations of the windows, plates 7 and 8, will show at once that this defect is one of those marking the decadence of the style to which we have above referred.

We must now take leave of this valuable work, although we must again refer to it, as we have only just dipped into its con-

* "Architectural Drawings." By W. Burges, Architect. London: Printed by William Clowes & Sons, Stamford-street and Charing Cross, 1870.

tents, the variety in the character of which is only equalled by their scrupulous accuracy, and the intelligence with which the secrets of the construction of the masterpieces of the mediæval age have been investigated and explained by the author.

MAX EMANUEL AINMILLER.

WE have sustained a severe loss in the death of Max Emanuel Ainmiller, one of our art veterans, who breathed his last here on the 8th inst. Born in the year 1807, he devoted himself to architecture on his entrance into the Munich Academy. Here, however, he showed a special talent for ornamentation, and devoted himself to this branch of art. On completing his studies he received an appointment as ornamental designer in the Royal Porcelain Manufactory at Nymphenberg, but quitted this to join Frank in glass painting, for which he had long felt a decided inclination. He applied himself specially to the technical branch of this art, and we do not assert too much in saying that it owes to his unfailing exertions that distinguished position amongst the sister arts which it now holds. In former years he also drew the greater portion of the ornaments in the large windows produced by the celebrated manufactory at Munich, and justly shared the European fame that establishment then enjoyed and sustains at the present day. Under his direction were produced the splendid glass-paintings for the Cathedrals at Ratisbon, Cologne, and Speyer, for the churches of Au (a suburb of Munich), the University church at Cambridge, and latterly for S. Paul's Cathedral, in London, the Cathedral in Glasgow, and some public buildings at Edinburgh. His former studies in architecture subsequently led him to architectural drawing, in which he was distinguished both for the beauty and correctness of his designs, principally in the Gothic style. Ainmiller has contributed much to the splendour of the new Pinakothek. The Academy of Munich recognised the merits of their former pupil by admitting him as a member of their body, and he was honoured with several orders.

Munich, Dec. 18, 1870.

AZTEC DISCOVERIES IN MEXICO.

ADVICES in a Texan paper from Santa Fé state that Governor Arny, the special Indian agent for that territory, has found the Canon de Chelly, which was explored for twenty miles. The party found canons whose walls tower perpendicularly to an altitude of from 1,000 to 2,000ft., the rock strata being as perfect as if laid by the skilled hands of masons, and entirely symmetrical. Among these ruins of ancient Aztec cities many of them bear the evidences of having been populous to the extent of many thousands of inhabitants. In one of these canons—the rocky walls of which rose not less than 2,000ft. from the base, and whose summits on either hand inclined to each other, forming part of an arch—there were found high up, hewn out of the rocks, the ruins of Aztec towns of great extent, now tenantless, desolate. In one of those rocky eyries there remained in a state of good preservation a house of stone, about 20ft. square, containing one bare and gloomy room, and a single human skeleton. In the centre of the room were the evidences that fire at some time had been used. The only solution of this enigma thus far ventured is that these solitary rooms were the altar-places of the Aztec fires; that from some cause the people at a remote period were constrained to abandon their homes, but left one faithful sentinel in each instance to keep alive the flame that, according to the Indian traditions of these regions, was to light the way of Montezuma again to his people—their hoped-for Messiah and their eternal King. A close examination of many of the ruins proved that the builders must have been skilled in the manufacture and use of edged tools, masonry, and other mechanical arts. But who these people were, whence they came, and whither they are gone, is now probably one of the mysteries to remain eternally unsolved. Some of the ruins are reported to be stone buildings seven and eight stories in height—being reached by ladders planted against the walls. Round houses, 20ft. in diameter, built in the most substantial manner of cut stone, and plastered inside, were also found in excellent preservation. Astonishing discoveries have been made of gold and silver regions richer than any yet known on this continent. They are supposed by well-informed persons to be the East mines, of which tradition has handed down the most marvellous tales, and the mines themselves discover unmistakable evidences of having been successfully worked ages ago.

A PLEASANT COUNTRY CHURCHYARD.

WE ought to be very thankful that light has been brought to bear on the disgraceful condition of a Devonshire churchyard, which might, for all that has been done to prevent it, have caused a virulent outbreak of some contagious disease, and that in one of the most convenient, spots for spreading it throughout the kingdom. Devonport—now really a part of Plymouth—is in the parish of Stoke Damerel, and the parish churchyard is the only burial-place provided for the inhabitants. With the rapid increase of the population of Devonport it became necessary to add five acres of ground to the churchyard. This was done, and Mr. Rawlinson, who was in 1853 appointed to inquire into the health of Devonport, reported that there was room for 9,000 interments more. Since then 12,000 have taken place. In all, we are told, "from first to last something like 80,000 corpses have been deposited in these five acres, which would give each grave seven occupants, nearly six out of the seven being deposited in the present century." An order made in 1862 for closing the older portion of the burying ground, and prohibiting interment in the other part within a foot of existing graves, appears to have been systematically and scandalously disregarded. Coffins have been wedged into the ground wherever it was found by probing the earth with an iron rod that there was room. Ends and sides of coffins, bones, and even entire skeletons, have been repeatedly seen when new interments were being made. The inspector before whom the investigation was made mildly suggested that the yard should be closed in twelve months' time! We do trust the inquiry will at least result in some punishment for those who have sanctioned the continuance of this utter disregard of all the sacred associations connected with the dead, and of all the reasonable precautions that should guard the health of the living.

SNOW IN THE STREETS.

A HEAVY fall of snow always finds us unprepared in London. We are not going to grumble. We ought to be thankful that in the main thoroughfares, after it had lain for a day or two, and, in fact, when the officials seemed convinced that the frost really meant lasting, and that it consequently would not remove itself, the snow was swept and shovelled into heaps, and finally disposed of. This is at any rate an advance on the "let-it-alone" system which prevailed during the last great fall of snow four years since, when Fleet-street and the Strand became successively a lengthened slide and a continuous quagmire. But we have even now a desire to see something done for the side streets and the suburban thoroughfares. We hardly see why the omnibus conductors should charge us an extra fare on account of the frost and snow, because the scavengers, and vestries, and local boards, and other sleepy officials, don't do their work. We find one crumb of comfort, as usual, in other people's misfortunes. It is at least consoling to know that the Americans, who look for heavy snowfalls in winter time, have similar cause for grumbling. And the richest joke of all is to find the *Scientific American* advising the New York authorities to adopt the "effective method of getting rid of ice and snow" in use in London. The New Yorkers are welcome to our "effective method," and to the "authorities" who *don't* put it into practice.

THE BRADFORD CORPORATION ABATTOIR.

ON Monday the Corporation Abattoir, adjacent to Leeds-road, was opened. The buildings have been erected from the designs of Messrs. Lockwood & Mawson. At the east end of the abattoir an open space of ground is set apart for the drovers and dealers, where the live animals are sold. Enclosed lairs comfortably shielded from the weather communicate by doors immediately with the slaughtering place, and as soon as an animal is killed and dressed it can be readily passed forward by means of easily-worked appliances, into the carcase market, where the dead meat is sold. The carcase market is enclosed by an iron palisading, and outside this is a covered roadway, where the carts will receive the dead meat for conveyance to the retail dealers. On the opposite side of the roadway are a range of offices for the wholesale butchers. The pig market and slaughtering place is apart from the other erections, at the easterly end of the abattoir, every convenience such as hot water for scalding purposes, &c., being provided. Light is obtained from the north, the floors are laid with bricks covered with asphalte, water is plentifully furnished, and hydraulic lifts will enable heavy beasts to be raised and passed bodily into the carcase market without any difficulty. The cost of the premises will be heavy, but Bradford now possesses one of the most complete abattoirs of any town in the kingdom.

BUILDERS' CONTRACTS.

THE Council of the Royal Institute have altered clauses 19 and 20 of the General Headings for contracts agreed to by them on the 1st of August last, and published by us 28th of October, 1870. The clauses now stand as follows:—

19. If Employer make default for days in payment of any moneys due to Contractor, or if works be delayed for months by proceedings of adjoining owners, Contractor to be at liberty to suspend works, and require payment for works executed, materials wrought up, and loss on goods or materials purchased for the works, and not to be bound to complete contract. *Contractor to be entitled to such interest, and at such rate, on payment unduly delayed, as the architect may certify, or in case of dispute, as the Referee may award.*

20. Arbitration Clause—With regard to quantity or value of extras and omissions, or variations on the Contract, and questions of delay, or the withholding of certificates, or the true intent and meaning of the drawings and specification as to cost; *or as to the construction of the Contract, or as to any other matter arising out of the Contract, except as to matters left to the sole direction of the architect, under clauses* 1, 9 *and* 10. The Arbitrator being an Architect and a Fellow of the Royal Institute of British Architects, agreed to by the parties, or appointed by the President (for the time being) of the Royal Institute of British Architects. The Arbitrator to award costs between Employer and Contractor.

L'ABBAYE AUX HOMMES, CAEN.

THE Church of S. Stephen, attached to this abbey, is said to have been founded by William, Duke of Normandy, soon after the conquest of England. The sketch shows the aisle and chapels round the apse, which were built about a century later; some antiquaries consider them to have been built under Simon de Trevières, between the years 1316 and 1349. Mr. Wood (in Pugin's "Normandy") says: "At first sight I should have pronounced it a work of the twelfth century; but on examination there are circumstances which excite a little suspicion. The crenated ornaments on the ribs of the groins, the number of small shafts round the piers of the chapels, the openings between the chapels, the disposition of the little shafts against the wall, the smallness of the capitals to the slender shafts about the principal piers, are none of them exactly what we should expect in a work of the eleventh, or even of the twelfth, still less is the whole together what they should expect of the fourteenth century. To found a true decision it would be necessary to know exactly the authority on which the latter date rests, and to examine the work itself with this especial view: a practised eye would certainly find further discrepancies if such a difference of time really exists."

H. G. W. D.

TEIGNMOUTH, DEVON.—On Saturday last, December 31, the Teignmouth Local Board met to decide on the "Coombe Vale" competition plans, six sets of which were sent in last August for competition, bearing respectively the mottoes of "Experience," "Comme il faut," "Via," "Try," "Devonia," and "P. G. J." The first premium (£20) was awarded to Mr. S. Templer, architect, Teignmouth, for set of plans with the motto "Via." The second prize (£10) was given to Mr. J. Chudleigh, architect, Newton, for his set of plans bearing the motto "Try."

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page* 482, *Vol.* XIX.)

PLATE 16.—CONSTRUCTION OF A WREATH FOR STAIRS, HAVING SIX WINDERS LANDING ON A LEVEL FLOOR.

FIG. 1 exhibits ground plan of stairs. Wall-string circular.

The radius of this circle at cylinder is eight inches; or sixteen on diameter from centre to centre of rail. There is no particular limit to radius. It may be ten inches, two feet, or more. Width of hall and height of story always regulate this matter.

To lay down position of winders. Let E F be face of last riser landing. Then make E C equal half the width of a square step. Commence at C, and set off on circle five divisions equal to C E. Next, square over H L, and draw one or two square steps. This done, draw wall string and divide L F into six equal parts. Mark position of winders, and enclose circle with tangents A, B, C, D. The upper part of wreath standing over line D K falls level; consequently that line is its ordinate.

The tangents and winders must now be unfolded in order to show pitches and height of wreath. This is given at Fig. 2.

Let margin on right be the edge of a board. Commence at any point, say A, and draw the line marked "Height." Next, draw B, C, D. The letters here correspond with those on plan, and are tangents unfolded from A to D. Let winders at Fig. 2 stand in the same position as those of Fig. 1. That is to say, the tangent lines and not the curve.

Set off the two winders below A. Also square steps. Let under side of rail rest on these. Set off half its thickness. Next, set off under side of rail above landing to suit long baluster, shown on square step. This done, set off half thickness of rail, cutting through 5. We are now ready to draw pitches of wreath and ramp connecting with it—these pitches being entirely discretionary from fixed point 5.

It would, however, be imprudent to have them on a straight line, say from 5 to E, as that would cause the upper part of wreath to stand too high over the riser C on plan, and make baluster on right and left of C much longer than any of the others. This will be presently shown.

Let us assume 5, 3 for the upper pitch, and 3 E for lower. Find height for lower part of wreath by squaring over 4 P, which gives P 2 the required height.

Next, find a direction for ordinate, by extending 2, 3 to cut at N, giving N P. Let A N on plan equal it. Join N C, this being the ordinate. Draw through centre of baluster parallel with it, cutting tangents. Again draw through those on right parallel with D K, cutting tangent D C. This done, transfer intersections made on tangents to that of winders on the right. The dotted perpendiculars show the position of balusters; also their variation in length when standing under wreath. Dotted lines on right and left of C show two balusters standing under pitch 3, 5, which are longer than those under 2, 3. Thus proving the necessity for two different pitches on lower part of wreath.

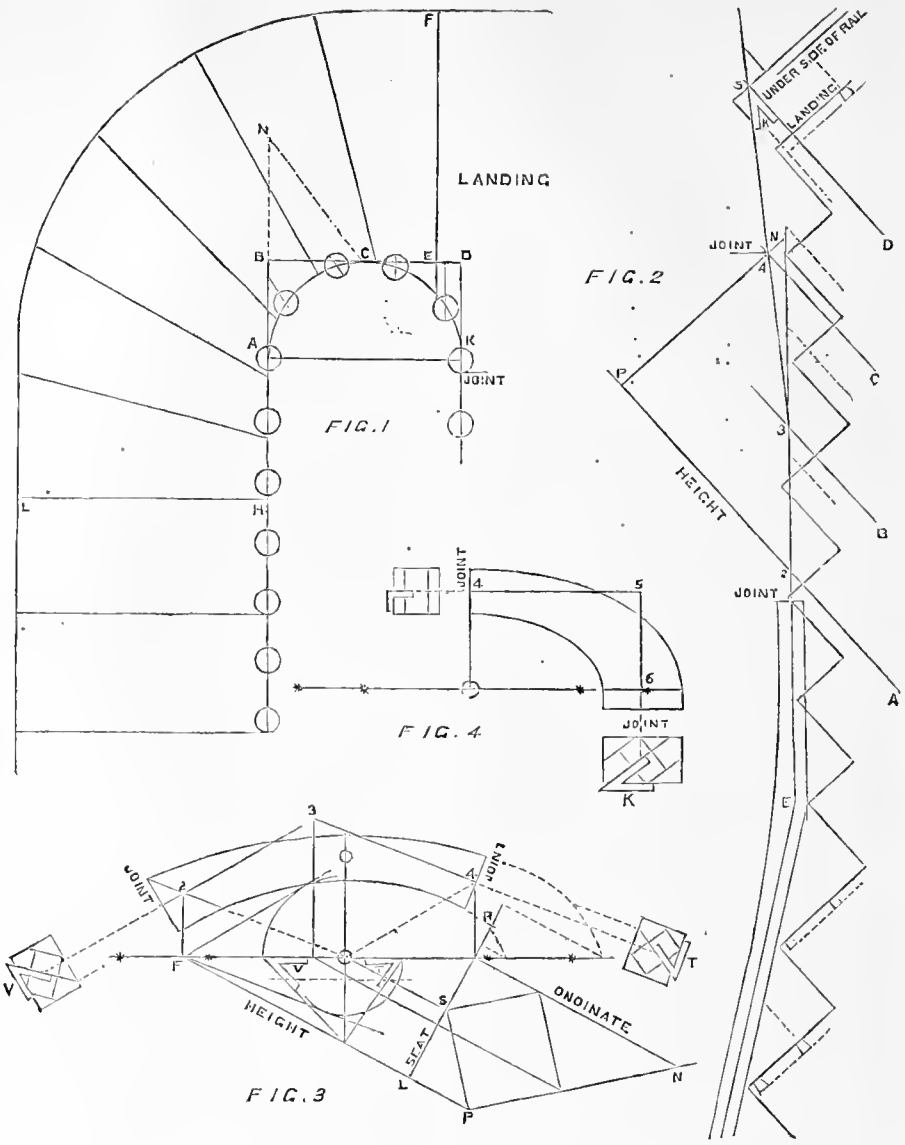
This should be adopted for all wreaths that stand over flyers and winders, landing on a level floor.

Fig. 3 shows construction of mould for lower piece of wreath. Let sides of square equal A B on plan. Extend any side, say P N. Let this equal corresponding letters at Fig. 2. Draw ordinate; also lines from the other three corners parallel with it. Next make seat square with ordinate. Let height L F equal that of 2 P on the right. Draw from F through intersection made by seat and ordinate. Thus giving pitch or major axis.

To find half the length of elliptic curves: Let S R equal one side of square. Then set off half width of rail on each side of R. This done, draw parallel with ordinate, cutting pitch. Next, square over the minor axis O O. Let this equal one side of square. Set off on each side of O half width of rail.

Proceed, and find points to insert pins for striking curves. This done let remainder of drawing be on a board intended for the mould. For example: Lay its edge on; mark all intersections made on pitch by lines parallel with ordinate.

* This series of articles is a reproduction of ROBERT RIDDELL's work on the subject, published in Philadelphia, and by Trübner and Co., London.



NEW ELEMENTS OF HAND-RAILING.—PLATE XVI.

Square them over. Next, transfer distances given by seat and corners of square. Then draw 4.3 and 3.2 extended. These, to be correct, must equal corresponding figures on pitches to the right.

To prove correctness of bevels and elliptic curves: Set off half width of rail below pitch. Draw parallel with it, cutting both bevels; that of T being for joint 4. Transfer the distance given on the right of T to each side of 4. Next, transfer that on left of bevel V to each side of 2.3. Then draw parallel with 2.3, cutting line O 2. Now insert pins, and sweep mould with a string. Then the elliptic curves pass through points just given; proving the accuracy of the work.

The reason why the bevel T applies to joint 4 is: the line from F, being parallel with tangent 3.4 on mould; then the circle touching that line, and cutting at T, shows at once where the bevel should be applied.

Leave no straight wood on convex side of mould. This gives the opportunity of slightly curving the lower part of wreath to connect with ramp, and removes that very objectionable feature —*a straight line;* which is often observed on the under and upper side of a wreath connecting with a ramp. This should never be the case, for it is just as easy to have bold and flowing curves, which give grandeur and effect to the work, as well as pleasure to him who executes it.

The mould, in its present position, represents the upper surface of plank. V T is the stock of bevels applied to lower surface. Square sections show the joints, on which is marked the width and thickness of rail. Have lines, made by bevels, continued on under and upper surface of plank, and square with joints. Then the application of the mould is: to make its tangents fall over those on plank. The edges of mould, in this position, give the wreath its cylinder curves.

Fig. 4 shows mould for upper part of wreath. This drawing is simply one-half of a semi-ellipse, and may be made at once on the board intended for the mould. For example: Let the line 4.5 equal corresponding figures on pitch, Fig. 2; also 5.6 equal one side of square on plan. Then, by drawing 6 O extended, we have the major axis; the wide end shown on the upper pitch, Fig. 2.

Set off on each side of 5, half-width of rail. Then draw parallel with 5 D, cutting pitch. Thus giving wide end of mould.

The angles 5.4 and 5 D contain bevel K. Its application is shown at Fig. 4.

Have three or four inches of straight wood from joint to 6. Now set off, on each side of joint 4, half width of rail. Next, find points to insert pins; then sweep curves with a string.

The square section shows the joint. The thickness of rail stands between two slabs that are cut off parallel with surfaces of plank. Let the stuff be cut square through, and make joints square with tangents. Now lay mould on. Keep joint on its wide end fair with that of stuff. Let 5.6 stand opposite bevel line on joint. This done, mark surface along edges of mould.

The same application answers for the other side. The centre joints of this wreath are indicated by 4 on each piece. When brought together, the lines made by the square, and that of bevel T must stand exactly opposite, thus throwing both pieces in their true position.

This rule must be strictly observed with every wreath, no matter what its character or situation may be.

On dit that Mr. C. G. Mayland and Mr. T. Roger Smith are candidates for the office of architect to the London School Board.

Gaff's Trustees, Falkirk, are about to erect new schools.

THE SURVEYORSHIP OF BRIDEWELL AND BETHLEHEM HOSPITALS.

THE attitude assumed of late years towards the profession by corporations, committees, and similar public bodies is not an agreeable one to contemplate, and suggests some unpleasant reflections as to the causes which have induced the present condition of public feeling. It must be obvious to everybody who has given any attention to the subject, that architects are not trusted in the manner they formerly were; their honour and integrity are more frequently called in question, they are allowed less latitude and discretion by their employers, and there is a disposition to fetter them by the imposition of checks and safe-guards which are supposed to ensure their honesty and to prevent them abusing their clients' confidence. This feeling of mistrust is of recent growth. In the early part of the century, architects were entrusted with the expenditure of large sums of money almost without restraint, and their good faith and honesty were seldom questioned. Such men as Soane, Wyattville, Ware, and others less known to fame, had the disposal of considerable amounts entrusted to them; they conducted the whole of the financial arrangements as well as the architectural details of their works, and successfully maintained their independence, resenting, not unfrequently with acerbity, the interference of their clients in matters which they considered did not come within their control. The imperious manner of some of the elder architects, not only towards their assistants but also towards builders and clients, is a very remarkable feature in the history of the profession, and some of the anecdotes related in illustration are extremely amusing, not only on their own account but also on account of the striking difference they present in the relationship of employer to employed at the present time. Some few of the elder men still retain something of the traditional style of behaviour of the old school, treating their clients as if they were conferring an obligation on them, and refusing them almost any voice in the architectural arrangement of the buildings to be erected. These instances are, however, rare, and in the large majority of cases architects nowadays study their clients, humour their caprices, and consult their comfort and convenience in a way that would make the hair of some of the old practitioners stand on end could they witness it. The position of architect and client has been completely reversed within the last fifty years. Formerly, it was the architect who dictated to the client; now it is the client who dictates to the architect. The increasing number of persons who call themselves architects and the inferior social position they occupy, as compared with the architects of the last generation, have no doubt had much to do with the existence of this state of things. Formerly, an architect was as a matter of course a gentleman—a man of education and a man of honour, but this is not by any means a matter of certainty now, and the public have not been slow in observing the change that has taken place. This is the real explanation of the altered state of circumstances between architect and client, and architects have only themselves to blame for it, through their not being more jealous of the honour of their profession, and discountenancing irregular practices by its members.

In confirmation of the foregoing remarks, we may refer to the proposed appointment of a surveyor to the Hospitals of Bridewell and Bethlehem, which will very well illustrate the estimation in which the architect is held by the public. A printed paper has been issued by the hospital authorities defining the duties and position of the surveyor, as well as the emoluments of the office. His salary is to be £250 a year, for which sum he shall attend all committees, and all views when required, report on all repairs and alterations to the hospital property, make estimates, measure the work, and certify on completion. He will also be required to survey all houses and buildings before they are let, to report upon their annual value, superintend any repairs or alterations required, and draw the plans on the leases. Once a year he is to make a complete survey of the whole of the houses belonging to the hospitals, and report to the governors thereon, more especially with a view to prevent encroachments. He is also to keep for the governors, in books to be provided for the purpose, plans of all the London and country estates of the hospitals, but it is not clear whether he is expected to take the plans, although it would seem from the fact that the books for the purpose of containing them are to be provided that the plans have not been taken. And generally, he is to perform such other duties as surveyor of the hospitals as the court, the committee, the president, or treasurer may direct.

This last clause is important, and it might be desirable that the candidates should be informed more precisely what are the views of the court, the committee, the president, and the treasurer as to the duties incumbent upon the surveyor. Would he, for example, be expected to clean the windows, or would blacking the treasurer's boots be considered one of the services attaching to his office?

In addition to the salary of £250 a year, the surveyor is to receive a commission of 2½ per cent. upon the cost of all new buildings erected under his superintendence, provided the building so erected should cost £2,000 and upward, but for all other buildings costing less than that sum it would appear he is to receive no commission. This commission of 2½ per cent. is to include measuring the work, besides preparing plans, specification, and estimates, and superintending.

The governors reserve to themselves the right of obtaining other professional assistance, if they should think fit, especially when important new buildings are contemplated.

In the advertisement announcing the proposed election to the vacant post, it is stipulated that all candidates must send in answers to certain questions, propounded by the governors in a printed form in addition to their letter of application, both of which must be in the candidate's own handwriting. In this form the candidate is expected to state, beside his name, address, and age, his occupation for the last ten years (a tolerable probation), whether he has been connected with any public establishment, and, if so, in what capacity, and whether he has had experience in keeping accounts. It is difficult to guess the reason why information should be required as to the candidate's connection with any public establishment, and still more so why a surveyor should be expected to be familiar with keeping accounts, as is apparently expected of him, unless the governors intend to combine the two offices of accountant and surveyor under the clause which enacts that the surveyor should perform such other duties as the court, the committee, &c., shall direct.

We have every desire to speak temperately, but we can but express our conviction, derived from a perusal of the documents we have just referred to, that the governors of the two hospitals have cast a most unmerited slight upon the profession, and are endeavouring to obtain more work for less pay in a manner quite unworthy of such a wealthy and influential corporation. The salary offered is in itself inadequate, being less than that given by the principal City companies, while the duties are more severe and onerous, and the incidental advantages very small and scrupulously regulated. The annual expenditure of the two hospitals is stated to be between £25,000 and £26,000, they have considerable estates in London and elsewhere, and the duties of the surveyor in relation to this outlay and the proper care of their house property will absorb a considerable portion of his time. Then he is to attend all committees and views when required, which seems very unreasonable, as he cannot be required for such committees as committees on account, house committees, and so on: the surveyors to the City companies only attend views and estate committees as a rule. It would seem that the surveyor is to draw the plans of the hospital property on leases without receiving payment; if this is so intended it is a very shabby proceeding, as the cost of taking and drawing of plans on leases has always been paid to the surveyors of estates.

The restriction of the commission on new buildings erected under the surveyor's superintendence to a commission of 2½ per cent. is still less to be defended, and should be firmly resisted by the profession. The surveyors to most of the City companies and the London estates of noblemen are paid the full percentage upon buildings erected by them, and their cases are precisely similar. It is a very mean and dishonourable proceeding on the part of the governors to deprive the surveyor of what is really an appanage of his office, and limiting the amount upon which the half commission is to be paid to £2,000 is the climax of meanness. The salary of £250 is paid to the surveyor for fulfilling the duties of surveyor to the corporation, that is to say, surveying their property from time to time, reporting on the value of houses for letting or other purposes, making specifications for repairs, examining accounts, and so on; and if he is expected to act also as architect he ought in common justice to be paid for his services at their proper market value. It may well occur that the surveyor might be called upon to prepare drawings and specifications for three buildings in the course of a twelvemonth, each under £2,000 in value, to the aggregate let us say of £5,000, and the governors would thus obtain work which if paid for at the usual rate would have cost £250, and they would get the whole of their surveyor's other services without payment.

If architects are found to undertake work on these terms the public will soon discover that 5 per cent. is an extortionate charge and will consider 2½ per cent. ample remuneration. Has the Council of the Institute nothing to say with regard to this portion of the subject? The Institute lately addressed a remonstrance to two of its most talented members in consequence of their having joined in a competition in which the payment proposed was less than the scale sanctioned by the council. It unfortunately happened that no better result was obtained than the withdrawal of the two gentlemen from membership, which was probably not the issue desired by the council. It remains to be seen whether the Institute will in the face of this disappointment venture to remonstrate with the elder men who are candidates for the appointment of Surveyor to Bethlehem and Bridewell Hospitals.

CHATEAU NEAR ODESSA.

WE give illustrations (taken from the *Revue de l'Architecture et des Travaux Publics*) of the principal elevation, side elevation, sectional view, and ground and first floor plans of a chateau, near Odessa, Russia, designed in 1857, by M. Ruprich-Robert, a French architect, for Prince Mauouk. The climate of Odessa is a very trying one for the architect—very cold in winter and hot in the summer; his ingenuity is taxed to provide a building suitable for the inclemency of one season and the great heat of another. The chief feature in this building is the great thickness of the walls, by which extremes of internal temperature are to a great extent avoided. M. Robert was not entrusted with the erection of the building, and his designs were, in some instances, departed from. For the style of the building, the client seems to have been responsible.

The eighteenth annual meeting of members of the London Association of Foremen Engineers will be held on Saturday (to-morrow), at the City Terminus Hotel. The business of the annual meeting will be opened at 8 p.m., on the 7th proximo. The anniversary festival in celebration of the formation of the Society is appointed to take place in February.

THE CHURCHES OF LINDISFARNE.*

THE scheme of this work, we are forced to own, has been far better than its execution. It would also, in our opinion, have been better had the former been less comprehensive than it is. An archdeaconry must be uncommonly rich and select in its architecture if all the churches in it—old and new, ruined and restored — would bear illustration. As far as we can see, however, that of Lindisfarne does not differ from most others, in that no serious loss to the antiquary or lover of art would be sustained if a very large proportion of those with which Mr. Wilson has cumbered his pages should fall victims to friendly conflagrations. We regret also to say that the minority, which deserve a better fate, and there are many which do so conspicuously, are not presented to us by the photo-lithographs of this volume in at all an attractive manner. These dingy and blotted plates will neither convey much pleasure to the casual observer, nor much information as to the details of the buildings they represent to the architectural student. Nevertheless, Mr. Wilson has collected, with much patience, a mass of information with regard to the churches, with many of which he has been professionally connected; and we can safely recommend, in this respect, his example as one to be followed by other architects to whom the conduct of church restorations is committed, although we cannot speak as highly as we could wish of the manner in which he has carried out his excellent programme. Mr. Wilson dedicates his work to the memory of Lewis Rockalls Cottingham, who, he gratefully acknowledges, imbued him, when his pupil, with love and reverence for ecclesiastical antiquities. In the three preliminary chapters the author gives some interesting historical information about the See of Lindisfarne, which was founded A.D. 634. His account of the somewhat romantic and legendary history of the Saxon Bishopric, which has left few material relics behind, is very readable. We will, however, pass on to the second chapter, which treats of the period to which are due all the churches worth record in Mr. Wilson's long list. Lindisfarne Priory then arose in more than the glory of the Saxon Cathedral which had preceded it, and in 1080 William Cairleph founded there a convent of Benedictine monks, and abbeys were afterwards built in the district at Alnwick, Carham, and Newminster; priories at Holy Island, Hulme, and Brenckburn; ten religious houses in Berwick-upon-Tweed, and monastic establishments at Bamborough, Ambe, Warkworth, Holystone, and Alwinton, together with a host of churches.

The archdeaconry of Lindisfarne was founded in 1843, and is subdivided into the Rural Deaneries of Norham, Bamborough, Rothbury, Alnwick, and Morpeth. It is to be regretted that Mr. Wilson has not given a map of the district with his work, which would have rendered it easier to follow his description.

As might be expected, there are many points of correspondence in design to be found in these neighbouring churches, and it is the facility given for such comparisons which is the peculiar value of such a work as this which Mr. Wilson has produced. Thus, as he points out, several of the Early English chancels have a strongly marked resemblance, and some peculiarities are discoverable only in buildings on the property of Merton Colleges, proving the work in these cases to have been by an architect in their employ.

Remains of Saxon work are to be found in seven distinct places, in each of which a tower formed a portion of the work. Such features in later times seemed to have been universal, and used in that border county as places of refuge, and to have been therefore specially provided with a chamber in the first stage above the ground. Spires are but of rare occurrence, six examples only existing, and those only upon the sea-coast. This is a remarkable circumstance, as illustrating the strictly utilitarian principle which governed the use of such features, which are now introduced too randomwise, and without reference to the requirements of the position of buildings. Some very apposite remarks, which have a more general interest, are made by Mr. Wilson on the subject of masonry. He disputes the usual opinion that it is impossible to assign an approximate date to an ancient building, unless there are mouldings or tracery left; and he points out the features which he considers as distinguishing the work of masons in the successive centuries, which he asserts to be each characteristic and well defined.

Referring his reader to his perspective view of the church of S. Bartholomew, Whittingham (a reference, by the bye, difficult to make for want of a proper index), he calls attention to the difference in the masonry of the lower stage of the tower from that of the rest of the structure, an example of long and short quoins of Saxon work. The church of S. Philip and S. James, Rock, is selected as a characteristic specimen of Norman masonry, where the stones are 10in. to 12in. high, even, not larger than a man can lift, and laid in regular courses. Of this he says, "Eight centuries have rounded their edges at the interstices, and toned the amber sandstone down to a sad dove colour; but that is all, for the work of the Norman masons has stood well and flinches not, albeit the walls are filled in with rubble only."

A better masonry, of which a beautiful example exists in Brenckburn Priory Church, is distinctive of the Transition Norman style. This is excellent, firm, and compact. The stones are rather larger than those of the Norman masons, but like them laid in even, regular courses. "Intelligence and devotion," writes Mr. Wilson, "are to be read in every line of it. Whereas we feel, as we examine Norman masonry, that Saxon labourers carried the stones to and fro with protest and sighs, and perhaps with stripes from the Norman 'ingénieur,' their taskmaster. This work impresses us with its silent appearance of ready compliance. There is an aspect of calmness and acquiescence in it altogether captivating. We feel sure those who reared it believed they were doing so to the glory of the Most High." Here, verily, is a sermon upon stones, and one worth preaching.

"The Early English masonry," continues the author, "is also excellent and regular, but on a vast scale and massive. The narrow lancet lights left wide intervals of ashlar work, where all effect depended upon the finish of its execution. There is an air of austerity about it, but there is no shortcoming, nothing less, in fact, than a vigorous staunch perfection. But in the Decorated period, when cultivated taste began to luxuriate in exquisite combinations of geometrical figures for ornamentation, the workmanship of the masonry was well considered. In the length of a course, here and there we find a stone too unwieldy or too small. Where it is too large it projects into the course above it, and the level of the next one is obtained by the expedient of placing a smaller stone than the average upon the top of it, and where it is too short its full height is made up with a smaller one. By these patches a general appearance of regularity is maintained, and that appears to have been the extent of the aim. Where there was a surpassing window to come, full of gracious and deft lines of beauty—a song of praise, indeed—the Edwardian masons knew that the plain groundwork in which it was set would be but of small account.

"And so with Perpendicular work. In proportion as ornamentation increased in esteem, the perfection of the ashlar work was disregarded. The stones of this time are about twice as long as they are wide; they filled the space that was to be filled quickly; and all taste and intensity of feeling was lavished upon the beautiful windows, the sumptuous doorways, the laughing, leering, grotesque gargoyles, the dainty crocketing, the proud finials, the label terminations, the doughty corbels—the coigns of vantage, in a word, of the carver's art."

In modern work, smoothness, copied from Greek temples, came in vogue; but, after the revival of Gothic architecture—though at first the masons were left to themselves and worked as they had been taught — this smoothness was seen to be unsuited to it, and a kind of lazy, scabbled, or cat's-claw work was adopted—another mistake—to remedy that of the unsuitable smoothness. "But now," says Mr. Wilson, "we know that no part of an edifice is too inconsiderable to be passed over, and that to ensure beauty, fitness, and endurance every man employed upon it must execute his portion of the work with understanding and integrity."

With these excellent remarks, which we commend to our readers, we must now take leave for the moment of Mr. Wilson's useful, though not attractive volume, hoping shortly to return to it, in order to examine some of the more interesting examples of the churches which he has illustrated and described in its pages.

* "An Architectural Survey of the Churches in the Archdeaconry of Lindisfarne, in the County of Northumberland." By FREDERICK RICHARD WILSON, architect. Printed and photo-lithographed by M. & M. W. Lambert, Grey-street, Newcastle-upon-Tyne.

ARCHITECTURAL ASSOCIATION.

AT the usual fortnightly meeting, held on Friday evening last, the President, Mr. T. H. Watson, A.R.I.B.A., in the chair, the following gentlemen were elected members:—Messrs. J. Wheeler, C. E. S. Smith, H. Hall, W. Hammond, J. Harrison, and C. F. Chesterman.

Mr. GILBERT R. REDGRAVE then read the following paper

ON THE ARCHITECTURAL TREATMENT OF RUBBISH.

Wander where we will in nearly any direction out of London, we come finally to rather seedy market gardens, though "gardens" is indeed a misnomer for such vegetable workhouses, full of forlorn gooseberry bushes and worm-eaten cabbages. London, properly speaking, has no actual termination; it merges so gradually and indefinitely into its suburbs that there is no knowing when we are really out of it. We all know the process of getting out of it, however—the streets which become newer-looking, with the shops getting few and far between; then the terraces, with hungry, or, better, thirsty-looking public-houses at the corner; then some "detached villas," with apologies for gardens to them; and last of all, the building plots, and the placards "Dry rubbish may be shot here." "Dry rubbish?" Yes, the foundation of the London of the future—a city built upon rubbish, not always particularly "dry," by the bye, but good, honest rubbish. No need of describing it, I suppose. Every one has doubtless observed the obliquely-lying strata of brick-ends and road-scrapings, oyster-shells and cinders, which a section of it presents to us. Truly a fine foundation—an admirable subsoil for dwellings calculated to last—well, ninety-nine years, at any rate. What a splendid study, moreover, for the antiquaries of future ages do these kitchen middens present us with! What a shell-fish loving people we shall be thought! Talk about burning down houses in China for the sake of roast pig, Mr. Lamb, why, it will be nothing to the way in which our descendants will pull down their houses (if they have not already fallen down) in order to dig for broken crockery and other traces of our civilization beneath the ruins! But, joking aside, it is a strange thing, even in the heart of the city, to find what accumulations of so-called "made-ground" have grown up on the sites of even our oldest buildings. I believe that a thickness of 20ft. of such deposits is by no means uncommon, and that if we go down to the virgin soil we pass at last through traces even of Roman London—the old thin bricks and Samian pottery. Now perhaps you may have already guessed what my paper is about, and you may think that I have brought you here under false pretences. I certainly chose an ambiguous title, and I did so intentionally, as I know that the Association cares little for practical papers (oh, oh). As I

cannot treat upon any other than practical matters I must beg of you to bear with me in spite of my title. While on the subject of

SUBSOIL,

I may mention that in the BUILDING NEWS a week or two back I saw a paragraph describing a quarrel (about these very rubbish heaps I have been alluding to) at Liverpool. A certain Dr. Stallard had pointed out in the *Lancet* that to collect "refuse, consisting of ashes, fish-bones, lobster-shells, cabbage-leaves, potato-parings, old door-mats, broken pottery, and the thousand other perishable articles which the sewers will not remove" cannot fail to make houses built on such a subsoil unhealthy. Of course his opinions were disputed by another member of his profession —Dr. Trench—who entirely controverts this view, and says, "As a physician and chemist, I assert that all organic materials—fish-bones, lobster-shells, old mats, and other perishable articles—will, if left undisturbed in a heap of ashes and macadam detritus, be speedily destroyed by eremacausis, without the evolution of any notable noxious gases, and that long before houses are built on the spot it will be a firm yet porous foundation, better suited for health than our boulder clay." In the face of two such opposite opinions the Liverpool Health Committee, feeling incompetent doubtless to settle the matter themselves, are about to request Professor Huxley to select two scientific men to inquire into the subject, and we shall shortly know, therefore, whether it is as unwise from a sanitary point of view as it is structurally, to build upon rubbish. I can speak from experience of the odours evolved from heaps of road scrapings in wet weather, and with all due repect for Dr. Trench, I am forced to state that they are, even if healthy, very unpleasant. In the natural course of things, having spoken of the subsoil we come next to the

FOUNDATIONS.

It is the fashion nowadays to specify concrete, though they used formerly to take no end of precaution in the way of York flags and piling for all buildings of importance, leaving the minor buildings to shift for themselves, and *shift* they certainly will if built upon these porous heaps. "Concrete" is a very enticing word, and carries an amazing sense of security with it. I can very vividly remember the site of some good houses, not a hundred miles from South Kensington—which are now probably letting from £300 to £400 a year. This site was (after having been a market-garden) a very muddy pond, on which the children of the neighbourhood made rafts of the contractors' plant, and swam sailing matches with the wheelbarrows. In course of time the ponds (which had been gravel pits) were filled in with rubbish, and ultimately gave place to "first-class family mansions," with stucco in front and stables at the back, which mansions in a very great degree owe their stability to concrete.

CONCRETE.

Well, we all know a great deal about this—a mixture which is buried as soon as it is made, and which is all the better for being quickly covered over and forgotten. If we believe our specifications, and have any faith that it consists of one part of stone lime, and six parts of clean ballast, we also probably believe that after a short time it gets very hard, more especially after it has been "thrown into the trenches from a height of from 10ft. to 12ft." and has been "well-rammed." Now, without mincing matters, I will tell you at once that "concrete" is one form of *rubbish* I am going to treat of architecturally. For all the practical value which we derive from nine-tenths of the lime concrete used in foundations, we might just as well use the ballast without the lime. In damp situations—and the trenches are rarely very dry—the chalk lime never sets at all, and if there is any running water it all gets washed out of the ballast in course of time and dissolved away. Lias lime and grey lime are certainly free from these objections, but they are, comparatively speaking, rarely used. The chief fault in the use of concrete is, however, the way in which it is mixed. We perhaps have had experience of Thames ballast—a mixture of mud, coal, chips, &c.—and we specify "gravel"—a rich loamy mixture of pebbles, well covered with a coating of clay. This material is "knocked together," as it is termed, or turned over with enough lime to colour it, and it is then thrown at once into the trenches. One value of the lime, which is perhaps overlooked, is that in heating and swelling, which it does *in situ*, it may cause the ballast to fill out the excavations. For the lime to have any real value in incorporating the pebbles it must have a clean hard surface to attach itself to, and it stands to reason that a film of clay is the worst surface for the lime to lay hold of. Again, the proportion of pebbles and sand in the concrete requires very careful adjustment, for if there is not enough sand to fill up the voids in the ballast the lime can never do it, and the concrete will be worthless. I have somewhere seen, I think in Laxton's "Price-Book," some very excellent rules for ascertaining the voids in ballast, and for arriving at the quantity of sand which should be used in a given quantity of shingle. The manner in which this was to be done was to fill a measure with washed shingle, and then to find how much dry sand could be shaken down into it. I am afraid that this precaution is very rarely taken. There is no doubt that the only way to make concrete properly is the way in which it is scarcely ever made—at least I have never seen it made so—viz., to mix the lime and sand first to the consistency of a liquid mortar, and then, in a subsequent operation by mechanical means, thoroughly to imbed the pebbles in this mixture. The old Roman concrete we hear so much about consisted mainly of such mortar, in which were imbedded the broken brick and stone, which were used in much larger fragments than we are in the habit of introducing into modern concrete. But not only in the manipulation of concrete; I maintain that all our building trade customers are antiquated and old-fashioned, and that in spite of our advance in other matters we are terribly backward in all that pertains to the mechanical details and practice of the art of building. Concrete is one of the things which can be made a hundred-fold better by machinery than it can be by hand labour, and yet we have no simple and cheap contrivance, that I know of, for making concrete. Again, within the last thirty years Portland cement has come into pretty general use, and Portland cement concrete, or even concrete made from a mixture of Portland cement and grey lime, is infinitely better than simple lime concrete, and yet how little of it is used except for frame buildings and block-making. We have excellent materials at hand, and merely in order to save a little trouble in the mixing, or for the sake of cheapness, we compound with them substances which come fairly into the scope of an essay on rubbish. From the foundations we get next to the

FOOTINGS,

the domain of bricks and mortar, and here of all places in the building rubbish is rampant. Bricks, some hundred years ago, were carefully made of good clay and properly burnt in kilns—the use of wood for fuel and the confined atmosphere of the kilns gave them for the most part a red tint. In course of time, brickmakers—and particularly London brickmakers—found that they could do without kilns, and could make bricks of pretty nearly any loamy rubbish, burning them with breeze and small coal in heaps or clamps. The article produced in this way—and known in its highest perfection in the specifications of careful young architects as "good, sound, square, hard-burnt, grey stock bricks," but rarely seen in such perfection elsewhere—is a dirty yellow-coloured and very irregularly-shaped object, which is *the* building material of London. I have no fault to find with well-made bricks, either for their size, their colour, or their form, I think in all these respects a good brick is as handy and convenient an article as could well be contrived, and in many parts of the country bricks which are really good in all these particulars are manufactured at a price equal to or but slightly in excess of the price we are forced to pay for our London rubbish. Really, bricks get worse and worse every year, and in default of a fair competition or of any suitable standard to judge by, the only difficulty in passing materials on large works is to know how bad you may take them. I believe the acknowledged test of goodness will soon be that if a brick on being held up by one corner and vigorously shaken does not fall to pieces, it will be considered good enough to pass muster.

BRICKMAKING,

though perhaps hardly coming into the architect's province, deserves to be taken in hand by some one in authority. If we want good bricks for facing we have to get them from some distant part of the country, and to pay a long price for carriage; and good stocks for common work are really quite out of the question. As London is a brick city, and can scarcely ever become any thing else, it seems sad to have to record the steady deterioration of our London bricks, and the worst feature in the case is that there seems to be scarcely any remedy for this evil. The reason of it is very evident, if we visit any of the centres of the brickmaking industry. One fact stares us everywhere in the face—want of capital, and, consequently, want of plant. Go to Hammersmith or Blackheath; you will find the same state of things prevailing in nearly every brickfield you visit. You know the sort of thing I mean—a blind, broken-down old horse tramping round in the old-fashioned pug-mill or wash-mill, and a number of men and boys turning over the mud and cinders. None of the modern machinery for crushing and preparing the clay, no mechanical appliances for moulding and pressing the bricks; and, lastly, the very rudest and worst plan imaginable for burning them. In many of the provincial towns the cry for better bricks has resulted in the introduction of patent kilns, the use of powerful grinding and moulding machinery, and the production of an infinitely better material than the old one, at about the same cost. I question whether a similar outcry would produce much effect in London. The brick trade is in the hands of such numbers of small men, who find a ready sale for any rubbish they can produce, and the builders can afford to laugh in their sleeves at any protest we can make about "stock" bricks. Moreover, we must remember the prejudices of the men and the power they possess to combine against anything they don't like—and a dislike of machine-made bricks is, I really think, born with the British bricklayer. We can all remember the Manchester strikes, which were brought about solely by the introduction of a better kind of brick. This may perhaps be the reason which prevents capitalists from embarking their money in the brick trade with a view to the London market, but I am convinced that before long we shall see an effort made, in some way or other, to introduce a better kind of brick than we are accustomed to, and whether the men submit tamely to the innovation or drive the new material out of the field, remains to be proved. The secret of the dislike of workmen to machine bricks is, I believe, their great weight; and another reason I have heard alleged, but it seems an absurd one, is that it is easier to make good work with them, and consequently a master expects more work in a day out of a man using "patent" bricks. One would think that the difficulty of weight could soon be overcome, either by slightly reducing the size of the brick, or by making larger frogs in it. The lightness of our London "stocks" is due, of course, to the numerous interstices they contain from the burning away of the particles of slack and breeze which are incorporated with the clay previous to firing. A large frog is objected to, owing to the quantity of mortar it swallows up. While on the subject of brickmaking, perhaps a word or two about "patent" bricks may not be amiss. By "patent" bricks, I mean any kind of machine-made bricks, for whether the brick is so styled by the manufacturer or not, I find the men invariably speak of them as such. The most common plan of making bricks by machinery is to temper or prepare the clay in the pugmill, out of which it is squeezed in a continuous stream. This stream has a sectional size of the wet brick—10in. by 5in.—and it is divided into separate bricks by wires or other cutters at intervals of about 3¼in. The bricks thus roughly formed are sometimes burnt and sold in the rough as they are, or they may, when partially dry, undergo a heavy pressure in metal moulds, when they acquire the name of "pressed" bricks. Any process such as I have described, by which the clay after having been well tempered, is formed into bricks in the way stated, gives a machine-brick which can compare most favourably with the old hand-made ones; but there is another mode of procedure which is now becoming very common, and which, though a simpler and cheaper plan of dealing with the clay, results in a much less trustworthy brick. This is known as the "dust process," owing to the manipulation of the clay in a dried and powdered state. In this case the clay, after it has been dug, is ground under edge-runners or any other suitable crushing-machine to a fine powder. This dry, or comparatively dry powder, is then submitted to very heavy pressure, by which means the particles of clay are so consolidated that the brick may be handled, and after very little drying placed in the kilns. By this process the toughness and

tenacity of the clay is in a great measure lost; and bricks made in this way (particularly if they be slightly underburnt) are often broken by men tapping them with the trowel. The fracture, also, instead of presenting the streaky silky look of plastic clay, has a granular appearance, resembling sandstone. I have still to mention a variety of machine-brick which has been comparatively recently introduced, but which, for many reasons, deserves our attention—viz., bricks made of concrete, pressed in moulds. These bricks are of course unfired, and depend entirely for their strength on the cementing material with which they are compacted. In the neighbourhood of London we possess an admirable pit sand, with a very indifferent brick earth; and as London goes on spreading, we shall gradually enfold all our former brick-fields in the heart of the metropolis, and brick-burning will be out of the question. Some cheap and simple plan, then, of making concrete bricks, which will obviate the necessity of firing, and will enable us to make use of the gravel we dig out of our foundations, has still to be introduced, and will be a great advantage in London. I fear I have digressed sadly in order to speak of brickmaking, which is a subject which hardly concerns me. I was saying with reference to the footings of our buildings, that this was the place to look for bad bricks; and there seems to be a further tradition—that not only are all the bad bricks to go into the footings, but that the first course should be laid dry. Of course, if we think about the matter for a moment, it is obvious that not only should our footings be composed of bricks picked for their strength and hardness, but further that the cementing materials should be the best of their kind. And this brings me to the consideration of another description of rubbish—mortar.

(To be continued.)

THE NEW POLICE SANITARY ORDER.

THE Chief Commissioner of Police has not been a moment too soon in the step he has just taken for the prevention of the spread of contagious disease in common lodging-houses. The order issued empowers the inspecting sergeant whose duty it is to visit such lodging-houses immediately on receiving notice of the occurrence of a case of fever or other illness, if the Poor Law medical officer and the relieving officer have not arrived, to direct the removal of all the lodgers from the sick room. He will then call upon the Poor Law relieving officer and obtain his order for the medical officer's attendance on the case. If these functionaries refuse or neglect to attend, and there is reason to apprehend the spread of any contagious disease or danger to the person who is ill, the inspecting sergeant is to request the nearest divisional surgeon of the police to attend, and will further accompany him and report the result without delay to head-quarters at Scotland-yard. He will also immediately afterwards see a guardian or an overseer of the poor, or the clerk of the guardians, and acquaint them with the absence or neglect of their officers, requesting at the same time an order to remove and admit the sick person to a hospital or the infirmary of the parish or union; and then, in default of such order, he is to apply to the nearest hospital which admits such cases for a like order. He is to act under the surgeon's advice as to directing the keeper of the lodging-house to take the necessary steps for destroying or disinfecting blankets, bedding, &c. In disinfecting common lodging-houses or sick rooms in cases of fever or other contagious diseases, by means of carbolic acid, the following preparation is to be employed:—1. Carbolic powder; 2, liquid carbolic acid mixed with water in the undermentioned proportions: carbolic acid, half a pint, water, two gallons; to be well shaken or stirred before using. All that comes from the sick room is to be received into a vessel containing three or four tablespoonfuls of carbolic powder or half a pint of the solution of carbolic acid. A shallow dish containing half a pound of the carbolic powder to two pounds of sand well wetted with the solution, is to be placed in each infected room, and renewed daily. Cloths dipped in the solution to be suspended in the passage immediately outside the door of the room. The room to be ventilated by opening both sashes of the window. The door to be opened as little as possible. Useless woollen and other draperies to be cleared out of the room when the symptoms first make their appearance. Foul bedclothing or body linen to be well scalded with boiling water immediately on its removal from contact with the patient, then to be dipped in the solution diluted with three parts of water, and afterwards wrung out in pure water. Every part of the house to be sprinkled with the solution twice daily, and at least half a gallon of the solution to be poured down sinks, drains, &c., once a day. All glasses, cups, and other vessels to be carefully cleaned before being used by others. All unpaved earth in backyards or around infected dwellings to be well moistened with the solution daily. In case of death the body to be wrapped in a sheet kept wetted with the solution, and a pound of the powder to be spread over the bottom of the coffin. On the death or removal of the patient the apartment to be fumigated with sulphur in the following manner:—The chimney being stopped up and the doors and windows closed, four ounces of common sulphur are to be placed in a shallow iron vessel or on a shovel, ignited, and allowed to burn out. The person who ignites the sulphur to leave the room immediately. The bed, mattress, and carpet, and all woollen articles of body clothing and bed clothing, to be left in the room during the fumigation. The walls and ceilings of the rooms, passages, and staircases to be washed and limewashed. Half a pint of undiluted liquid carbolic acid to be mixed with each bucketful of limewash. During the prevalence of epidemic carbolic acid soap should be used for all purposes in lieu of the ordinary soap. Calvert's carbolic acid to be always used.

Building Intelligence.

CHURCHES AND CHAPELS.

ALLHALLOWS, LOMBARD STREET. This church, which has been closed for several months, was reopened on Friday afternoon. The present building was reconstructed in 1694 by Sir Christopher Wren, and its main features have been faithfully preserved in the present restorations. The west galleries have been removed, and also the room at the north-west corner, throwing open the fine vestibule, the west window, and the groined ceiling. The wall and ceiling decorations have been carefully studied. On the ceiling, the corner medallions represent the Evangelists, the central subject being a figure of our Lord in glory. The more salient parts of the cornice mouldings are brought out in gold and colour. The faces of the groins under the main ceiling have foliated enrichments, with medallions, representing at the east and west ends the four great prophets; the side medallions, patriarchs and kings. Arabesque decoration is carried round the window arches and above the wood panelling on either side of the church. The window at the north side of the chancel represents the Marriage at Cana in Galilee. On the south side of the church, commencing from the organ, the subjects of the four windows are:—1. Christ Sitting in the Temple. 2. Christ Healing the Blind. 3. The Good Samaritan. 4. The Three Maries at the Sepulchre. The west end has a striking representation of the Crucifixion. On the north side, commencing from the vestry, the subjects of the four windows are:—1. The Wise Men's Offering. 2. Christ Raising the Widow's Son. 3. S. Peter Walking on the Sea. 4. The Entombment. The cost of the restorations has been £4,000. The architects are Messrs. Francis, and the contractors Messrs. Dove.

AXMINSTER.—On Christmas Eve the parish church of SS. Mary and John the Baptist, Axminster, was reopened, after restoration at a cost of £1,200. It consists of a central tower, 72ft. high, between the nave and chancel; and in old times transepts projected north and south from the tower. These no longer exist, and the aisles run straight through from end to end, a length of 97ft. The south aisle is partly modern, being erected in 1800, and took the place of "Drake's Chantry." The north aisle is (as well as the greater portion of the church) of Perpendicular date. The restoration has comprised the removal of the old galleries, the reseating of the church throughout, and some external restoration. The architect is Mr. Edward Ashworth, of Exeter; the contractor Mr. John Digby, of Ottery S. Mary.

PETERTAVY.—The little church of S. Peter's Tavy, in the confines of Dartmoor, was reopened on December 29, after having undergone considerable restoration under the superintendence of the rector, the Rev. T. Gibbons. The building consists of chancel, nave, north aisle, chancel aisle, south transept, western tower and south porch. The restoration includes new roofing, pointing the walls, cleaning all the stonework, and substituting neat benches of pitch pine for the old pews.

BUILDINGS.

BRADFORD.—New premises are to be erected for the Yorkshire Banking Company at Bradford. The design has been prepared in the French-Italian style by Messrs. Lockwood & Mawson, Bradford. The principal feature of the design is in the angle formed by the two streets, where the grand entrance to the bank is placed. Coupled fluted Corinthian columns, supporting a pediment, form a deeply-recessed portico, in the centre of which is the door-way. Above the portico is a boldly-projecting three-light window, with columns of the same order, carrying a smaller pediment, the tympana of both pediments filled in with carved work. Above this, again, is a coupled two-light window, with shafts, then a rich frieze cornice and parapet, flanked by ornaments at each angle, terminated by finials, and from the centre rises a lofty Mansard roof, surmounted with iron cresting and finial, the front of the roof enriched with a kind of dormer, carrying figures. The lower story of the bank is rusticated up to the first floor, the same feature marking each of the angles in Bank-street and New Tyrrel-street, the rustication being continued up to the frieze both there and on each side of the principal entrance. The banking apartments are on the ground floor, lighted by lofty square-headed windows, masks forming the keystone to the window heads. The first floor windows are terminated with circular pediments, and have balconies, and on the second floor the windows are coupled. A bold cornice and rich frieze is carried round the building, and above that again is the parapet forming square panels, filled in with paterae. A distinctive character is given to each angle of the building as well as to the central portion. The line of the parapet is broken by chimney stacks of bold treatment and by handsome ornamental terminals, imparting a feature of unity to the whole design. In the tympanum over the central doorway are the arms of Leeds and Bradford. The cost of the building is estimated at £10,000.

LEEK.—The Alsop Memorial Hospital has recently been opened to the public here. The following is a description of the arrangements:—The chief feature is the two large wards, each 27ft. by 14ft., which are intended for four beds each; that of the males being on the ground floor, and the females immediately over it on the chamber floor. A corridor the whole length of the ward separates it on both floors from the men's and women's special wards (for two beds each), the operating room and the baths, W.Cs. and lavatories; and all this portion of the building is divided by the hall and landing over it from the more domestic department, comprising the kitchen, scullery, pantry, and waiting-room for patients and visitors; and above these are three bedrooms for nurses and assistants and the linen closet; there is also a commodious bedroom and store-room lighted by dormer lights in the roof. The mortuary is a detached building in the yard on the north side, and the washhouse and other out-offices are also detached. The hospital is warmed throughout by the hot-air apparatus of Messrs. Haden & Son, of Trowbridge, placed in the basement story of the building. The architect has given particular attention to the plan of ventilation. The passage of an uninterrupted stream of fresh air through the wards being secured, warmed by the apparatus in winter and in summer reduced to a temperature at least ten degrees lower than that of the external atmosphere; the vitiated air is drawn off by regulated outlets into separate flues in the chimneys. The good old fashion of open fireplaces has been retained in each room, in addition to the warming apparatus. The building is of red brick, relieved by plain and moulded stone strings, and the jambs, mullions, and heads of the windows are also of stone. All the windows have pointed arches in coloured brick and stone, with label mouldings, the spandrils being filled with pierced traceried stone heads or dark-coloured tiles. The roofs are covered with plain and ornamental tiles, with stone copings at the gables, finished by iron or carved stone finials. The woodwork in the interior is varnished without staining, the figure being preserved. The walls are coloured throughout in judiciously-selected

tints of quiet tone; those in the wards having a skirting of three courses of white porcelain-faced bricks instead of the ordinary woodwork, as being capable of more thorough cleansing in the necessarily frequent washing of the floor, &c. The fireplaces have mantelpieces of moulded stone; the jambs being filled with pictorial tiles and the hearths laid with glazed dark-coloured tiles. The architect was Mr. Sugden, of Leek, and the work has been executed, under his superintendence, by Messrs. Nadin, Hudson & Philips; the stone carving by Messrs. Williams, of Manchester.

A DISAPPOINTMENT.

WE have announced the appearance of two series of illustrations for the present volume, which we are sure will gratify our readers, viz., "Monuments of Art" and "Albert Durer's Engravings." We had hoped to have commenced the former in the present number, and in our next to have given the first of the Durer series. The dull weather has, however, completely thwarted us. The process, photo-litho., by which these illustrations are produced, requires bright weather for its successful accomplishment, and until it comes we must claim our readers' indulgence.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

To OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR. 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—J. Heywood, P. A. Rayner, J. G. Bland, M. Munro, Sherry, Wednesbury Local Board, R. G. Thomas, T. Drew, J. S. Bradbury, W. Fogerty, H. H. Statham, W. MacFarlane & Co., H. McMillan, Gilson Martin, J. T. Ryan, P. Auld, H. G. W. D., Gilbert Redgrave.

M. CARPENTIER.—Received. Will reply by post.
SIDNEY ROBJOHN.—Thanks.
EDMUND WINTER.—Received. You need not have put us to the expense of triple postage.
D. A. WALTER.—Such a work, if well done, ought to sell. Would not the photo-lithographic process suit you?

Correspondence.

PERCENTAGERS AND ARCHITECTS.

(*To the Editor of the* BUILDING NEWS.)

SIR,—We have all heard of people who while perfectly sane, and even displaying a high degree of intellectual power in regard to some subjects, are crazy on one point, at the mere mention of which they are liable to physical or mental convulsions of an alarming nature. I am afraid Mr. Garbett comes under this category. We are much indebted to him for many of his writings; and he has given us more good sense and sound reasoning about the theory of architecture in his little work on the "Principles of Design" than are to be found in most books I know of. But the percentage system of payment is to him like the red rag to a bull, and seems to goad him to a sort of divine fury which far overruns the traditional boundary between the sublime and the ridiculous.

I will say at once that I think the percentage system a wrong principle of payment, inasmuch as in theory of course it encourages outlay, and lays architects open to the charge of being anxious to see as much money as possible spent on a building. But I am unable to see how this differs in principle from Mr. Garbett's proposition of so much per square of flooring. It is only the same thing under a different name; the architect may just as well be supposed under that system to be anxious to induce all his clients to build bigger rooms than necessary in order that he may pocket more money. The only system that would not be open to the same objections would be that of each architect charging, as other artists now do, whatever he considers the value of his work to be, or whatever he thinks he can induce the public to rate it at. There would be certain advantages in this plan; especially that it would enable those upon whom great demands are made to follow the example of painters and sculptors, and raise their terms instead of accepting on the same terms more work than they can possibly look after, and getting it done by proxy. But it is a very hazardous thing, especially for young professional men, to attempt to break down a long-established custom of this kind; misunderstanding, and perhaps loss of employment, are pretty sure to follow such an attempt, unless made by the profession *en masse*. Nor is the matter of anything like the importance which Mr. Garbett assumes it to be. There are probably plenty among the more talented members of the profession who would concur in thinking the payment question a very subordinate one, and whose anxiety is more to do something worthy of themselves and of their art than to higgle about how they shall be paid. When Mr. Garbett insinuates that no one who is willing to be paid on the present system, and make the best of it, can have any true feeling for the art of architecture, he says what he must know to be nonsense; and when he stigmatizes those who do so as robbers of the public he says what is as uncharitable and uncourteous as it is in many cases totally untrue. A similar system runs through many other professions on which no stigma is supposed to be cast thereby. Mr. Froude said, in his inaugural address at S. Andrew's University, that the system of payment for literary work was altogether wrong, as it was paid for according to the length of an article instead of its merit. This is true in one way; but as a matter of business the present system is simple and saves much trouble; and does any one suppose that because literary men are so paid for their articles, therefore there are none amongst them who are totally above the temptation of writing for money, or of spinning out an article to make a guinea or two more out of it? The fact is that, human nature being what it is, there will always be, in all trades or professions, a numerical majority of inferior men whose chief object will be to make as much money as possible; and these will do the same whatever system of payment is in use; and there will also always be, we may hope, a numerical minority of superior men whose main object is to do their work in the world as well and honestly as possible, and be "content with their wages," provided they can feel that they have done their best. And I believe there is as large a proportion of this class in the architectural profession as in any other at present existing among us.

Not having the honour to be a member of the Institute, I am not concerned to defend that body, which is well able to take care of itself, against Mr. Garbett's prophetic ravings, which they would probably not regard as worth a serious reply. But it is a pity, on Mr. Garbett's own account, that he cannot see the bad taste of indulging in such unmannerly and over-wrought diatribes against respectable people.—I am, &c.,

H. H. STATHAM.

A PLEA FOR THE PERCENTAGERS.

SIR,—"E. L. G.'s" letters began about the ventilation question, a very important subject doubtless, but hardly likely to be cleared up by discussion in such a temper as he manifests. His allusion to the Palace of Westminster as "rubbish," and the failure of its system of ventilation as an instance of the botchery of the British architect, is particularly unjust, as everyone knows that department was taken out of the architect's hands and placed in the hands of a scientific theorist not paid on the percentage system at all. But soon the original question disappeared, and "E. L. G." dilates almost exclusively on the evils of the latter system, and the legal enactments he would have made to put it down.

Indeed it strikes me that the BUILDING NEWS is hardly the proper organ in which to propound such views. It has little or no influence with the legislative "powers that be." Architects, as a body, have no political influence but one solitary M.P. belonging to that profession. Why does not "E. L. G." advocate these views in the *Times*, already sufficiently disposed to pour contempt on the craft and its usages? Or why, above all, does not he organize a deputation to Mr. Ayrton, who has not only the will but the power to bring in a bill for the proper regulation of architects' fees, and the utter abolition of their unlawful and immoral system of percentage? Perhaps, after all, "E. L. G." is only joking, and does not mean it.

When it is mildly suggested by one of the unhappy percentagers that "E. L. G." ought in all fairness to show us some better system before we give up what is at present the only mode we have of getting our fees determined, "E. L. G." flies into a rage, and very unfairly retorts the question on the inquirer, "What! you call yourself an architect (which means, being interpreted a *deviser*), and you are incapable of devising how you are to be paid? Out upon you and your Institute for a set of incapables." Excuse us, "E. L. G.," but the onus does not rest upon those who are satisfied with the system to devise a better one, but on you who find fault with it. And your flying into a rage proves very clearly that you find it much easier to pour forth invectives against the existing system than to point out any other. It is always much easier to pull down than to build up. However, it is easy enough to "devise" other systems, and I will undertake to devise half a dozen in as many half-hours, premising that they will be no better, but much worse than the existing system; but if "E. L. G." (who thinks nothing can be worse than the percentage system) likes any of them better, he ought to show us, what is the real difficulty—how we are to get the public to accept the new system so devised. When it is accepted I suppose "E. L. G." will have it enacted that anybody who will not pay his architect according to it shall be punished by "fine, imprisonment, or flogging."

There may have been in former ages architects who practised the art for the pure love of it, and on such high æsthetic and ethereal principles as utterly to disregard such low considerations as the amount of their fees. I suppose it is one of these that we sometimes see depicted in the vignettes to architectural works, in monkish attire, working away with a pair of compasses at the head of a geometrical window, on a sheet of paper, not mounted, but loose and curling in a very picturesque but unbusiness-like manner. If such as these ever existed they are now, at any rate, to be numbered amongst the "extinct animals." There are some who affect similar principles nowadays, and profess to look down on others as "making a trade of architecture." But if they mean that they do not make a trade of it as well or more, I don't believe them. Whenever a Parliamentary candidate professes thoroughly independent principles, that he despises place-hunting and patronage, and seeks to enter the House for purely patriotic considerations, I always expect such a one, if elected, to accept the first berth that is offered him. And when I hear some architects professing a lofty contempt for others who endeavour to frame their specifications, estimates contracts, and accounts on strict business principles, I always expect to find the accounts and fees of the former to be infinitely more unreasonable and exorbitant. In putting forward the following systems, therefore, I profess none of these high æsthetic principles, but simply aim at "making a trade of architecture," and what is much to be desired, a good paying trade too.

First, in deference to "E. L. G.'s" anxiety for the conservation of our ancient monuments, which now suffer so much at the hands of percentage-paid restorers.

Let there be in each diocese appointed a chief architect-antiquary, and a competent staff of subordinates, who shall have charge of the cathedral and all other ancient edifices, and whose duty it shall be carefully to patch up in their places all remains of antiquity and preserve them from restoration. To take special care of all such things as rood-screens, piscinæ aumbries, hagioscopes, confessionals, pixes, and other remnants of the superstitions with which the Church was overlaid in the Middle Ages (notwithstanding that she has for three centuries past rejected them as "dangerous deceits"), and to see that the churches are made as useless as possible for the congregations of the present day, who audaciously expect to be permitted to see and hear, and who if they cannot do that in church will go to dissenting chapels for the purpose. As the duties of this functionary are so important, his salary to be at least equal to that of the bishop of the diocese. In fact, as some notorious church restorers paid on the percentage system manage to make as good incomes, less could not be offered. The benefits of this system would be that the funds now so wickedly expended in destructive restorations would all go into the pockets of the chief architect and his subordinates, and as little "outlay" as possible be incurred in disturbing the ancient works.

Second, if that will not do to meet the general requirements, suppose we have it arranged that architects are to get their fees beforehand, like barristers. A client, for instance, on sending any instructions to an architect (say for a house) is to inclose a fee, which the architect may return if

not considered sufficient, but if accepted, and the client soon after abandons the idea of building, the architect to keep the fee notwithstanding. This would assimilate the profession to the noble profession of the bar, which is so distinguished for high principle, &c., and which exerts such a beneficial influence on all who come into contact with it. The wise regulation about keeping the fee whether the work goes on or not would enable architects to take much less fees for works carried out than they get at present, as the cases of abandonment are so frequent.

Third, let a table of fees and charges for each distinct service be constructed, and taxing officers appointed to adjust architects' bills like those of solicitors. The following is a specimen of how it might be framed:—

	£	s.	d.
Perusing instructions from client..	0	6	8
Do. if long....	0	13	4
Letter in reply	0	3	6
Do., if voluminous .....per page	0	6	8
Conference with client	1	1	0
Do., if long	2	2	0
Designs per sheet as follows:—			
Royal size.....each	1	1	0
Imperial do. .....do.	1	11	6
Double elephant .....do.	2	2	0
Antiquarian.....do.	3	3	0
Perspectives plain..per square foot	0	10	6
Do., if coloured	1	1	0
Reports, specifications, &c., per folio	0	5	0

And so on. Now then, let not "E. L. G." say any longer architects are "incapable of devising" any other system of charge than the hated percentage system.

"I can call spirits from the vasty deep."
"But will they come when you do call for them?"

There are two parties to be consulted, and at present the most unreasonable and least manageable of them is the public, and let "E. L. G.," therefore, address his future diatribes to it, or some organ capable of influencing its opinion.

And here let me call attention to a singular piece of disingenuous reasoning on "E. L. G.'s" part. "All other men's work," he says, "to be paid for by measurement, and then so much per cent. of what is paid for their work is to be the pay for our devising of the same." Now this is an attempt to put the architect in an exceptional position as compared with other workers which he really does not occupy. The builder is paid by measurement it is true, but how is the *price* obtained? Refer to Laxton, or, if you will, to a useful little book by "E. L. G." himself, and you will find, "The following prices are calculated at so much prime cost of materials and labour *and* 15 *per cent. profit!*" Where is the contrast now, except that the builder gets three times the percentage of the architect? Both are "percentagers" beyond doubt, and so is the surveyor; so come now, "E. L. G.," is this fair? Anybody else might be excused for ignorance, but with you who know the whole "art and mystery" it is inexcusable.

But architects are only a small and comparatively insignificant portion of the community to whom his denunciations apply. If a proprietor, instead of investing in building, chooses to invest in stock of any kind, he has to pay in addition "brokerage so much per cent." If he bids for an article at an auction, he has to pay in addition to the price 5 per cent. to the auctioneer. The percentagers' (as "E. L. G." would say, like the devil's) name is legion, for they are many. Land and house agents, ship brokers, corn factors, and a vast number of other honest callings, according to him, should be punished in the manner aforesaid, as well as architects. And can we stop here? How are her Majesty the Queen and all the Royal family, the ministers, the judges, the army and navy, kept up? Horrible to tell, by percentages. Income tax, 6d. in the pound means simply 2½ per cent. But, says "E. L. G.," this is on income, not outlay. Well, then, if I want to lay out 2s. 6d. on a pound of tea, have I not to pay 6d. per lb., or about 15 per cent. on the outlay, to maintain the dignities before mentioned? If I determine to expend £100 a year of my income in renting a house I have to pay about 25 per cent. in addition for rates and taxes. And is it not too bad that poor architects, who have to pay all these percentages as they fancied for law, order, and justice, are to be told that to expect any percentages for their own work is an offence to be punished with fine, imprisonment, &c.? It is well for them that "E. L. G." has not the power to enforce these enactments, savouring so strongly of mediæval persecutions and the holy office.

It is quite true that Lord Kenyon, in 1793, with about as much reason as was recently displayed by Mr. Baron Bramwell in another architect's case, ruled "that a percentage could not be recovered." Peace be with him! many and sundry percentages have been recovered since, and the percentage system seems to be the one thing juries are determined to uphold. The arguments of "E. L. G.," and many others beside, and Lord Kenyon's ruling into the bargain, were all put in a subsequent case tried before Lord Ellenborough in 1817, and resulted in a verdict for the architect for the exact amount of 5 per cent. on the outlay. And since then no one has been able successfully to question it as the ordinary and legitimate mode of remunerating an architect. It is one of those things, to alter an expression of Lord Dundreary's, that "every fellow can understand." It is sometimes objected to it that it should not be applied equally to plain and enriched buildings, but there is no force in this objection. If a building be plain it costs less, and so the architect gets less than he would for a more enriched building. It would be different if the percentage were calculated on the *cubic content* instead of the cost. But being on the latter no injustice is wrought. There may be cases of frequent repetition in large buildings such as to furnish good reasons for reducing the rate, as there may be also reasons for increasing it, but depend upon it, no other system would work so well as a whole, and the public generally will never have any other, only it should be the business of the Institute and other such societies accurately to define the duties included in it, and fairly to apportion it for every stage in the work. And let every architect see that he gives good value for it, "a fair day's work for a fair day's wage," and he will reap the benefits in increase of business and consequent increase of emolument on the sound and rational, though much maligned, "percentage system."—I am, &c.

AN OUT-AND-OUT PERCENTAGER.

THE AIR AND HEALTH QUESTION.

SIR,—I am glad to find from "E. L. G.'s" letter on "Percentagers and Architects," in your paper of 30th Dec, that when I want to build a house, I can have it thoroughly ventilated at the very reasonable rate of 10s. per square of flooring, for the plan. At present I am one of the "wise men" who live in houses which other men build for them; but having lately seen several newly built houses, on which no expense seemed to have been spared in other respects, but on which effective ventilation is entirely ignored, I have taken an interest in the question why this should be. I do not see that the fact that architects are paid by percentages should affect the matter, since, if it is assumed that an architect's chief object is to enlarge as much as possible the outlay on which his percentage is calculated, he may do so as well or better, in the means of securing good ventilation as in any other way. My impression is that most men who build houses for their own use have not studied the question of ventilation sufficiently to know its importance, or if they have looked into it, have found so many irreconcilable differences of opinion, not only on the details, but on the principles on which good ventilation is said to depend, by the leaders of opinion on the subject, that they have no faith in any of the systems recommended. And in either case they have gone to the best architect in their neighbourhood, and considered themselves safe in leaving the question to his discretion. Of late years, however, the importance of good ventilation has come to be better appreciated, and I feel sure that if any system by which a house can be thoroughly ventilated, without sacrificing other comforts and conveniences, is made public, architects, whether paid by percentages or otherwise, will find it to their interest to make proper provision for it. Reading everything I can lay my hands on that refers to the means of obtaining perfect ventilation, I have as yet found no practical system for ventilating and heating a house laid down by scientific men, of which both principles and details are not contradicted by other writers of equal authority; and under these circumstances I am not surprised that houses continue to be built as they are. Of those who know good ventilation to be necessary, a very large proportion believe it to be unattainable under any known system. Let "E. L. G." or any other writer on the subject, proves beyond question, that its benefits are attainable without relative disadvantages, and whether designed at a percentage, or at 10s. per square of flooring, the "Air and Health Question" will find that attention which it deserves. J. G.

NEW MASONIC HALL GLASGOW.

SIR,—I observed at p. 492 in your last number a notice anent the New Hall of S. John's-lodge, Glasgow, in which are several mistakes. I am not aware that said Hall really stands "due east and west," for upon consulting a large new map of Glasgow I find that, as it fronts Buchanan street, it must have a considerable dip towards the south at the east end. Then the chair for the Senior Warden is at the *west* end, not at the "east;" and there is no "Grand," but a *Junior* Warden. However these are only small verbal errors: the chief point of interest is the Hall and its decorations, which, in my opinion, are anything but satisfactory. Freemasonry delights in holding by what it calls "the ancient landmarks," or established usage—these, however, have in this case been discarded, and instead of the approved emblems, symbols, &c., being employed in an able, appropriate, artistic, and, if possible, improved manner, we find only a paltry, gaudy copy of an Egyptian tomb!

What on earth an Egyptian tomb, or temple either for that matter, has to do with a Freemasonic-hall I know not, more especially the hall of a lodge which prides itself upon being such a purely *craft* lodge. Were the S. John's-lodge intending to revive the "Egyptian Masonry" of the notorious Cagliostro, which flourished for a short time about eighty years ago, or to practise the rite of Misraim, or some similar tomfoolery, we might see cause why Egyptian symbolism should be copied, and gilded wooden sphinxes, &c., introduced, but as we understand such is not their intention we must consider their innovation a great mistake. Even the manner of carrying out the work is anything but good; the cornice is all executed in paint, and is most unnecessarily broken into in six different places, to the height of about nine inches, by six large ventilators, so shown off as if each one had a large poster on its breast with the inscription "I am a ventilator!" Then as a representation of "chaos," we have the circles of a shooting-target with a thunderbolt striking the bull's eye; and for "light" we find a large yellow gowan, or "sun," about two feet in diameter pasted up against a lot of dirty muslin, alias "clouds," I suppose, the effect being rather more allied to the ludicrous than the sublime. So much for masonic artistic decoration and architectural forethought and propriety in Glasgow!

I sincerely hope that any such sham gingerbread work will not be again attempted in Glasgow. It may perhaps please the vulgar and ignorant to see a lot of gaudy flaming colour stuck up all around them, but any person of good taste is sure to be disappointed.

The proper plan to do would have been to improve upon S. Mark's, just as the old thirteenth-century cathedral builders did upon the works of their predecessors; any paltry copying, or attempted revival of an old dead style, is seldom satisfactory. We might as well go back to the old Egyptian style in the carriage of our goods.—I am, &c., MASONICUS.

STYDD CHAPEL.

SIR,—No doubt others as well as myself were interested in the description in your last number of the ancient little edifice called Stydd Chapel. Those who reside in the locality would do well in caring for the fragments that may occasionally get dislodged from the building. In going round this chapel a few months ago I observed a fragment of stone, almost lost to sight amid a luxuriant crop of nettles, which puzzled the old sexton, my guide, to account for; but after clearing away the nettles I soon discovered that it was the apex of the coping at the east end, pushed off by the vigorous old ivy. Provision is made in the centre of this stone for a cross. I hope before long this fragment may be restored to its place.—I am, Sir, &c.,
Preston, Jan. 3, 1871. P. B. B.

Intercommunication.

QUESTIONS.

[2081] BOOKS.—Would "E. L. G." kindly inform me of the price and the publisher's name of Sir W. S. Harris's work on "Thunderstorms," written in 1827, and of the pamphlet by same author, published 1847, and referred to by "E. L. G." in "replies" column, BUILDING NEWS, Dec. 9, 1870? and oblige—BOANERGES.

[2082] DRYING BOARDS.—I shall be glad to know the best method of drying boards by the heat from the waste steam pipe which now passes from the engine cylinders to the chimney. Also, will mere steam dry boards, supposing it turned direct among the boards from the waste pipes? Or if not, will it have a good preparatory effect by causing the boards to dry more quickly when exposed either to hot air or to sun and wind afterwards?—K. K

[2083] HIGGS' PROCESS.—In the Act of Parliament for the improvement, &c., of the river Lee, 1868, the 101st clause refers to "Higgs' Process" for purifying the sewerage water passing into the said river. Would you kindly advise as to the nature of "Higgs'" process on this matter of purification, &c.? Can any reader give any information respecting this process?—G. W. M.

[2084] DESTRUCTION OF WOOD.—I have just been inspecting a house in which the woodwork is full of small perforations usually called wormholes. This prevails to a great extent in various parts of the building; it also affects the furniture, which is being rapidly destroyed. I should be glad if any of your readers could explain the cause and suggest a remedy. It seems to attack equally beech, oak, mahogany, and deal.—B.

[2085] ARCHIMEDIAN SCREW VENTILATORS.—Some information as to the properties of this article and the amount of air extracted in a given time according to the size, the various points to be considered in its application, &c., would oblige.—Z.

[2086] ARCHITECTS' CUSTOMS AND RIGHTS.—May I beg the favour of information as to the custom and rights of architects and surveyors under the following circumstances?—A survey, valuation, and report has to be made of one person's third interest in property situated in three different localities. No. 1. Ten houses, say of the total value of £4,400. No. 2. Five houses, say of the total value of £260. No. 3. Land, say of the total value of £160. Now the question is, what percentage should be charged for such survey, valuation, and report; and whether estimated upon the amount of the valuation of the three properties together, or upon each of them separately; and whether upon the whole amount of the valuations or upon the one-third interest only in each case—No. 1, say, £1,350; No. 2, say, £80; No. 3, say £50; and what addit onal amount, if any, for correspondence, interviews, travelling expenses, &c.—ARCHITECT AND SURVEYOR.

REPLIES.

[2075] TO PRACTICAL CLERKS OF WORKS.—In reply to "Old Foreman's" questions on Dec. 23, as to walls built 2ft. 9in. thick with 7in. of brickwork inside, I should have thought "Old Foreman" would have known without asking any one that brickwork does not settle near so much as flintwork, and especially if the former is built in dry weather, so that the natural and evident consequences are, the brickwork stands firm and flintwork settles, and the walls have thereby a tendency to settle outwards more or less, according to height, which "Old Foreman" did not give. Also the stone quoins will be a little displaced in consequence of the weight coming down upon the long bonded or stretching quoins, which, so to speak, will act as a leverage and force them out without they are held in position by iron ties or bond of some kind, which "Old Foreman" appears to be short of.—I. O. U.

WATER SUPPLY AND SANITARY MATTERS.

SANITARY NEGLECT.—The thickly populated mining town of Camborne, Cornwall, has for some time had an extraordinary death-rate, in consequence of the spread of fever, and the public schools have had to be closed with a view to check contagion. Dr. Buchanan, a Government inspector, has just issued his report concerning the sanitary condition of the town, which is represented as exceedingly bad, and calculated to spread any epidemic. Nuisances abound, overcrowding prevails, and, practically, there is no drainage. The water supply has been very bad and deficient, and it remains to be seen what result will be brought about by a private company. Dr. Buchanan insists that nothing will meet the wants of the town but the adoption of the Local Government Act, which has been strongly opposed by the bulk of the inhabitants.

SANITARY SCIENCE AT COLCHESTER. — Dr. Bree, the senior physician at the Essex and Colchester Hospital, writes as follows to a medical contemporary:—"Sir,—Every week you report the spread of scarlet fever, small pox, and other contagious diseases. Your correspondents write to you very learned letters about the mode in which such diseases spread, but few of them notice the fact that the so-called sani ary reformers and inspectors have themselves very much to blame. In this town of Colchester the Board of Guardians have erected a hospital for the reception of contagious diseases, which has the following admirable facilities for spreading the disease among the inhabitants:—1. It is thrust in, as it were, between the east side of the workhouse and a row of cottages, eighteen in number, inhabited by poor people, the end of the pest-house being 40ft. from the nearest cottage. Beyond this row of cottages is the public road, in a hollow, and rising above the road are the gardens of one of the most populous parts of Colchester. 2. Abut ing on the pest-house on the west is the playground of the poor children of the union; and close to it is the pay-room, where the poor congregate to get their allowance. 3. To the north, about 100 yards or so from the pest-house, are the public water-works, with a large open tank, which supplies the town with water. Beyond, half a mile off, is the Idiot Asylum, but there is hardly any break in the intermediate houses. 4. To the south there is a continuous street of thickly-inhabited houses, communicating with the principal thoroughfare of Colchester. After this pest house had been raised above its foundation, the inhabitants of the cottages demurred, through their landlord, to the erection of such a building within twelve yards of their bedroom windows, and the Guardians requested the opinion of myself and the medical officer of the union as to the eligibility of the site, and we both condemned it, but it appears that a non-medical Poor-Law Commissioner had approved the site, and the Guardians determined, spite of our opinion, to continue the building. The subject was brought before the Commissioners of Lighting and Paving, and in consequence of their representation, the Guardians requested the Poor-Law Board to send down a sanitary inspector. Of course the sanitary inspector would not disturb the site sanctioned by one of his Board, and so the building went on. The Commissioners of Lighting and Paving now applied to the Sanitary Board of the Privy Council, forwarding to them a memorial signed by seventy immediate inhabitants. The Privy Council, however, wrote to say that the place having been inspected by a sanitary officer of the Poor-Law Board, they declined to interfere. Now Dr. W. Budd has proved, and every educated medical man of experience knows, that infectious diseases are conveyed by atmospheric currents from the sick room to healthy places all around them to a distance, according to Dr. Budd's deduction, of at least a mile and a half. But instead of studying the practical, our so-called sanitary reformers are enveloping themselves in a fog of microscopic gemmules, which they think may probably be the *vera causa* of infection; and while they are fighting about the gemmules they permit manufactories of contagion to be erected amid the residences of the helpless poor. The effect of the building at Colchester, on the minds of intelligent people, is that the whole system of sanitary reform may be comprised in the word 'humbug.' And, with all deference to constituted authorities and the Poor-Law Guardians, I am very much of the same opinion."

STAINED GLASS.

BLACKFRIARS.—A new apse containing five windows has just been added to Christ Church, Blackfriars road. These windows have all been filled with stained glass by Messrs. Lavers, Barraud, & Westlake. The centre window represents the "Crucifixion," the remaining four severally depicting "The Agony in the Garden," "Christ Bearing the Cross," "The Resurrection," and "The Ascension."

CITY OF LONDON SCHOOL.—The large west window at the end of the gallery of the City of London School has been filled in with handsome stained glass, the subject being "Our Lord Blessing Little Children." The size of the window is 12ft. high by 9ft. wide, and divided into three compartments, with mullions between. Each mullion is cased with looking glass. The work was executed by Mr. Charles A. Gibbs, Marylebone-road.

HOWELL.—The east window of the parish church of S. Oswald, Howell, Lincolnshire, consisting of two lights, has just been filled with stained glass by Messrs. Ward & Hughes, in memory of the late John Walter Dudding, Esq. The subjects are "The Baptism of Our Lord," and "The Institution of the Lord's Supper."

SHARROW.—A window has just been erected in S. Andrew's Church, Sharrow, to the memory of the first vestry warden of the church, Mr. William Whitehead. The window contains two subjects in the lower lights, viz., "The Offering of the Princes to the Tabernacle," recorded in Numbers, vii. The second subject represents "The Offering of the People for the Repairs of the Temple during the reign of Josiah and the Priesthood of Hilkiah," recorded 2 Kings xxii., when they were delivered unto the "carpenters, masons, and builders, to buy timber and hew stone to repair the house." The subjects are set upon an ornamental base, beneath a canopy upon a grisaille ground, enriched with lines of colour and surrounded by coloured borders. In the tracery, Moses with the Tables of the Law is the central feature, and in other parts Masonic signs are represented, indicative of the order to which the deceased belonged. The artist to whom the work was entrusted is Mr. T. W. Camm, of Smethwick.

STATUES, MEMORIALS, ETC.

HENRY KIRKE-WHITE'S MEDALLION.—About half a century since, a young American gentleman, Mr. Francis Boot, of Boston, caused to be erected in All Saints' Church, Cambridge, a tablet, with a medallion by Chantry, in memory of Henry Kirke-White. In the course of various architectural improvements and ecclesiastical innovations, the beautiful work of the great sculptor was dethroned from its position and relegated to the back yard of a Cambridge tradesman. There, till only a day or two since, it remained. On Wednesday week after eight en months of protest and remonstrance on the part of all persons interested in preserving memorials of gifted writers executed by illustrious artists, it was removed from its unhonoured hiding-place to the Chapel of S. John's College.—*Globe*.

MONUMENT TO THE LATE GEORGE M'CALLUM, SCULPTOR. There has just been erected, in the Dalry Cemetery, Edinburgh, a monument to this most promising young sculptor. It consists of a simple slab of freestone, in the centre of which is a bronze medallion portrait by D. W. Stevenson.

LAND AND BUILDING SOCIETIES.

LEEDS PERMANENT BENEFIT BUILDING SOCIETY.—The annual meeting of the members of this society has been held, and in issuing the twenty second annual report the directors congratulate the members on the continued progress of the society. The receipts for the past year have been as follows:—Contributions, £134,024 11s. 8d.; mortgages paid off, £47,525 12s. 6d.; loans, £64,386 10s. 7d.; entrance fees, £597 8s. 8d.; total receipts, £248,786 2s. The directors recommend that 2s. 6d. per share be paid to those members entitled to the same until the next annual meeting. This surplus of 2s. 6d. is equal to 3s. 6d. as paid under the old system, there being nothing to deduct for office expenses.

MERCANTILE AND GENERAL PERMANENT BENEFIT BUILDING SOCIETY.—The fifth annual meeting of this society was held recently at the Myddelton Hall, Islington. The report and balance-sheet submitted to the meeting showed that the number of shares issued to the present time was 757. The income amounted to £10,606 8s. 6d.; the receipts from investments amounted to £2,650 7s. 11d., of which sum £2,650 had been advanced upon approved leasehold securities, and the premiums derived therefrom amounted to £260. The repayments made by borrowing members amounted to £2,012 10s. 7d. The profit for the year, after deducting all expenses of management, enabled the directors to declare a bonus of 2½ per cent. in addition to the 5 per cent. allowed by the rules, making a total dividend of 7½ per cent. for the year. The report further stated that in consequence of the great depression in the building trade during the past year, the directors had deemed it prudent to limit the operations of the society. The report was adopted.

Our Office Table.

PLYMOUTH SCHOOLS OF SCIENCE AND ART.—About twelve months ago the Bishop of Exeter, in distributing the science and art prizes at Plymouth, pointed out at a public meeting the need of a new building for the science and art classes. One of the local prints has also recently called attention to the need of such a structure in such an important town as Plymouth. We trust very soon to be able to announce that steps have been taken for the furtherance of so worthy an object.

THE ROYAL ALBERT HALL OF ARTS AND SCIENCES.—We have to announce that the Queen has fixed Wednesday, the 29th of March, as the day on which her Majesty proposes to open the Royal Albert Hall at Kensington.

TIN-LINED PIPES.—Great stress has been laid on the value of tin-lined pipes for the prevention of poisoning by the use of water conveyed through lead pipes, and the subject having met with considerable attention in the New World as well as in the Old, the *Boston Journal of Chemistry* calls attention to the tin-lined pipes which have come into use there, and against which it emphatically warns its readers:—First, because tin by itself is often more readily attacked and dissolved by water than is lead; and second, that when placed in association with lead, if through any flaw the water has any contact with both the tin and lead, those metals are dissolved with increased rapidity. Galvanised iron pipe is just as dangerous, for in this case salts of zinc are formed, and gradually dissolved.

DETERMINATION OF THE PHOTOMETRIC POWER OF A RICH GAS BY DILUTION WITH A POOR GAS OF KNOWN VALUE.—The conclusions arrived at by Professor Silliman as the result of a series of experiments made with great care at the Manhattan Gas Company's Works, New York, are—(1) That in all illuminating gas we have a substratum of non-luminous gas holding in solution a variable volume of luminous gas (olefines). (2) That, when a gas is too rich in illuminants to permit of accurate photometric admeasurement by the usual standards of intensity, it may be diluted, with a poor gas of known value and volume, to such a standard as is consistent with the accurate employment of the usual photometric apparatus, its true value being then calculated from known values employed.

DEATH OF A CELEBRATED BELGIAN ARTIST.—Our readers will hear with regret of the death of one of the most famous artists of the modern Dutch school—Petrus van Schendel, familiarly known as "Candle-light van Schendel," which event took place in Brussels on Thursday, the 29th ult., in the 65th year of his age. Many of his paintings have been exhibited in London and the provinces, and have always attracted great attention on account of the masterly manipulation which was one of the chief characteristics of this artist, specimens of whose works are to be found in most of the principal collections in England and Scotland.

A CRYSTAL PALACE FOR NEW YORK.—A Crystal Palace is to be built in New York at a cost of a million and a quarter sterling, covering nearly 23 acres. The palace will be situated below the centre of the island, and only one block removed from Central Park, with several railways adjoining. The sources of income—rent, entrance fees of exhibitors, and admission fees from visitors—are calculated to produce 9,124,000 dollars. The upper story of this huge building will be an art gallery, lighted from above. Its length will be 3,760ft., its width 150ft. Above this story there will be one to be given free to artists as studios, and a library will be included on this floor. At each corner of the building there will be an observatory.

FOURTEEN YEARS' SANITARY WORK IN ST. PANCRAS.—The Metropolitan Board of Works, apparently fearful for its future existence, is collecting from the local vestries and boards details of the sanitary improvements effected during the fourteen years of its reign, "by this means to rebut the allegations that have been freely made as to want of energy on the part of the local authorities of the metropolis." The vestry of St. Pancras has furnished its quota of information in the shape of a printed Report, a copy of which is to hand. During the period between January, 1856, and March, 1870, more than 6¼ miles of sewers have been constructed at

its own cost, besides over 9½ miles at the cost of private individuals, 7,048 house drains have been laid, and minor sanitary improvements carried out in more than 20,000 instances. All the burial grounds in the district have been closed, and an extra-mural cemetery at Finchley provided, at a cost of £37,000. Public baths and washhouses have been erected, and used in one year alone by over 160,000 persons. Paving, road-making, watering, &c., contribute to swell the total expenditure in fourteen years to £884,774.

KITCHEN BOILER EXPLOSIONS.—A correspondent writes:—"Next winter let us hear no more of deaths resulting from the bursting of kitchen boilers, when the remedy is so near at hand and costs so little. One of the smallest safety fusible plugs, sold by the National Boiler Protection Company, Manchester, applied to any hermetically sealed kitchen boiler will protect it. The fusible plug should be screwed into the top of the boiler, and protected with a pipe, so that when called into operation the steam and hot water may be propelled up the flue. This fusible plug is partly made of a metal which melts at a heat a little in excess of boiling water; when, therefore, the boiler is sealed up by frost, the water soon becomes hotter than 212°, the soft metal of the plug melts, the plug falls to pieces, an opening is made in the boiler for the steam, and an explosion is prevented. Every hot-water heating apparatus should be fitted with one of these safety plugs, and is not safe without it."

THE NEW COURTS OF JUSTICE.—The tenders for the foundation of the New Courts of Justice were to have been delivered yesterday. About twenty-five of the leading contractors of London were applied to, but the conditions put before them were found so inequitable that the competitors unanimously agreed not to tender till these conditions should be modified in an equitable spirit. In some disputed cases that have lately come before the Judges, they have expressed their strong sense of surprise that builders could be found willing to sign such one-sided contracts as many of them have been accustomed to do, and their disapprobation of those who put out such contracts. The Institute of Architects have fully considered the question, and have agreed with the London builders as to what is fair and equitable, but up to the present moment the Office of Works is insisting on conditions which the judges in a late case (Jones *v.* S. John's College, see the *Times*, Nov. 11) condemned as one-sided and improper. The competitors have solicited a conference with Mr. Ayrton on these points, feeling every confidence that he will be willing to listen to reason in the matter. They have considered that there would be no use in sending in their tenders till this matter be arranged, as in point of fact by so doing they would be binding themselves to the conditions. So the matter rests for the present.

Chips.

The pupils attending the Bristol School of Art, Queen's-road, Bristol, have presented a handsome edition of Dr. Smith's "Classical Dictionary" to Mr. James Fewings, one of the assistant-masters, on the occasion of his leaving to continue his course of studies.

It has been resolved by the Glasgow Police Board to pave the Paisley-road, west of West-street, with granite, at a cost of £8,000.

We understand that Messrs. Lee, of Westminster, have taken the contract for the new works connected with the Harwich Harbour Defences.

The erection of a floating bridge for the Hooghly is stated to have been sanctioned by the Government of India. Mr. Leslie, the engineer concerned, will proceed to England shortly, and it is expected that the bridge will be actively commenced towards the close of next year.

Thomas James Smitheman, builder, of Brompton-road, was on Wednesday committed for trial on a charge of uttering a forged bill.

To make a new rope as limber and soft as an old one, boil it two hours in water, and then thoroughly dry it in a warm room.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—*Royal Institute of British Architects.*—"Considerations on the Selection of Building Sites." By Professor Ansted. 8 p.m.

FRIDAY.—*Architectural Association.*—"On Colour Decoration." By Mr. J. D. Crace, A.R.I.B.A. 7.30 p.m.

Timber Trade Review.

PRICES, 4th January, 1871, per Petg. std.:—

Quebec 1st quality floated pine, 16*l* to 17*l* 5*s*; 2nd do., 12*l* to 12*l* 10*s*; 3rd do., 8*l* to 9*l* 5*s*.

Quebec 1st quality bright pine, 18*l* to 19*l* 10*s*; 2nd do., 12*l* 15*s* to 13*l* 10*s*; 3rd do., 8*l* 10*s* to 9*l*. All broad widths from 10*s* to 20*s* extra.

St. John's 1st quality white spruce, 8*l* 5*s* to 9*l*; 2nd quality, 8*l* to 8*l* 5*s*; 3rd quality, 7*l* 10*s*; Gefle yellow deals, best quality, 10*l* 5*s* to 12*l* 10*s*; Holmsund battens, 8*l* 10*s* to 10*l* 10*s*; 3rd quality Gothenburg yellow, 8*l* 10*s*; 4th quality do., 9*l* 10*s*; Petersburg and Riga white deals, 8*l* 10*s* to 9*l* 10*s*; Wyburg yellow, 10*l* to 10*l* 5*s*; Petersburg yellow, 13*l* to 13*l* 5*s*.

Quebec spruce 1st quality, 8*l* 15*s* to 11*l*; 2nd quality do., 12*l* to 12*l* 10*s*; 3rd quality do., 8*l* to 9*l*; battens, 7*l* to 8*l*; pitch pine planks, 12*l* to 12*l* 15*s*.

Lathwood, per cubic fathom.—Petersburg fresh, 5*l* to 5*l* 10*s*; Swedish, 3*l* to 4*l* 15*s*.

Timber, per load of 50 cubic feet.—Swedish, 52*s* to 55*s*; Baltic best middling, 72*s* to 80*s*; do. good middling, 43*s* to 67*s*; do. common middling, 52*s* to 58*s*.

Lower Port spruce, per Petg. std., 7*l* to 8*l*.

The recent severe frost having to a great extent stopped building operations, the timber trade, as usual at this season of the year, is not very brisk, but the trade doing is healthy, and free from the speculation which has marked former years. The rumours of a war with Russia slightly affected the market at one time, and Russian goods are still high, but when the spring importations arrive there can be no doubt of a fall in prices. If otherwise we have plenty of good substitutes in Swedish goods.

BUENOS AYRES GOVERNMENT CERTIFICATE.—Translation:—We, the undersigned, at the request of Messrs. Jas. C. Thompson and Co., certify that the Iron Safes of Messrs. Chubb and Son, London, of which these gentlemen are agents, were exposed for several hours to the fire that took place in the offices of the National Government on the evening of the 26th instant; that in our presence they were easily opened with their respective keys; that the moneys and important documents they contained were found in perfect order, and that these safes are now in use in the National Treasury Office.—Buenos Ayres, July 31, 1867.

Signed
J. M. DRAGO, Treasurer of the National Government.
JOSE TOMAS ROJO.
JUAN M. ALVAREZ.

A true copy.—A. M. BELL.

A large assortment of these SAFES may be inspected, and lists of prices obtained at CHUBB and SON'S, 57, St. Paul's-church-yard, London; 68, Cross-street, Manchester; 23, Lord-street, Liverpool; and Horsley-fields, Wolverhampton.

WAGES MOVEMENT.

THE JOINERS OF LEEDS AND THEIR EMPLOYERS.—A meeting of the master builders of Leeds was held at the "Nag's Head" Inn, Upperhead-row, last week, to consider a notice received from the operative joiners, requesting an alteration of their working rules, and to rescind rules relating to arbitration. The notice to expire on the 1st of July next. The present working hours of the joiners are ten per day for the first five days, and six hours on the Saturday, the rate of wages being 6½d. per hour. The demand made in their notice is that nine hours per day for the first five days, and five hours on Saturdays be the working hours, and the rate of wages 7d. per hour; further, that a rule be made to prohibit piece-work in carpentry and joinery. The notice was fully considered at the meeting of masters, and it was resolved that the present time is inopportune for considering any such alteration of the joiners' rules.

TENDERS.

DORKING.—For villa residence, Holmwood, for Dr. E. Bird. Mr. E. B. J. Knox, architect. Quantities supplied by Messrs. Corderoy:—

		Allow or old materials
Lyon & Dudley	£2850	£91
Putney	2595	34
Shearburn	2594	30
Gammon	2397	25
Rags & Ramage	2355	57
Shermer	2244	28

LEAKE.—For restoration of chancel, Leake Church, Lincolnshire. Mr. Edward Browning architect, Stamford:—

		Deduct value of old materials.	Nett amount of tender.
Richardson & Roberts	£1660 0 0	£ 60 0 0	£1600 0
S. & W. Pattinson	1443 10 0	100 0 0	1343 10
Perkins & Son	1480 0 0	140 0 0	1340 0
Law & Son	13 3 18 7	120 18 7	1273 0
Halliday & Cave	1420 0 0	170 0 0	1250 0

MANCHESTER.—For S. Anne's Infants' school, Ancoats. Mr. Herbert E. Tijon, architect:—

Turley	£409
Gerrard	395
Ward	390
Herd & Eadie	368
Thompson (accepted)	360

N. B.—Plastering and painting not in this contract.

PEMBROKE DOCK.—For passenger station, Stone, lime, and sand provided. Messrs. Szlumper & Aldwinckle, architects:—

Jones & Johns	£660 0
Davies	580 0
Rogers	500 0
Thomas	493 0
Allen (accepted)	484 10

TENBY.—For passenger station at Tenby, on the Pembroke and Tenby Railway. Stone, lime, and sand provided. Messrs. Szlumper & Aldwinckle, architects:—

Jonce & Johns	£815
Davies	700
Thomas	695
Allen	659
Rogers (accepted)	560

BATH STONE OF BEST QUALITY.

RANDELL, SAUNDERS, and COMPANY, LIMITED. Quarrymen and Stone Merchants, Bath. List of Prices at the Quarries and Depots; also cost for Transit to any part of the United Kingdom, furnished on application.

BATH STONE OFFICE,
[ADVT.] Corsham, Wilts.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

WHARFDALE UNION, Feb. 9.—For plans, specifications, and estimates for the erection of a new workhouse, to accommodate 150 inmates, exclusive of vagrants, on ground situate at Newhall, near Otley. C. J. Newstead, clerk to the guardians, Board-room, Boroughgate, Otley.

WEST HAM DISTRICT, Jan. 9.—For the construction of about 940 feet run of 2ft. 3in. by 1ft. 6in. brick sewer, and about 330 feet run of 15in. pipe sewer, together with manholes and other works connected therewith, in the Romford-road, Stratford, E. Charles Wilson, clerk, Townhall, Stratford, E.

MUNICIPALITY OF COLOMBO, Jan. 31.—For the preparation and supply of the smith and founder's work required for the new public markets and municipal offices at Colombo, Ceylon. S. Grenier, secretary, M.C., Colombo.

BURNTISLAND, Jan. 14.—For the construction of a wet dock and other works within the harbour of Burntisland. — Wallace, town clerk, town clerk's office, Burntisland.

WAR DEPARTMENT CONTRACT, Feb 4.—For the necessary work and materials required in the performance of work and repairs, and supply of labour or materials separately, as required for the service of the War Department, to the buildings in the Permanent Barracks, camps, or property at Aldershott, and connected with the War Department property at or in the vicinity of Aldershott. Director of Contracts, War Office, Pall Mall.

WORCESTER GENERAL INFIRMARY, Jan. 14.—For the erection of an out-patients' department, and for making sundry alterations and additions to the Worcester General Infirmary. Messrs. Martin & Chamberlain, architects, Christ Church-buildings, Birmingham.

HEREFORDSHIRE, Jan. 31.—For the erection of farmhouse at Hegdon Hill, near Bromyard, Herefordshire. Ernest A. Day, architect and surveyor, Foregate-street, Worcester.

WAR OFFICE CONTRACT FOR TIMBER, Feb. 4.—For the supply of dry ash plank, of the very best and toughest quality, thoroughly seasoned. Forms of tender may be obtained from the Director of Contracts, War Office, Pall Mall, London.

THE BUILDING NEWS.

LONDON, FRIDAY, JANUARY 13, 1871.

CHIMNEYS.

MODERN chimneys, to a large extent, have two faults. Their architecture is a failure, and their mechanism is not a success. The problem, here as everywhere else, is to join the useful to the graceful, or, at the least, to the inoffensive. And here, as everywhere else, half the people who try to solve the problem leave out one of its conditions. Some of them seem to think that if a chimney is but ugly enough, there can be no danger of its smoking. The chimney doctor inherits the superstition which possessed doctors in general some centuries ago, and believes that whatever is disgusting must infallibly be curative. His cowls and tallboys are remedies precisely analogous to the toad's fat and skull scrapings which were once supposed to be all-powerful, and the supposition in each case is equally rational. Other people, again, leave the use of a chimney out of their calculations, and try either to hide it entirely or at least to disguise it. But in the result there is not much to choose between the two classes—between that which rejects architecture and that which rejects utility. In abandoning one, each misses both ; and the only difference is that the first class seeks for ugliness, and that the second inevitably falls into it.

We think that there is a very frequent connection between the two faults just named. Oftener than not they both spring from the same cause. If the British householder's body is poisoned with smoke indoors, and his mind with ever-present ugliness out of doors, both these inflictions are laid upon him by one uniform principle. They are results of that "Classic man's recipe for designing," of which we spoke the other day. They are among the penalties we must pay for evenness, and regularity, and sham simplicity. This is what we come to by following that plausible delusion—the modern Italian style. It is so grand and simple, there is no nonsense about it, and nothing done for show. So people fancy who are sublimely ignorant of the whole matter, whether they happen to be Prime Ministers about to build new Foreign Offices, or merely retired cheesemongers going to put up a stucco villa at Norwood. The truth is that everything in the style is done for show. It starts with a showy exterior, made to rule, without reference to the inside arrangements. It goes on adding to this pilasters, and cornices, and porticoes, for show and nothing else ; and it finishes by dwarfing or hiding the chimneys because they are not showy enough to match the rest. Its simplicity is a false pretence, kept up by falsehoods in every part. With a system of designing that begins on the outside it cannot be otherwise. The first thing it does is to make a rigid and uniform exterior ; to settle the position of every door, and window, and piers. The next thing is to squeeze the necessary apartments into this Procrustean shape ; to contrive, as far as may be, that the rooms may fit the windows and doors. It is like making a man's coat by the proportions of the Apollo Belvedere, and then pinching the man here and padding him there until he is somehow squeezed into it. This is how the beautiful symmetry of modern Classic is attained ; it has one model for every one, and with more or less difficulty compels every one into it. "And is not it the best model?" it says; "Where will you get a finer shape?" As to the shape, we answer, it may be fine enough in its place. But its place certainly is not on our back. What with the tightness of the coat at one point and the looseness of it at another, it is hardly wearable ; and if we cannot get a better one than this it would be a great relief to do without coats altogether, and go about in our shirt-sleeves. In other words, if we cannot have an architecture that will accommodate itself to our wants, and bend this way and that as we happen to require, we should be a good deal better off with no architecture at all. If, for instance, there is no style to be found that will deal with our chimneys and condescend to study them, we had better turn all styles out of doors together, and see what can be done for chimney construction when they are gone.

But fortunately matters are not so bad as this. It is not real, but only pretended architecture which refuses to look at facts and conform to them. It is not ancient Greek or even Roman art which follows so absurd a plan ; still less is it Gothic. It is nothing but the bundle of rules and mechanical prescriptions which calls itself Italian or Modern Classic, which the old Classic men, if they could only see, would be the first to laugh at. Nowhere else, in any assignable variety of style, is one ready-made exterior imposed on all sorts and descriptions of building. Wherever architecture has had a spark of life it has always had a power of adaptation. Its aim has been to fit every structure with that precise design which would suit it best. It never had so vain a wish as to make all its works grand alike. It kept its grandeur for grand occasions, its symmetry for places where symmetry was natural ; but it was not so much infatuated about either grandeur or symmetry as to keep up their appearance where it could not have them in reality. It had no love for a sham magnificence—a padded misfit. It treated every subject separately, and made the best of it, displayed its character, brought out its distinctive points, and put its very essence into palpable and visible shape. And what it did with buildings as a whole it did equally with each of their parts. In details, as in masses, there was no deception. The only question asked was, "What feature does the construction lead to?" That point once settled, the only course was to turn them to the best account. Some of them, in their unconquered state, were doubtless ugly, some discordant, some mean and commonplace. The modern Classic man would have hidden them away altogether, or disguised them out of knowledge with his dummy cornices and other stock-in-trade. The ancient architect, whoever he was, did just the opposite. He seized on their natural expression and developed it, brought it into harmony with the rest of his work, refined the forms, beautified the construction, and increased the utility of the detail, all at the same time. This is what the Middle Age builders did to the buttress ; and, though examples are scarcer, this is also what they did to the chimney. And even when the Mediæval style had vanished, its spirit did not die. In quiet nooks, in country villages, and out-of-the-way towns, where fashion failed to penetrate, people went on for centuries—nay, have even gone on to this day—doing their work on those principles of nature and common sense which we call Gothic. And here, in their manor houses, and farms, and cottages, which no one ever sketches or illustrates, there are chimneys to be found with a refinement and propriety for which we might search London in vain. The chimneys, in fact, are often the great feature of this unpretending domestic architecture. Their tall clusters rise high above the steep pitched roofs, —for utility doubtless—since cottage and farmhouse builders seldom spend money on show, but yet with a wonderful picturesqueness, such as our modern designers can hardly evolve with labor out of all their needle towers and turrets. Of course there are many living architects who give us chimneys worth looking at. Seldom, perhaps, do we see more effective ones than some by Mr. Norman Shaw in a design at the last Academy Exhibition. Mr. Pritchard, too, gives much care and attention to his chimneys, and the same thing might be said of many others. But their work, unfortunately, does not come much into our towns. Nearly all that we see in them are chimneys kept too low, that they may agree with a horizontal style ; chimneys which it was attempted to keep out of sight, but which have shot up a cluster of zinc and iron abominations, and chimneys which start from an outside wall with no projection or visible chimney-breast beneath them. They are all ugly, and all liable to smoke. They are built for the sake of modern Classic rules, in defiance of plain facts which every builder knows. If a chimney is not carried up high enough it will smoke ; it will smoke worse if there is a high roof or wall adjoining it; it will do so with equal certainty if its flue is taken up near an outer face of the house without sufficient thickness of brickwork to keep the cold out. But by Italian regulations we cannot have a projection for such an unheard of purpose as to keep a flue warm; and we cannot have a tall stack carried up to produce a good draught, because it would jar with the general horizontal effect of the elevation. In point of fact, neither Vitruvius nor Sir William Chambers have left many instructions on the subject. There is not a model chimney put forth by any great authority ; and as it would be heresy to invent one, besides being a good deal of trouble, the only thing that remains is to keep our chimneys as much as possible out of sight. It is unfortunate that this should make them smoke, and unfortunate that they should be disfigured by cowls and windguards in consequence of smoking, but you would not have us take any steps to mend them without authority! This, judging from results, seems to be the Classic man's policy as to chimneys. Two hundred years of such a policy, in this and other details, have left our town architecture what we see it. Surely it is none too soon that we are trying a different one, the policy of developing instead of disguising, the system which works from within outwards, which starts with construction and bases everything upon it. It is none too soon that we are breaking through these absurdest of rules, and learning that we may actually venture to do what is necessary and rational without first waiting to find whether some great man has done the same thing before us. It may be long before we are free from their influence. Their spirit, unfortunately, has penetrated where their letter is disregarded, and Gothic as well as Classic has been stunted in its growth by precedent and tradition. It takes time to fit a nation of slaves for liberty ; it will take time, after the bondage of two centuries or more, to convince us as architects that we may really think for ourselves, and more time yet to make us think wisely. But if architecture is to live it will be done, and we hope there are signs that it is doing now.

ROYAL ALBERT HALL.

ON Saturday an interesting trial as a further test of the acoustic qualities of the Royal Albert Hall was held. The band of the 1st Life Guards, under the direction of Mr. Waterson, attended at half-past two o'clock, and from that hour until past four various instrumental pieces were played. The selection was well made, affording an opportunity of hearing the effects of loud orchestral chords as well as the subdued tones of pianissimo passages, and two songs were also given by a lady vocalist, with accompaniments on a Kirkman pianoforte. The result was satisfactory ; there seemed sufficient resonance to insure uninterrupted vitality to the waves of sound, and there was but very little re-percussion, and that confined almost to one point on either side of the vast oval of the interior of the building. The vocal tones were heard remarkably clearly, and the singer appeared to be able to deliver her voice with unexpected ease. One lesson may certainly, however, be learnt by this trial, and that is that a most perfect verbal enunciation will be

necessary to all who essay to sing in the new building; in this instance it was impossible to catch a single word, so that although the sounds were most pleasantly audible, the fair vocalist might have been singing in any known or unknown tongue, so far as ability to distinguish was concerned. The trial was however scarcely conclusive; the scaffolding still remains in the centre, the glass inner dome is not yet complete, and the orchestra was by no means as full as would be likely to be employed at any concerts. Single sounds there can be no doubt of, but a large chorus of mixed voices, with corresponding magnitude of instrumental accompaniment, will probably produce results not as yet ascertained. One point, however, is quite clear, and that is that the trial of Saturday is thoroughly satisfactory as to the ability of the building to convey the sound, and that any difficulty that may on completion arise, can readily be met by drapery to the upper alcoves, and, if necessary, by opening spaces below and in the surface of the inner glass dome to lessen the effects of the inevitably very considerable disturbance of the atmospheric waves in the upper part of the building. A large number of visitors attended, who seemed to express a general opinion in favour of the satisfactory results of the trial.

ANOTHER PHASE OF THE YORKSHIRE RIVERS.

THE other week we called attention to the present state of the Yorkshire rivers, as represented by the Aire and the Calder. A Bill has been deposited in Parliament, to be brought forward next session, which proposes to deal with these two rivers effectually. It proposes to appoint a Conservancy Board for the basins of these two rivers, consisting of persons to be named in the Bill, of persons representing the owners, lessees, and occupiers of property within the basins drained by the rivers Aire and Calder, and of Corporations, Local Boards of Health, and other authorities within the same area, for the purpose of protecting those rivers and their tributaries from pollution and obstruction.

The two basins are proposed to be called the "Conservancy Area," which will commence, as to the Aire, at Malham Tarn, and as to the river Calder at the head of the Calder, north-west of Todmorden, and will include, amongst other places, Skipton, Keighley, Todmorden, Halifax, Bradford, Huddersfield, Dewsbury, Batley, Leeds, Wakefield, Pontefract (or, locally, "Pomfret"), Castleford, Knottingley, Snaith, and Goole. The Bill proposes to confer the following powers on the Corporations or other local authorities within the Conservancy area, and in their default to carry out the provisions of the Act then on the Board already named:—

The interception, or otherwise dealing with all sewage that now flows into these rivers or their tributaries, whether proceeding from towns, villages, or manufactories, and the defecation and purification and return of it into these rivers or streams; or it may be conveyed either into the river Ouse or the river Humber below Goole; or it may be applied to the fertilisation of any land which may be acquired for that purpose.

The promoters seem to contemplate carrying main sewers through or near to agricultural land before reaching an outfall; for they propose to take power to sell any part of the sewage to persons who may wish to avail themselves of it on the line of the sewer, or of any part of the residuum of it, in case a system of precipitation and defecation be adopted; and for that purpose they propose to take power to purchase any patent rights or licenses connected with processes that may be found to be effectual. This will give a stimulus to invention that has been wanting, while people who were inclined to give attention to this subject had no certainty of any process being adopted, however effectual it might be.

The Conservancy Board may compel all persons who abstract water from any stream for the purpose of manufacture, navigation, or any other purpose, to purify it before returning it into the stream or any river.

It is contemplated to impound the surplus waters within the Conservancy area by the construction of sufficient reservoir room, and to supply from these reservoirs any deficiency in the flow of water in the rivers and streams.

Existing drainage works may be taken for the purposes of the Board, so far as they are available, and all new works hereafter constructed by any Corporation or local authority, within their own limits, are to be executed according to plans prescribed or approved by the Conservancy Board.

The Conservancy area is to be divided into separate districts for the purpose of rating, the extent to which any district will be rated being proportionate to the benefit to be received, or according to the extent of the works required in consequence of the position or acts of the parties to be rated.

Power is to be given to the Board, and Corporations, and other local authorities to take lands, houses, and other property, compulsorily or by agreement; but in case of lands being taken by compulsion, a provisional order from the Home Secretary will be necessary, and the confirmation of that order by Parliament; and the Board, and Corporations, and other local authorities, and their officers, contractors, and servants, are to be enabled to enter temporarily upon lands in the Conservancy area for the purpose of carrying out the provisions of the Bill.

Our readers will agree with us that nothing can exceed the importance of the objects of this Bill. It will prevent the obstruction of the rivers and their tributaries by solid matter, which now raises the bed and contracts the banks of almost every stream, and thereby in many places causes serious floods above the obstructions, throwing water-wheels into backwater, injuring crops, and creating a damp and unwholesome atmosphere. It will prevent the fouling of the water, which is now done to such an extent as to kill all fish, and make the water stink in the nostrils. It will recover from the sewage now flowing uselessly down to the sea all those fertilising properties it is known to possess, either by a process of irrigation or by receiving the sewage into tanks, and there dealing with it in such a manner that the water may be clarified and purified before it re-enters the stream, while the fertilising elements will be retained along with the ponderable matter, and applied as ordinary manure to land, the one or the other process being adopted according to the locality and the lie of the land in relation to the main sewer. One of the best provisions of the Bill is that it will enable the surplus waters—of which there are large quantities in every valley—to be stored up and economised for use in dry seasons, and for the equal benefit of all. Waterworks reservoirs—that is, reservoirs constructed to store water for the use of the mills affected by the abstraction of water for the supply of towns, as a compensation for that abstraction—have already improved the value of mill property dependent on water-power, by giving a more regular flow of water in the streams, but these being partial in their application the benefit to the whole area or district is not fully developed.

The Bill may be opposed, and strongly, but its merits are surely sufficient to prevent its being thrown out. The opposition cannot be against the merits of its beneficial provisions, but will probably be on its rating clauses. Those who have a convenient "tip" at present for all their rubbish in the stream on which their works are situated will not like to lose it; and those who now pour their fouled water into the same stream from which they derive it, but below them, will not like to pay for a more cleanly and wholesome system; while those who are remotely situated from the river will think they ought not to be called upon to pay for the more direct benefit of others. And some of the corporations and local boards will think it an interference with local self-government, and the owners of land upon which the sewage is to be applied will object to sell compulsorily what is wanted. But we hope these will all vanish before the sterling merits of the proposed measure.

KELLY COLLEGE.

WE are informed it is finally decided that this college, the erection and endowment of which are provided for in the will of the late Admiral Kelly, shall be established at Tavistock. It was the wish of the testator that the building should be somewhere in his native county of Devon, but no particular place was stipulated by him. A great many landowners then, doubtless perceiving the advantage to their property of the proximity of such an institution, made very liberal offers of estates. The most liberal seems to have been that of the Duke of Bedford, who offered the trustees the choice of several sites at Tavistock, and, we believe, a large sum towards the endowment. The trustees, very wisely, await professional advice before determining which particular site in that town they will select.

THE APPROACHING INTERNATIONAL EXHIBITION.

THE time for the first of the Annual International Exhibitions approaches, but the demoniacal carnage on the Continent still rages. The French Provisional Government has, however, confirmed the proceedings of the late Imperial Government in regard to the Exhibition, which consisted in taking a piece of land from the Kensington Museum authorities, and erecting a building around three sides of a quadrangle at its sole expense. The one point in which the French have made a great error (says the *Art Journal*) is in the roofing and lighting of their halls. These rooms are of the same width as the English galleries—viz., 30ft.; they are 27ft. high. The ceilings are flat, with a louvre light in the centre, and the result is that there is a blank, box-like space between the louvre light and the ceiling; while both that surface itself and the whole of the upper part of the gallery is thrown into dense shadow. The object is said to have been to secure ample wall space for the display of tapestries or painting. At any rate, it is a serious blunder, which contrasts very strongly with the good lighting of the English galleries.

The northern aisle of the Royal Horticultural Conservatory is to be widened and altered in form, so as to serve as a rain-proof court immediately adjoining the Albert Hall. The large upper corridor of this building is also being prepared for the display of pictures on the occasions of the exhibitions. There will thus be a continuous covered walk along the 1,200ft. of gallery, through the circular passage and conservatory, round the corridor of the amphitheatre, and so down to the gallery on the west of the gardens, which is of equal length with that opposite. When it is remembered that these galleries cover two floors, and that the French court has to be taken in addition, it will evidently be a good day's work only to look through the exhibition. A feature which will be novel, and, we trust, instructive, will be the display of architectural drawings. Continental architecture will be fairly represented; and we trust that the architects of this country will not allow the verdict to go against them for want of putting in an appearance.

THE INDIAN PUBLIC WORKS DEPARTMENT.—The case of "negligence, incapacity, and corruption," referred to on page 3 of our last number in connection with the administration of the Indian Public Works Department, forms the subject of comment by the *Spectator*. Our contemporary says:—"Lord Mayo is energetic, but neither he nor any other man can root out the vices of this department until he has a service of men who can do the actual work, and yet be trusted not to steal. At present the actual builder usually steals, while the officer who is supposed to look after him, and who does not steal, is so loaded with desk work that he is compelled to trust the untrustworthy subordinate."

ARCHITECTURAL DRAWINGS BY MR. W. BURGES.

IN the notice of this work by Mr. Burges in our last week's issue, we gave a general description of it, and the author's account of of its history; and we conceive that such must be more satisfactory to our readers, and particularly that large portion of them to whom the book itself will not be immediately and readily accessible, than if we had endeavoured to display our own learning and intelligence by an hypercritical search for its shortcomings. We do not wish to be reckoned among those critics who look upon an author as having taken up an idea of their own, and therefore open to the harshest judgment for not having carried out to an ideal perfection the project of another, but when we find a good thing well done we desire to be therewith content. Nevertheless, it is of course important to maintain a high standard as the aim which all authors should be expected to set before themselves, not only as an example to others, but also because by occupying the ground they prevent another labourer from undertaking the same work hereafter.

We have a right to look in the case of every publication, first that it should present a good and obvious raison d'être, and secondly, that in point of execution it should be thorough and masterly. We might excuse in the plates of the Architectural Association "Sketch-Book"—avowedly the tentative efforts of students—a lack of such qualities, but not so in a work which is a deliberative undertaking of a matured professional man. We have often called attention to, and deplored the manner in which English authors of architectural publications are apt to flit about like butterflies, with too wide and objectless a range, rather than, like steady-going bees, bent upon laying up good store for future use, and we have been positively provoked with the transient nature of the glimpses thus given us of things which we would fain have studied. Certain well-known architectural gems have thus afforded a subject for a sketch in half a dozen different works, but we may turn from one to another, and perhaps through the whole, without getting more than glimpses from each from varied points of view of what we are seeking to know, the anatomy and construction.

At first sight the reading of the titles of the plates in this work of Mr. Burges's would lead us to think that we were to be treated to the same superficial style of fare. The same well-known names, from as many, if not more widely-spread, localities, are to be found in the indexes of the previous works by Nesfield, Shaw, Rogers, and others. Is this, then, but another first-fruit of an architect's career, the gleanings of the grand tour made with the view of learning what others have done before him in the profession which he has chosen? Were it only this, we should not be inclined to admit that it had sufficient raison d'être.

That it is such, Mr. Burges freely admits; and to that fact may fairly point in extenuation of faults of style, which must perforce be attached to work of the class, for it would have been detrimental to the accuracy of his drawings to have striven to amend them in such particulars. It was because the manner in which the drawings were taken, with a view to the elucidation of the construction, and with regard to extreme accuracy in points of detail, was different to anything before done that they have been published. In the opinion of the author and his friends, in which we venture to say the architectural public will coincide, this was its raison d'être. It is no longer the picturesque outside of buildings that is presented to us, but a dissection of their interior construction. The drawings are copies of those which were plotted on the spot, and necessarily therefore devoid of graceful execution, although reliable in point of accuracy. Had the work been one projected and executed by the author at the present stage of his career, we might have complained of being dragged backwards and forwards between France and Italy and England and Wales after objects seemingly having but slight connection with each other; and we can pass over many a fault of drawing in what is in truth a note taken in a hurry to record some information, and the more readily because these notes have been transcribed for us by another hand, and must necessarily have lost something in the process. Next to the choir of Beauvais Cathedral, the flèche of that of Amiens occupies the greater number of pages; and the six plates (35 to 40 inclusive) in which its whole complicated construction is illustrated and explained is perhaps the ablest and most characteristic set of drawings in the book. Almost the entire structure, the measurement and plotting of which would appear an Herculean labour, is drawn to ½in. scale, with every tenon and pin, and the ornamental details again to a larger scale. While we wonder at the patience and skill displayed in the draughtsmanship, we feel lost in admiration at the constructive and artistic skill of Lewis Cordon and Simon Tameau, the carpenters, who were commissioned to make it, and who finished it in 1529, and whose work, with the exception of a few repairs to the woodwork, &c., Mr. Burges asserts to be now very much as they left it, although the method upon which they proceeded was an innovation upon the previous one of erecting wooden flèches, inasmuch as they did not trust to main beams of great strength, but made a sort of floor by means of trusses, upon which they built up their spire in the manner so well shown and described in these plates.

Chalons-sur-Marne supplies material for four plates, Nos. 9 and 26 from the Church of Notre Dame, and 52 and 53 from the Cathedral. In the first of these, while we find no erroneous lines of stone-jointing inserted, we think some important ones have been omitted, leading to the impression that some very queer-shaped blocks have been used in the construction, particularly at the junction of the two arches.

Troyes Cathedral—which Mr. Burges says, "unfortunately, like Beauvais, was not constructed in the best manner, and this, together with bad foundations, have rendered a rebuilding of a great portion of the work necessary,"—furnishes three plates (10, 11, and 27). These were taken under exceptionally favourable circumstances, the lamented rebuilding having proved "an ill-wind that blows no good," many parts having been reached which are in most cases inaccessible. We have, therefore, a section through the upper part of the choir, with all the details of its construction, and note in it that the usual third order of moulding in the tracery of the clerestory windows is dispensed with, and at the same time that the mullions are subordinated in width and decorated alternately with one and two columns in the same plane—an economical but hardly satisfactory contrivance.

Mantes Cathedral supplies in plate 14 an interesting stone roof over the vaulting of a chapel, and (15) specimens of richly-coloured roof tiling.

From England we have the rose window from the Temple Church, plate 13, and a dissection of the elaborate screen in Bishop Alcock's Chapel at Ely (plate 18), a more curious than valuable example of late date.

Wales contributes some details of battlements and curtain walls from the castles of Conway and Carnarvon, plates 23, 24, and 25, which, as Mr. Burges has gone out of his usual way to add some conjectural restorations, are interesting, particularly as it is somewhat strange that few reliable illustrations of these buildings have ever been made. From the Castle of Chillon on the Lake of Geneva, "probably one of the best preserved military edifices in Europe," we have, in plate 22 and the accompanying description, some interesting details, which doubtless have assisted the author in his recently-constructed galleries at Cardiff Castle.

France has furnished other architectural details from St. Omer, Villeneuve l'Archevêque, Amiens, Rouen, Beauvais, Dijon, Beaune, Noyon. The wisdom of the selection of some of these examples we are obliged to question, and would point to plate 32 to ask the reason that it is entirely occupied by a full-sized, certainly indifferent, drawing of a late capital from Amiens of no beauty, and unexplained by plan or section of the horns which bear the foliage, which alone would have rendered it of any value.

From Italy we have plate 12, from S. Andrea, Vercelli, two curious doorways; and plate 16, an altar from S. Maria Novella, both insufficiently filled; plate 20, a balcony from Padua; and 21, machicolations of Palazzo Vecchio, Florence, to which this same remark would apply, as well as partially to plates 31 and 32, which represent brackets from S. Antonio, Padua, and details from Vercelli; in the former of which, though the mouldings are given half full size, the foliage is hardly explained at all.

Some smaller objects of interest are given in various plates, such as a cross from the Museum at Chartres, and another from Molliuot, near Rouen, in plate 17; several fountains in plate 19; sketches of furniture from various sources, plate 59; the construction of the interesting Armoire in Noyon Cathedral, plate 61; the cope chest in that of Salisbury, plate 63; a Girouette, plate 67, one of the most valuable in the series; two chalices with all their details, plate 68; and the Crown of Constanza, plate 69.

The six last plates in the work are filled with notes of costume from manuscripts and samples of alphabets, which will be found useful for reference, but which will, we think, need revision if they are to be republished in another and more important form, as is promised.

Altogether, the collection is a large, varied, and useful one, though not such in arrangement or execution as we might expect from its able author had the drawings been undertaken with a view to publication in the first instance, or at a later period of his career. But then we must remember that it is not probable that any professional man could spare the time requisite for such a purpose after entering into practice, so that on the whole we feel we ought to be thoroughly thankful for what he has been good enough to give us.

ALTERATIONS IN CHEAPSIDE.—It is stated that with a view of correcting the narrowness of the Poultry the houses on one side are to be set farther back without pulling them down. If this answers it is to be hoped (says a contemporary) that the houses of many other streets will be "set farther back." The houses on both sides of Bond-street, Piccadilly, might with advantage be pushed back a few yards if there is any room for the pushing process. In S. Martin's-lane the houses might be pushed out of sight altogether. We want, in fact, some architectural police constable who will by a gentle tap of his official staff make all the houses in our narrow streets "stand back." They are a disreputable lot, and it would be far better to pull them down altogether, but if they insist on standing they should at all events not be allowed to obstruct the traffic. There is, however, one house in the Poultry which deserves a certain amount of respect owing to an incident in connection with it, related in Nichol's "Literary Anecdotes." The King's Head Tavern, No. 25, was kept in Charles II.'s time by William King. His wife happening to be ill on the day of the King's restoration, and anxious to see his Majesty, the affable monarch when told of her inclination actually condescended to stop at the tavern and salute her. It is also right to mention that Dr. Johnson met Jack Wilkes at dinner at No. 22 in the Poultry, which was then Dilly's, the bookseller's.

THE EXHIBITION OF OLD MASTERS AT THE ROYAL ACADEMY.

SECOND NOTICE.

THERE is a disposition among the art connoisseurs to cavil at the way in which the pictures at this Exhibition are placed. They should have been arranged, say they, according to country or school, or in chronological order, and thus the public might have been instructed and amused at the same time: why should our modern painters have to support the trial of being placed with the Italians, or with the Dutch? The natural answer to this is, Why should they not, since surely in our own minds we must place them somewhere? That they should be able to bear this juxtaposition in an exhibition as well as some of them do is more likely to raise than to lower them in our estimation. Besides, does it not excite a worthy emulation among living painters, so to strive in their art that they in their time may compete with the old masters, and do honour to the art of their country? We understand that in a second edition of the catalogue the Academy intend to place a notice, remarking that they have named the pictures as they are called by their owners, but do not give their sanction to such naming in every case. With regard to the much-talked-of Turner, No. 40, "Italy," we suspect that not only the Academy but the art world in general will find much difficulty in naming it. We have heard it ascribed by connoisseurs to be undoubtedly by three or four different painters. It is astonishing, now that doubts have been thrown upon this picture, how that the merest baby in art-knowledge "is SURE, the moment he saw it, that it could never be by Turner,"—how he declares that "it is a meretricious work, too hot, too leaden," &c., &c.—whereas, whoever may have painted it, it is a picture of real power and much merit. One thing is curious in the method of painting, which is, that it is too universally glazed. Now, Turner's pictures are rarely, if ever, glazed. On the whole, we are inclined to suspect that it may be the work of a water-colour painter. There are three Cromes in the first room; perhaps the best is No. 35, "A Landscape," with figures; it is much assimilated in tone to the pictures of the old masters, without becoming too heavy or black; the colours have darkened and enriched with time. No. 41, Reynolds's portrait of "Lady Ormonde and Child," is a very fine work. No. 51, "Hampstead Heath," is a very beautiful little Constable, evidently painted from nature on the spot. It is one of the most highly finished of this artist's works. Constable is well represented in the present collection, and his fine qualities being thus made known he ought to rise in public esteem. No. 14, "The Haywain," and No. 44, "The Cenotaph at Coleorton," are grand specimens of his art. It was while painting this latter picture that Constable complained of being put out of all feeling for his work, by the inopportune visit of a "little cocketty-hoop of a man," a critic, showing that then, as now, artists are of an irritable and impressible disposition. No. 13, Ruysdael's "Pool," is, perhaps, the most striking work in this room. Surely never painter gave with more truth and poetry the clear, calm, depths of still water. In Gallery II. is a most beautiful Cuyp, belonging to Lord Westminster, No. 66, "A View of Dort." The mellow light and the grey walls of the old buildings are both marvellously well rendered. There is in another room, though, perhaps a still finer specimen by the master, No. 209, "A Calm." The *on dit* about this picture is that it formed one of a collection bought by five gentlemen for £23,000. On dividing the pictures again amongst themselves by auction, the first bid made for this little Cuyp was £2,000, and it finally became the property of Mr. Baring, at £2,500, and although its monetary value is a poor one by which to judge a picture, this is certainly a priceless and perfect gem of art.

But to return to the second room: by the door, on the right, is one of Raeburn's best portraits, No. 54, "Mrs. Gregory." This, though somewhat painty, and treated in two pretty a manner, is, for Raeburn, a work of more than average merit. Near to it is placed a rather singular likeness of an old lady, No. 60, "Lady Harrison," by Sir Joshua Reynolds. Probably this portrait was painted when Reynolds had not as yet thrown off the custom of his master, Hudson, of painting the face and then allowing the dress to be added by a drapery painter; certainly the drapery has not the grace or even the air of being the work of Sir Joshua. Dyce is not so fortunately represented in this collection as we could wish; we should have preferred to have seen his "Good Shepherd" exhibited, or even his "Bemerton" or "Young Titian," in preference to No. 59, "Jacob and Rachel," which is but a small replica picture. Dyce painted this subject four times, and the best of the four, a very beautiful work, was in the Exhibition of 1862. His other picture here, "Joash Shooting the Arrows of Deliverance," is a fine and grand conception, though it surprised us to see the body of Joash of so inordinate a length; this is a curious mistake for the most academic of our painters and such a good draughtsman as Dyce to make. The first picture which attracts our attention in Gallery IV. is "The Daughter of Herodias," by Titian, No. 189. It is as fine as Raphael in drawing and lovely in colour. The woman is very beautiful, yet her beauty has something dreadful in it; the ferret jaw, and tight mouth, the finely lined eyebrow, the compact but little head, the defiant look in her eyes, and the sternly confident way in which she holds the head of the Baptist on the charger, all these combine to seize upon the imagination and impresses and disgusts at the same time. Did Titian paint this head from some young Venetian beauty? If so, and it is a portrait, surely there must have been something terrible in the woman's history. Nothing finer was ever painted in the Florentine school than the wonderful Veronese placed in the centre of the room, No. 188, "Our Saviour on the Mount of Olives, supported by an Angel." The subject is a very painful one, and it is placed before you with such awful distinctness that a public exhibition seems hardly the place in which to see it. Mr. Baring's Annibale Caracci, No. 194, "The Madonna and Dead Christ," though of an eclectic school, and seeking to combine all excellencies, fails in the tender and touching qualities in which the Veronese so excels. It is more posé. The mother bending over the dead Saviour is forced in expression, and the extended hand has not the action of unconscious grief; the fat little angels, too, are neither ethereal nor spiritual beings; yet this is one of the finest works of a school which fifty years ago was thought by connoisseurs to be second to none. The great qualities of the Dutchmen are very remarkable in this room. They are the greatest painters in the world, if we except perhaps one or two Venetians; the word painter here must be taken only of course in its technical sense. Let us compare Teniers and Ostade, both so great in such different ways. Teniers' execution is the most facile possible; he paints directly and with a onceness. Ostade, on the contrary, is as subtle in his methods as Titian; he prepares his different colours for glazing with the most varied precision, and lays his grounds with true Venetian feeling. De Hooge, again, works with astonishing minuteness, while he never loses sight of the effect he wishes to produce. He paints each brick, but does not forget the glow of sunshine which he intends should cover the whole pavement. The detail, though strictly given, is subordinate to the mass. No. 208, "The Tavern Door," is a fine specimen of the master, rich and glowing in colour; so is No. 175, "Woman and Child in a Street in Utrecht." It is rather sad that so little should be known of the life of such a truly great painter as De Hooge, whose works have attained to such celebrity. No. 190, "A Philosopher in his Study," by John van Eyck, is a very beautiful specimen of the master. There is a still finer van Eyck in a farther room, No. 326, "Celebration of High Mass." The finished and devout expressions of the faces should be observed; note, too, that each individual stitch in the worked carpet is painted, though the perspective is quite ignored. Lord Ashburton's two Ostades, No. 216 and No. 217, should be closely studied by art-students, as also should be No. 202, "Playing at Skittles," by Jan Steen. No. 190, "The Female Artist," by Metzu, is a fine work. No. 218, "Cows and Bull under a row of Willow Trees," by Paul Potter, is painted from the same spot, only looking in the other direction, as Lord Westminster's "Dairy Farm near the Hague," exhibited here last year. Perhaps the finest Turner in this collection is placed in the next room, Gallery V. It is glowing with light. Over it hangs Mr. Billing's Murillo, a good specimen of the master, and not black. In Gallery VI. is placed Raphael's first picture, No. 307, "The Crucifixion," painted when the artist was only 17 years old. It bears the impress of Raphael's master, Perugino, rather than of Raphael. It is unfortunate that the dark hard-lined girdles of the two angels on each side of the cross give the impression that they are supported by iron bands. No. 309, "The Three Graces," by Raphael, is, perhaps, at once the smallest and choicest picture in the collection. Fra Angelico's picture of Paradise, No. 313, has much of the tender sentiment and sweetness always pervading his works; the delineation of the tortures of hell must have been, we should think, very adverse to his holy, loving nature, and very appalling, no doubt, at the time they were painted, but of course in our days they are viewed as so treated rather with curiosity than with terror. No. 303, "Peter offering the Keys to the Infant Saviour," is, perhaps, the best picture by Crivelli here. He is a master of whom little is known, but his pictures have much that is remarkable in them. In this gallery, too, are placed many pictures by Perugino. The simplicity and grace of his compositions, and the purity and elegance of some of his figures, leave a forcible impression on the mind. His colouring, too, is very beautiful, notwithstanding the almost entire absence of any gradation of tint. His works should be carefully studied by the lover of art, for many germs of those beauties in which his pupil Raphael so excelled are traceable in this master's pictures. There is a curious work in this room by Blake, No. 285, the title of which is too long to give. To our minds, it is not a favourable specimen of the artist's powers. Some of his illustrations to Dante are of a much finer quality, though, being in water-colour, they would, perhaps, be inadmissible. Blake is said to have asserted that by forcing his darks he could paint on a mahogany table instead of a canvas, and make the mahogany tell as the light of his picture; to carry out, we suppose, the truth of the painter's adage, that if you want light in your picture you must make it darker. He has not been very successful in this method of painting in the present work, and has been obliged to gild his high lights in order to brighten the picture. It is a mistake to name Holbein as the painter of No. 296, "Portrait of Francis the First." The portrait is evidently the work of Janet, who was a French painter of that period, many of whose best works have, out of his native country, been ascribed to Holbein. The lecture-room contains one of Sir Joshua's most admirable pictures, No. 285, "Portrait of a Child in a Mob-Cap." It is simply beyond praise. Compare it with the mannered prettiness of Greuze's children, Nos. 392 and 398. Does not the quaint simplicity of the little maid in the mob-cap literally put them to shame? and yet the Greuzes are very beautiful in their way. Murillo's six pictures, or rather sketches,

of "The Prodigal Son," are placed in this room. We call them sketches, for such they are, and as such do credit to Murillo's talent. Until two years ago Lord Dudley possessed but five of these works, when being in Rome and seeing the sixth in the Papal Collection, he suggested to the Pope that to make the series complete they must one or the other give up their treasures, whereupon His Holiness made him a present of No. 6, and Lord Dudley presented in return a thousand pounds to the Pope's charities. Space fails us to give a more detailed account of the many admirable pictures contained in the present collection, and we can only beg our art-loving readers to take an early opportunity of visiting the exhibition, in order to examine and criticise the works for themselves.

ON THE ARCHITECTURAL TREATMENT OF RUBBISH.*

(*Concluded from page* 18.)

MORTAR.

I REALLY hardly know how to begin my crusade against mortar. I cannot say that we are getting worse and worse in this respect, for I am afraid that London mortar has always been to a great extent a snare and a delusion. I was watching some time back the old houses in Carey-street coming down to make way for the Law Courts, and on examining the brick rubbish on the site I found that the mortar, nearly all of it, crumbled into dust on being handled. The fact is that the purer limes, such as are known as "fat" limes, never can be made into really good mortar, and if the mortar made a hundred years ago was bad, it is sad to think how much worse a great deal of our modern mortar must be for want of due care in its preparation. I find that in Langley's "Price-book" for 1750 (our old friend Batty Langley) an equal amount of sand was the utmost it was thought possible for lime to carry, and when pit sand was used the lime always predominated. We now commonly specify two or sometimes three parts of sand, and I know from careful experiments that a skilful labourer will make one yard of lump lime carry 3¼ yards of pit sand, in spite of any specifications or directions to the contrary. But it was not in the materials and their proportions that our fathers so greatly surpassed us in the preparation of their comparatively worthless mortar. When we read of the time which was to be devoted to the beating of it, the slaking and softening of the lime, and the many precautions to ensure its excellence, we feel how far we are behind them in this respect. I have no wish to make out too strong a case against our mortar, but I will appeal to your own observations on the subject. Do we not invariably find the preparation of the mortar left to the most ignorant labourer on the place? Do we not find him to possess the haziest possible notions about proportions? Is there not in almost all cases a tendency for sweepings and suspicious rubbish of all kinds to get near the mortar heaps? And does not this rubbish very frequently disappear when our backs are turned in a remarkably sudden way? Our mortar is truly the veriest rubbish, and it is a bad kind of rubbish, for it pretends to be, and somehow it has come to be considered to be, good and suitable for the purpose. I am almost certain that much of our mortar might be very advantageously replaced by well-tempered clay. If this were well raked out of the face-joints, and the work then pointed with Portland cement, we should get a better wall than we do now with the mortar made of lime and road scrapings. The fact is, our mortar-making is the most hap-hazard and chance kind of work which goes into the building, and yet we must all admit that there is nothing which is more important. Here, of all places, we want to substitute the Irish labourer with some simple machine or mill, for milled mortar is, whatever may be the quality of the lime, a hundred per cent. better than that which is made by hand. It is quite true that we can employ the ordinary edge-runner, and grind together our sand and lime, and for large works this plan of mortar-making is very commonly adopted; but as yet we have nothing that I know of for machine-mixing the mortar which is suitable for small works, or applicable in the case of a confined city site. The ordinary system of "larrying" together the lime and sand mixes them, but very imperfectly, and the man's strength is very wastefully applied. If we can give him some simple mill, with a handle to turn, he will do twice as much work in a given time, and produce a much better material. I do not intend here to describe such a mixer as a pugmill would be, for I have seen mortar made in a pugmill which was very indifferently mixed. What we want is a grinding and rubbing together of the ingredients, not a simple turning of them over. Now I have not as yet spoken of the lime and sand, which of course are of even greater importance than the mixing. To begin with the lime, avoiding all unnecessary chemistry. What we want in mortar is that it should set well, and I find that amongst the workmen themselves there is a great deal of misunderstanding about this setting. Shortly after a brick has been bedded, we find the dry brick suck away from the mortar the greater portion of its moisture, upon which it stiffens, and becomes tolerably hard to the touch, and this is very frequently spoken of as setting. In much of the mortar we use now, this is all the setting we ever get. Except in the case of the grey limes and the lias, which set as silicates, we never get a real set due to the carbonisation of the hydrate, such as renders the Roman mortar so hard, except with the lapse of ages. I am certain that mortar with so much sand as we are now in the habit of using would never acquire any great degree of hardness from the decarbonisation of the lime. One thing I am quite sure of is this—that the chemical changes which may render our mortar of any value can only take place in the presence of a certain amount of moisture, and that the use of dry bricks, which drink up all the moisture, is fatal to good and sound work. "Wet bricks and stiff mortar," says the theorist. "Dry bricks, sloppy mortar, and plenty of grouting" (that most fatal practice), says the workman. Do what you will, I will defy any man to prevail upon the workmen to wet the bricks. They complain that wet bricks cut their hands all to pieces, and persist in using perfectly dry bricks, even in the hottest sun. "Grouting" is a sort of tradition with specification writers, and should never be permitted, as it is entirely a mistake. It washes the mortar away from the bricks, prevents the proper adhesion of the joints, and does all sorts of mischief. For all out of door work, we should use limes which contain such a proportion of clay as to render them dark in colour, such as the Medway, Sussex, or the lias limes. Almost every lime-burner of any importance can now furnish his customers with an analysis of his limes, and we should reject any which fall short of 10 or 12 per cent. of clay. The grey lime from some parts of the Medway, which contains as much as 18 per cent. of clay, makes capital mortar, and we all know the excellence of the lias lime, with about the same quantities of clay and iron. I do not wish my paper to read like a chemical lecture, but I am anxious to point out that the pure limes are absolutely valueless with the amount of sand we now use, and that to get good results we must choose a lime which, from the presence of natural silicates, can set or become permanently hard from the formation of hydrated silicates in lieu of any hardening due to the reconversion of the lime into a carbonate or the condition in which it was found. The hydrate of lime and sand, the condition in which mortar from pure lime goes into the works, is, and as far as we can judge ever remains, a dusty powder when dry. I have yet to speak of the sand, and I must not say more than a few words upon this subject. We are extremely well off for sand in the London district, and there should never be any cause of complaint in this respect. The best sand for use with our grey and chalk limes is a good sharp washed pit sand; I say pit sand, because we can never be sure of the river sand. Some of it contains so much dirt, coal dust, and worn sand, that we get much safer results with pit sand. As long as the pit sand is free from loamy particles it makes a better mortar to work with than the river sand, filled as it is with extraneous matter. One thing to be remembered is that the coarser and sharper the grain of the sand is the better will be the mortar, and this fact at once shows that to substitute for the sharp sand the scrapings and sweepings of our thoroughfares will not improve the quality of our London mortar.

I might say a great deal about rubbish in the form of stucco, stonework, iron, and slate; in fact, very few of our materials would escape any rubbish heap. But I must pass them over, and say a word or two about

WOODWORK.

Our carpenters' and joiners' work shows sad signs of deterioration both in materials, and, to some extent, in workmanship. I do not wish to imply that the carpenters of the present day are not much better supplied with mechanical appliances for carrying on their trade than were their brethren of a hundred years ago. This would be an absurd position to take up. But I do most fearlessly maintain that labour-saving machinery and the various contrivances for producing cheap joinery tend to promote "scamped" work. I think that most of you will also agree with me that the introduction of cheap foreign timber has done us more harm than good. However much we may sneer at the clumsiness and waste of material in old carpenters' work, there was a genuineness and a thoroughness about it which we miss entirely in modern woodwork. I would never (if I could afford it) allow either nails or glue to be used, for I am sure that there is nothing like the old-fashioned trenails for fastening and securing the different parts of the work; and what with the "priming" with which they are so industrious in smearing everything over "at the shop," and the shaky and green fir timber, and the glue and whiting in the shape of "stopping"—why, it is quite impossible to say what rubbish you may not be getting. You will think, perhaps, that it is all very well for me to exclaim against our modern work without pointing out any remedy, or you may think I wish to go back to Mediæval simplicity. I have really no such wish. I know it is quite useless to shut one's eyes against the fact that you can get a "handsome" moulded door made for about half a crown by a steam joiner, but I see no reason for associating bad materials with cheap workmanship, which, however, one only too frequently gets nowadays. To give an instance. In a large panelled gateway recently put up to form an entrance to the Kensington Gardens (every panel of which was glued up in two pieces, and which, to look at, was a nice piece of work, and admirably painted), there was, in less than three months, a fissure of about ¼in. wide in the centre of every panel, and this is no uncommon case. In fact, so fond are our builders getting of green wood that they actually have the work put together, primed and everything, before it comes into the country. In another case, in a large roof over some workshops at Leicester, all the struts had shrunk from their bearings, and this, mind, in the long way of the grain, a direction in which there should be scarcely any shrinkage. The only way I see out of the difficulty of bad woodwork is to discard paint, and trust to staining and varnish. We cannot get the good old oak of the times of our forefathers, but if we do not take some steps to defend ourselves we may shortly have to do without wood at all, and take to iron for everything, as the 'cute Boston men are doing. I may perhaps be told that bad materials and bad workmanship to a certain extent bring with them their own punishment. To bad bricks and mortar we undoubtedly owe that graceless sham known as stucco, which does for the bricklayer what "priming" does for the joiner, viz., temporarily conceals the shortcomings of his handiwork. How many a deluded victim has purchased a smart and substantial-looking place-brick villa, with the most attractive-looking internal fittings, only to find in the course of a few years that he will have to spend as much as the house cost him to put it into repair! I am convinced that so long as we sanction the use of rubbish as a building material, so long will men be found to supply us with it to any extent, and I hope that if I have occasionally put my points rather more forcibly than I am warranted in doing, you will excuse me, knowing that my sole motive is to expose a practice which has become only too prevalent, and which I have have termed "The Architectural Treatment of Rubbish."

A brief discussion ensued, in which Messrs. Douglass Mathews, C. H. F. Lewes, W. F. Potter, Phené Spiers, Rhodes, Clarkson, Quilter, and the President took part, and the thanks of the meeting were unanimously accorded to Mr. Redgrave for his paper.

An extension of the sea-wall at Exmouth is proposed by the Rolle Estate Trustees.

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page 6.*)

PLATE 17.—CONSTRUCTION OF A WREATH FOR STAIRS, HAVING SIX WINDERS TO LAND ON A LEVEL FLOOR—THE TANGENTS ON GROUND PLAN MAKE ACUTE AND OBTUSE ANGLES.

FIG. 1 shows the joint thrown from the centre. Cylinder twelve inches. Centre line of rail struck with a radius of seven inches. The narrow end of winders equals half a square step.

This drawing is almost a repetition of that already given on preceding plate.

The object is to show that a joint may be made on any part of circle without in any way affecting the appearance of the wreath. In some situations it is even preferable. Take, for example, stairs that have been badly planned; steps and risers standing in every position but the right—the whole misconstructed, and presenting difficulties which may be overcome by throwing the joint from the centre, in order to produce a proper wreath.

This drawing is simply intended to illustrate a method which may be successfully adopted when required.

Let us proceed with the mould and have a joint, say at C. This gives A, B, C, D for tangents, and D G as ordinate for upper part of wreath on landing. The ordinate for lower part is unknown until tangents are unfolded, as shown at Fig. 2.

Let the letters A, B, C, D on the right correspond with those on plan. Tangents are shown spread out on a board, as in laying out a string. The pitches of wreath being 2, 3, 4, 5. The height of lower wreath is given by P 2. The direction for its ordinate being P N. This transfer to Fig. 3, as shown on the extended tangent P B. Make right angle from P equal to radius on plan. Let tangents C B and B P correspond with those on plan.

Ordinate is now drawn through C, and seat made square with it. Height equals that at Fig. 2.

Remainder of drawing is in every particular precisely the same as that given on preceding plate.

Tangents on mould, as proved by 2, 3, 4, being equal to pitches having corresponding figures at Fig. 2.

Notice, that in obtaining bevel T for joint 4, the line marked "Height" and tangent 3, 4 are nearly parallel, but not quite so. The exact line could not well be shown without confusing drawing.

See to this, should it ever occur in actual practice; and remember that accuracy in obtaining and applying bevels is one of the most important points in hand-railing. Square sections show joints and application of bevels.

Fig. 4 exhibits mould for upper part of wreath Let tangents C, D, L equal C D G on plan. Extend D L. Then draw C R parallel with it. Let L K equal height K 4, Fig. 2. Join K R. This is the pitch.

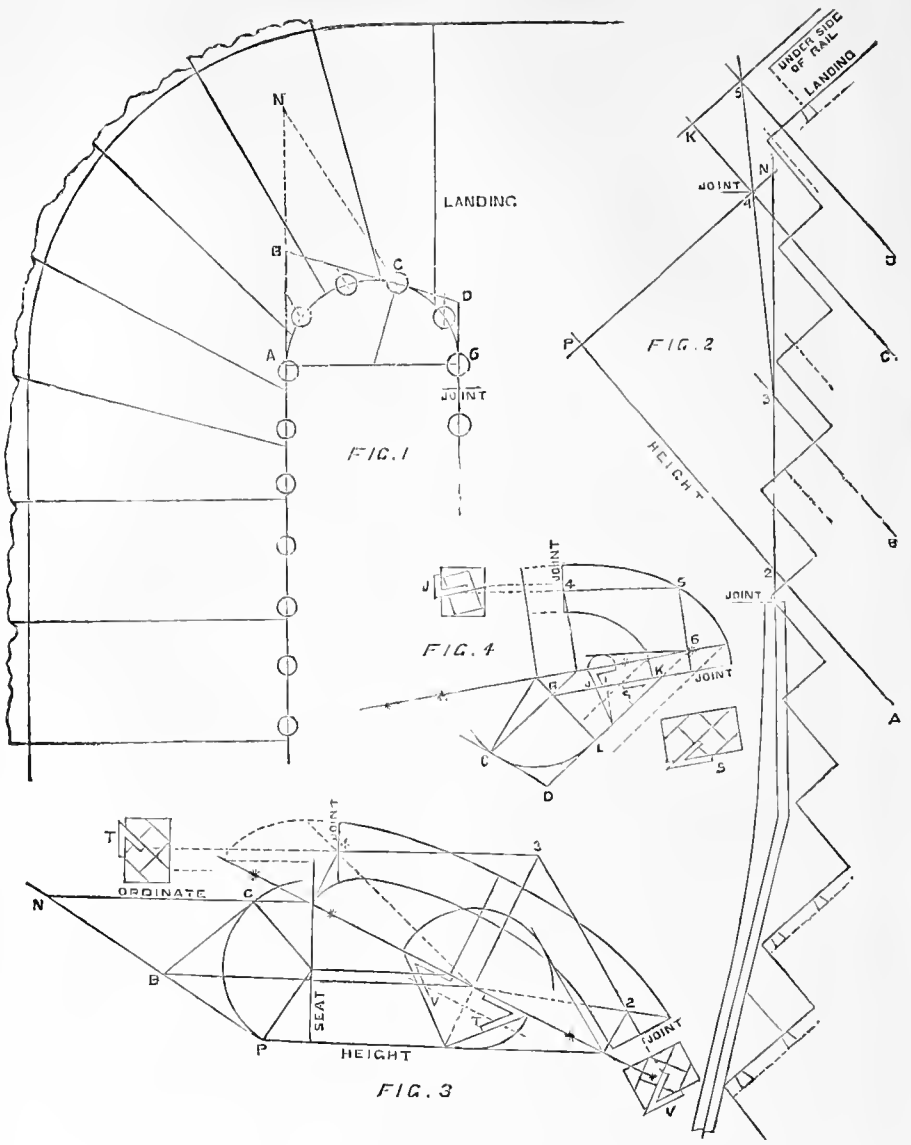
Let major axis of ellipse be drawn through the centre, and parallel with R K. This will be found more practical for construction of mould than having it on first pitch. Observe that the tangent 5, 6 on the mould when in position falls level, and is equal to L D; while that of 4, 5 stands on pitch; and, to be correct, must equal corresponding figures at Fig. 2. Have three or four inches of straight wood on wide end of mould, as shown.

The bevels and their application to joints have been already explained.

It may be noticed at Fig. 1, that A N being equal to P N on the right, gives ordinate N C. Then the lines drawn through centre of balusters on the left, cutting tangents, and parallel with ordinate, give a direction to transfer position of balusters from plan, to that of winders on right; showing their length, standing under pitches of wreath.

DUBLIN.—The Lord Lieutenant of Ireland visited the Royal Dublin Society's School of Art on Tuesday week, and inspected the designs, drawings, paintings, &c. of the pupils attached to the school. His Excellency was conducted over the building by Mr. Steele, who stated that the pupils of the Royal Dublin Society's School had gained a greater number of prizes than those of any other school in the empire with the exception of Kensington.

* This series of articles is a reproduction of ROBERT RIDDELL'S work on the subject, published in Philadelphia, and by Trubner and Co., London.



NEW ELEMENTS OF HAND-RAILING.—PLATE XVII.

HOTEL DE VILLE, TOURCOING.

OUR illustration is a front elevation of an Hotel de Ville for Tourcoing, France, for which the first prize was obtained in competition by M. Leon Rohard. The building is 26m. 10 wide by 47m. 35 deep. The belfry—an indispensable accompaniment to the public halls of the towns of the Northern Departments of France—is of wood, so constructed to suit the pockets of the inhabitants, according to the *Revue de l'Architecture*.

PHILIP HARDWICK, R.A., F.R.S.

ON the 28th December died Philip Hardwick, one of the few architects who have attained the rare honour of becoming a member of the Royal Academy. He was elected an Associate in 1839, and a full member a few years afterwards. From 1850 to 1861 he held the office of treasurer and trustee to that institution.

Mr. Hardwick was born in the parish of S. Marylebone in 1792. His father, also an architect, was a pupil of Sir William Chambers. Philip Hardwick attended Dr. Barrow's school in Soho-square, but while still quite young entered his father's office, and in 1808 became a student of the Royal Academy. In 1815 he visited the Continent, passing through Paris, then held by the allied armies. The Louvre, at that time the treasure-house of the spoils of European art, was at the time of his visit guarded by Prussian and English soldiers. The coincidence between the accompanying events of the opening and close of his professional career is noteworthy. Spending three years in France and Italy, he returned to England in 1818 and commenced practice. His earliest works of importance were the buildings for the S. Katherine's Dock Company. He was for twenty years architect to the Bridewell and Bethlehem Hospitals, but in 1836 was obliged to resign that appointment on account of the multitude of his engagements. He also held the office of architect to the Goldsmiths' Company, for whom he designed their new hall—a worthy specimen of his great abilities, and his most successful work. Among his other public works are the entrance-gateway to the London and North-Western Railway, in Euston-square, the Euston and Victoria Hotels, the Globe Insurance Office, and many others. He was a Fellow of the Royal Society and of the Royal Institute of British Architects, of which he was one of the founders. He received the gold medal of the Institute and a similar honour from the Commissioners of the Paris Exhibition of 1855.

Mr. Hardwick's designs were mostly in the Italian style. He suffered during the last twenty years from the effects of a severe illness, which compelled him to abandon his practice as an architect to his son, Mr. Philip C. Hardwick, in in the year 1842, when he was engaged on the designs for the new hall at Lincoln's Inn, which was opened by the Queen in 1845. He continued, however, for many years to take to such practice as he could attend to in his own room, and, though with much bodily suffering, was unremitting in his attendance at committees and at the meetings of the Royal Academy, in whose proceedings he took a deep interest.

His death is a grief not only to those who were privileged to enjoy his intimate friendship, but to all his fellow architects, by whom he was most deservedly respected and esteemed for his professional ability, his high character, and his pleasant manner.

Furniture & Decoration.

ON THE APPLICATION OF COLOUR TO THE DECORATION OF CHURCHES.

By "An Experienced Workman."

IT may not be out of place here to say a few words on the application of colour to the decoration of churches. We are more particularly led to the consideration of this subject in consequence of the recent publication of a series of four letters "On Colour in Churches," by Mr. Edmund Sharpe, M.A., F.R.I.B.A., in which the writer endeavours to prove that colour is a positive evil, that it destroys all architectural beauty and obliterates all detail; that colour, instead of aiding and assisting the play of light and shade (as most of us have hitherto innocently believed), does in fact destroy it altogether; and in support of his position he instances first some coloured decoration on the boards and rafters of the triforium of the choir of Ely Cathedral, which, according to his description, is most certainly an abortion in colour decoration; and secondly, the church of S. Cross at Winchester, which as an example of church decoration (an art, according to Mr. Sharpe, lower than that of the sign-painter) is equally bad as the first example. Now this may be true enough as far as these two examples are concerned. We are not in a position to dispute it, inasmuch as we have not seen the works, and they possibly may be gross examples of the misuse of colour, of which there are unfortunately so many in this our day; but we do dispute both the premises and the conclusion derived therefrom. It does not follow that because one or even a hundred examples may be brought forward of its mistaken and ignorant application, that, therefore, colour should not be used in churches, or in aid of interior decorative architecture, and as the pamphlet named is being extensively advertised, and is, we think, calculated to do much harm, especially when we take into consideration the high authority from which it proceeds, we have felt ourselves bound to enter our protest against the doctrine taught therein. The question whether colour should or should not be used in churches is of great importance, in whatever light we view it. It is either a legitimate and pure means of beautifying the house set apart for the worship of God, or it is a desecration of the sacred edifice. That question is too wide and of too much importance to discuss in this paper, and in considering the matter here we would confine ourselves as far as we can to the question as it affects the development of form and the decoration of our places of worship, for in considering such a question we cannot confine it exclusively to this or that style of architecture—not to the cathedral or the conventicle—to this or that denomination. We must consider it simply on its own merits, as to whether colour should or should not be used to develope and assist the detail of ornamental forms.

Mr. Sharpe says, "If you wish to take all light and shade out of a moulded arch, you have only to paint it; all the glorious effects produced by a flood of sunshine on the rich series of mouldings that clothe and characterise our English cathedrals are utterly lost the moment they are painted. The delicate transitions from light to dark on a rounded projection, the sharp line of light carried along the bordering fillet, and the dark shadow by means of which the deep adjoining hollow throws the two former into high relief, are altogether lost in a painted arch." This conclusion, so dogmatically set forth, we utterly dissent from, as being contrary to fact, to experience, and to the unalterable laws of colour. If Mr. Sharpe means the paint he condemns to be gloss colour we agree with him, because glossy or varnished colour reflects the light both from hollow and round; but if he means his remarks to apply equally to flat or dead colours, then we are quite certain he is mistaken, for it is a fact beyond dispute that certain colours have an affinity for light—so much so, that when the light touches these colours they appear to advance and stand out prominently, no matter in what situation they are placed; while another class of colours appear to carry back or cause every member upon which they are placed to recede or retire. Does Mr. Sharpe mean to tell us that if the colours which advance are placed upon the projecting member of a moulded arch or any enriched surface, and the colours which recede are put into the hollows and interstices or sunk parts of the mouldings, that thus we produce only flatness, and neutralise the effect of light and shade? If he means to say this (and we confess we can come to no other conclusion according to the text), we must either conclude that Mr. Sharpe is one of those unfortunates who are partially colour-blind, or that he has been equally unfortunate in his experience. Let us take a simple illustration in proof of our position that colour not only beautifies but assists the development of form. We will take a marble figure and place it against a whitewashed wall or in a niche which is also white. Do we thus best display the beauties of sculptured form? Do we thus bring out the graceful undulations and curves of the figure? Do we thus produce harmony, or show out to the best advantage the exquisite outline of the figure, and do justice to the immortal genius of the artist? We answer No! a thousand times no! Precedent, practice, and even the commonest of common sense answers "No." Look around upon the earth, sea, and sky; what do we see? Not one uniform colour varied by light and shade alone. Not sameness, not uniformity; not black, nor green, nor white, nor red, nor purple, but a beautiful combination of harmony pervades all Nature. No colour-blindness is observed in the works of the Divine Architect of the Universe: with Him all things are harmonious. Where can we find a better teacher? Where can better instructions be found? It may be argued that these buildings are the work of man; true, but they are all founded and modelled upon natural types. Our ornaments from the lotus, the acanthus, the vine, and the ivy. The Gothic arch is but the adaptation of the intertwined branches of the forest trees, which nature has interlaced and thus formed a model for man to copy. The rafters of the church roof and the intermediate spaces only represent the sky as seen through the branches of the trees. Do we build? We may yet go back with advantage to the bee and the ant. Do we wish to see how the most opposite and the most brilliant colours may be blended together so as to produce the most perfect harmony, and yet bring out the minutest detail? We must study the tail of the peacock, the plumage of the thousand and one birds of Paradise, and the wings of insects. The exquisite harmony which pervades all these, one colour contrasting and bringing out and purifying the other (for there can be no beauty without purity), all these go to prove that sameness is not, and cannot, be beauty. That paint, which means colour, according to Mr. Sharpe, destroys all the beauty of architectural form, is a mistake; for if we paint a cove, or the hollow of a series of mouldings of an arch or a cornice, with a colour which retires, and then paint the round beads or fillets, or other projecting members, with white or cream colour, or any advancing colour, we thereby not only increase the apparent depth and projection of each individual member, but we also assist the production of light and shade; all the delicate gradations of shadow are still there just as effective as if the whole of the members were white, but the colour intensifies them, for it is indisputable that gradations of shade are visible upon all colours; even black, if polished, will show, when the light strikes on rounded mouldings or ornament, an intensely bright line of white light, and even if it be dead black, totally without gloss, the gradations of light and shade will be distinctly seen upon it. We can well understand that if these colours are placed in the wrong positions, the advancing colour into the sunk parts of hollows and the retiring colour upon the projecting member, that the architectural features of the work will be destroyed. We daily see too many examples of this ignorant application of colour, but, as we have before said, if there are hundreds of these cases it does not necessarily follow that colour must not be used in churches. Another point for consideration is the fact that in the interior of churches the light which has to form the shadows upon the upper members of the arch, and on the roof, must of necessity come from below, which is not at all favourable to the development of form. Outside the building, on the contrary, we see every detail of the enrichment of tower, spire, and pinnacle, of door, of arch, and sculptured stone. Why do we see them so clearly? Simply because the light comes from above, uninterrupted, free to play upon and search out every coign of vantage on which to plant a brilliant fleck of light, and as a consequence sharpening the shadows so that every detail of ornament, and mould, and bead, and hollow stands out clear, sharp, and distinctly defined—every leaf, and flower, and joint, and projection—and it does not matter whether the stone be hoary with age or just fresh from the mason's chisel, the effect is the same. There is no colour required here to bring out detail; nature supplies the chromatic equivalents required to produce perfect harmony. Looking upon our grand old ecclesiastical buildings in this light, the eye and mind are alike satisfied, and are never wearied; but when we look upon the interior the condition and circumstances of light and shade are essentially different. Instead of the light falling in a flood of sunshine upon every moulded arch, and groin, and boss of our English cathedrals (as Mr. Sharpe beautifully expresses it), we find that in numberless instances the sunshine never touches them, only by reflection, by reason of the position of most of the window openings, and consequently the light which best defines the true form of the mould or ornament is absent. Bright sunshiny days are the exception in England, and with regard to the roofs of our cathedrals, how are we to get the flood of sunshine upon them? What are we to do for delicate gradations of light and shade upon those dull days, of which we have so many, when all is shade and gloom? Under these circumstances, without colour a church is of all places the most miserable-looking. It is not many years ago since we began as a people to emerge from the stupidity and barbarousness of the Puritan idea of art, when everything of beauty was considered a delusion and a snare—when colour, and ornament, and the beautiful symbolism of the Christian faith were banished from our churches, and the reign of whitewash commenced and reigned paramount. Does Mr. Sharpe wish us to return to the purity of whitewash? We should be loth to think so. We will go with him so far as to say that we would rather see bare and naked walls than colour misapplied, either in churches or elsewhere; but if colour and ornament be used with knowledge, judgment, and taste, and with due regard to its purpose and situation, we cannot conceive how a mind capable of appreciating the beauties of art and nature can object to the use of colour in a building which would otherwise be cold-looking, comfortless, and barn-like in its plainness, and in some cases particularly ugly. How many churches there are which, either from want of funds or from design, are left with the walls merely plastered, and without moulding to arch or window, with plain chamfered edges to the arches and splayed window openings. We should be glad to know how Mr. Sharpe would treat such interiors: would he leave them in their primitive state of nakedness, or would he improvise some decoration which would dispense with the aid of colour? If ever he does we should be glad to

see it. In the meantime we have a simple and lasting faith in the effect and influence of colour in its application to the decoration of the house of God. It the first place, because by striving to make His house as beautiful as our puny efforts can make it we thereby show our desire to honour Him. Secondly, because, however skilfully we may execute these works—however high, according to our limited knowledge and skill, we may rank our work—we know that it falls far short of the perfection of divine workmanship, as shown in the meanest and most insignificant insect or plant that exists, thus leading us to comparisons which tend to produce feelings of humility and devotion. We have no sympathy with the man who sees naught but evil in clothing the walls of the sacred edifice with the glorious effects to be gained by the proper use of colour and design; to such minds beauty, in whatever form it may appear, is but an emanation from the bottomless pit, and the beauty of colour is nothing less than the sign-manual of the Scarlet Woman of Babylon. It were easier to persuade ten thousand women that they were ugly than to persuade such a mind that colour may be used with propriety to beautify and adorn the house of God.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE first ordinary general meeting of this Institute since the Christmas holidays was held on Monday evening last, Mr. T. H. Wyatt, President, in the chair. The ordinary routine business having been transacted, Messrs. Lewis Solomon and T. Heygate Vernon were elected as Associates. The deaths were announced of Mr. Philip Hardwick, R.A., and Mr. Lewis Vulliamy.

Professor D. T. ANSTED, M.A., F.R.S., &c., &c., then read the following valuable paper

ON THE RELATIONS OF GEOLOGY TO ARCHITECTURE. —CONSIDERATIONS ON THE SELECTION OF BUILDING SITES.

IN a former communication I pointed out some of the facts relating to the application of geology to architecture, but I limited my remarks on that occasion to the subject of building material. I desire now without further preface to give some account of another relation between these two sciences, in the hope that I may be able to make a few suggestions of practical value, illustrating the importance of regarding the structure of the earth and the nature of the rocks when it is intended to make use of its surface as a basis of operations for important architectural constructions. If it is necessary to give illustrative proof of the value of such considerations, I cannot do better than remind you of those remarkable leaning towers in Pisa and Bologna that have sometimes puzzled travellers. I might also mention the Cathedral of Pisa, close to the leaning tower, as an instance of a noble specimen of mediæval architecture, in which there are no straight lines, no horizontal lines, and no vertical lines, owing to a neglect of knowledge as to the nature of the foundations on a shifting alluvial bottom. The extent to which these fine buildings are injured by this neglect, which may almost be said to have reduced noble specimens of art to mere curiosities and toys, is not a subject to which I mean to do more than allude. It is quite true that with modern appliances doubtful foundations may be converted into good ones, but while we appear to have a case of perfect success in this endeavour in the Houses of Parliament at Westminster, such appliances are not always enough to render a mass of alluvial sands and gravel resting on a lower mass also of alluvial origin fit to bear every kind of structure that may be put upon it.

The selection of a site is not often left to the architect, but it is certain that his work ought to be greatly influenced by it, and that his opinion should be sought and his advice duly weighed before the site is decided on, or at least before the nature of the construction is altogether fixed. But, if this is so, it is clear that his education should enable him to give such attention to this subject as to justify him in reporting on it in all its bearings and from every point of view, and should enable him to take into consideration both general and local conditions. Among them the geological conditions ought not to be forgotten, for they will infallibly influence the cost of building, the sanitary state of the future building, the methods available for improving what is unsatisfactory, and making the best use of natural capabilities, and according to the nature of the exposure they will affect even the permanence and durability of the building. I include in speaking of geological conditions some which perhaps more properly belong to physical geography, but there will be no need to draw a distinction between them on the present occasion.

I venture to say that the site and the natural conditions of the site should to some extent determine the style of the building, the plan of the various substructures, and the uses to which they may be applied. The material to be employed also requires to have reference to these points, while the contrivances for drainage and (except in large towns) the nature of the water supply must be modified to meet the local geological peculiarities of soil and rock. It will no doubt often happen that one or more of these are fixed beforehand, and are independent of the architect, but he should be able to adapt the rest so as to take the best advantage of circumstances. In no case can geological considerations be safely neglected. I propose in this memoir to point out and illustrate as far as may be some of the more important of these relations of science to art. There is a close relation between the science I represent and the art you practise. The pyramids of Egypt rising from the dead level of the Nile valley, and the temples of the same country, cut out of solid granite, exhibit adaptations of style to the material available and to the nature of the site based on the strictest and soundest judgment. Pyramids constructed in Egypt of brick or limestone are fit monuments for sandy plains, and seem to require a vast expanse to justify their severity and formality of outline, and their total unfitness for decoration of any kind. Rock temples, whether in Egypt or India, are immediate results from geological conditions. Impossible, except in similar positions, they possess, owing to their adaptation to local circumstances, a simple grandeur which contains the elements of the highest beauty.

To perceive the growth of architectural taste and the history of classical styles, we must refer to the geological conditions as well as the climate of the country where these styles originated. In Greece limestone of a creamy white or grey tint is the prevalent rock, and the limestone forms a plateau intersected by ravines reducing the surface to a number of flat-topped hills of no very great elevation separated by rocky valleys. Owing to the long-continued action of the weather, the limestone rock is much broken at the surface, and loose blocks of all sizes abound everywhere. In many places the whole of a hill-side is apparently made up of loose stones, naturally squared, and resembling a broken wall. Under such circumstances square forms, upright columns, and walls with rectangular openings, are inevitable. The earliest constructions in such a country must have been, as we find they were, caverns with square entrances, built of such stones as were lying about. After these came the Cyclopean structures, often described and very familiar to the architect and the archæologist. Out of such buildings grew the earliest forms of cultivated art and the elements of all the classical styles in architecture. In the Island of Ithaca the buildings known as the School of Homer and the Palace of Ulysses are especially illustrative and instructive. In Cephalonia are other examples, especially in the remains of ancient Samos, and both on the main land of Greece and in the Morea there are many similar instances. The towns were built for protection on the hill sides, and on the hill-top was the temple and the Acropolis. The valleys were cultivated, and for the most part, no doubt, the people lived in them, except when their safety was endangered by the approach of an enemy. The necessity of constructing the temples and great public buildings on elevated sites, where they would stand out boldly in a clear sky and be seen through an atmosphere of exceptional purity and dryness; the necessity also of using as material the rock under foot or the marble in adjacent quarries, the facility with which rock and marble could be chiselled into form, and perhaps some reasons connected with the history of the Greek people and the sources whence their inspiration was drawn, must have contributed largely to the formation of those classical styles prevalent wherever Greek civilisation penetrated. On the other hand, the cradle of Gothic art being in the North, in a colder climate and gloomier sky, and the development of that form of art being in countries where the surface consisted of wide river valleys or great forest-covered plains, where roofs were necessary and where elevation was needed to give effect to a building, the constructive material at hand consisting largely of wood, and the stones available including a great variety both of limestone and sandstone, the art of construction took a different direction and adapted itself to these very different conditions. The limestones of the North are very different from those of Greece, and exposed to the weather they change much more. Then natural conditions, added to the difference in race, and all mutually influencing each other, have produced the peculiarities of Gothic architecture as the natural conditions in Greece resulted in the adoption of classical styles. I will not detain you longer by preliminary remarks, except to remind you that Indian and Chinese architecture belong also to the country, the climate, and the people where they have originated, and that many singular varieties of style, especially those adopted in Spain and Portugal, as well as the various Italian schools of architecture, might without much difficulty be shown to be derived from or at least greatly affected by the soil and climate and the material at hand for building. In Art as in Nature there is a process of natural selection which is the real governing principal of all varieties; there is an incessant battle to determine what novelty shall take possession of the field, and to what extent the old and recognised species shall be superseded by some new modification. Every country and every century has its own special characteristic, but the groups are determined to a very great extent by the country rather than by the races. The *genius loci* manifestly affects the result.

The nature of the rock greatly influences the soil and subsoil, both of which are derived from the rock, either directly or indirectly, and must therefore have some effect on the buildings constructed on the surface. This is the case partly as involving the question of foundations, partly as being closely related to the methods of underdrainage generally required to secure the stability as well as the healthiness of the site. The architect is no doubt less dependent on the rock than the engineer, but he cannot safely neglect it. In my work on geology, published so long ago as 1842, I pointed out the importance of considerations of this kind, and although then a very young man, ventured to offer some practical suggestions in reference to it. Since that time I have had constant experience in these applications of geology—much more indeed in engineering than in architecture—and I have often had occasion to regret that some knowledge of rocks did not enter as a matter of necessity into the education of all architects and engineers.

Rocks may be conveniently grouped into several divisions so far as they affect towns, public buildings, and private residences, and it must be remembered that in most cases the architect has to deal, not so much with the rocks themselves as with the weathered and often rolled fragments derived from them. There is in most parts of England, and generally in Northern Europe, a superficial mass of moved material and soil masking the real underlying rock, and this is often so thick that digging for ordinary foundations does not get through it. Such material may, with due precaution, be safe enough, and it generally is; but there are cases where it certainly is not, and these should be understood. They can only be understood by one who has at least made himself acquainted with the first outlines of geology as regards the stratification, upheaval, and dislocation of rocks. In some countries, and in some parts of our own country, the rocks are at the surface, and then the whole question is easily decided; but when this is not the case, a knowledge concerning them can only be obtained by studying a little the science that deals with them.

Certain rocks, hard and compact in themselves, are so far fissured and broken as to allow water readily to pass through them. Parts of the millstone grit and of the new red sandstone among sandstones, the oolites and parts of the carboniferous limestone among limestones, are of this kind. They are rocks not in themselves absorbent, or partially so, but very permeable, owing to their mechanical state. On such rocks foundations are of course secure, and drainage good and easy. If such rocks can be reached, they are safe under ordinary circumstances so

long as they are horizontal; but if they are in strata inclining towards a valley, and the construction proposed is near or upon the slope, it is not seldom that additional drainage, and the weight of a building combined, may produce a slide, which will show itself in cracked walls and unsound foundations. Instances of such accidents are not rare. They may generally be foreseen, and to some extent provided against, by checking drainage between the strata, especially when the strata of stone are separated by films of clay, or by thin belts of sand. But they can only be known and prevented by the aid of that small amount of practical geology I desire to recommend.

Non-absorbent rocks, such as crystalline limestones and very compact grits and sandstones, are often so cracked and fissured as to let water drain into and amongst them, and in that case they are not often unhealthy. It is only when they have no outlet, so that the entering water stagnates in the rock till it evaporates, that they are likely to be injurious. I had an opportunity of observing a case in the island of Corfu some years since, in which a particular valley was entirely destitute of inhabitants, though it appeared in every way desirable, and at the time of my visit, in the spring months, was perfectly healthy. There was then a swampy bottom, but no miasma. I was informed by the people living near that a little later in the season the swamp dried up, and that soon afterwards miasma would begin to form, and would continue with a perfectly dry surface till the autumn rains set in. In this case the water could not run off underground, but though possible such conditions are exceptional. It is usual for hard limestones to be fissured and cavernous, and comparatively rare to find any large extent of such rock without a ready escape for water; but, on the other hand, compact sandstones, quartzites, schists, and other metamorphic rock and granites are very usually impermeable in every sense. The water is either retained on the surface, or runs off the surface, the mass of the rock—though not without receiving a small amount of water, which circulates at all depths through the agency of such fissures as exist—being practically unaffected by surface drainage. It will be evident that if the rocks, whether limestones or sandstones, or indeed of whatever nature, are not stratified, there will be nothing but fissures to carry off entering water, whereas in the case of stratified rocks much depends on the direction and amount of the inclination of the beds, and much also on the material occupying the spaces between strata. In these matters, which may be of real importance in planning and estimating the cost of a building, and also in determining the fitness of a site, the rocks must be consulted, and their language must be understood.

The case of clay greatly resembles that of compact hard rocks, which are non absorbent, except that certain clays can be depended on and certain others cannot. The clays bedded regularly, and alternating with other rocks, are simply impermeable. For certain purposes they afford excellent foundations, and may be safely trusted. The same is the case with shales, which are altered clays greatly indurated, and not working up easily into mud, but stratified either with other shales or with sandstones. It must, however, be remembered that shales very easily and rapidly weather on exposure to the air, and that what appears to be a hard rock only to be removed by blasting while in the earth, will often be reduced in a few winters into a mass of minute fragments, converted into mud, and washed away by the first shower.

But though much important and useful information may be gained by the practical man by studying the condition of the rocks, their nature, and their relative position, it is in reference to what are called superficial deposits that a familiarity with the history of deposits is most generally available.

Buildings are of course constructed on all kinds of sites; but for many reasons modern towns generally occupy valleys, and are thus distinctly contrasted with towns of other days, which were much more commonly, and for equal good reasons, perched on eminences. Valleys now traversed by rivers are far more convenient than plateaus, as more accessible both by land and water, and if less safe in a military sense than plains in some respects, they are much more so in others. But whatever the reason, it is a fact that all important and large cities are on or very near large rivers. Thus the condition of the rocks on the surface of valleys has important significance.

It may be assumed, in the present state of geological science, that all such open valleys as now form or contain the beds of rivers have been reduced to their present shape and have derived their present condition from the passage of water through them. The beds or bottoms of the valleys have been cut out by water, the transported material with which they are covered has been moved by water, the cliffs or slopes of the enclosing hills, at whatever distance, have been brought into their present state by weather action, and small as the stream may be that runs along a narrow channel in a winding course between these cliffs or slopes, it has been sufficient in the course of time to bring about the result we see before us. All that lies immediately beneath the surface in the valley often to a great depth consists of material removed very gradually by this water, even if below that there is yet another deposit of water-transported material, consisting of clay, stones, and sand, due perhaps to ancient glaciers, or left behind by icebergs that have floated over or have been stranded upon it when many fathoms below the sea level. Sometimes there are streams entering the main river from side valleys, and each of these again has formed its channel and left its mark. The more sluggish the main stream, and the further it is from its source, the greater in proportion is the effect of such feeders. When they are torrents they sweep all before them, and deposit large stones with smaller gravel, clay, and sand. When they have had a more even course, they deposit fewer large stones and more mud and sand.

From this account of the history of river deposits, given in a very few words and requiring to be varied in detail for every stream, without exception, you may understand the nature of the material that you have to deal with in preparing foundations for a large and massive construction in almost every part of England where such buildings are likely to be erected. The clay you find may be alluvial clay deposited by the stream, or it may be boulder clay left behind by ice. It may thin out at any point, and give place to gravel, to loose stones, or to fine sand. Beneath it may be a quicksand. A certain number of tons pressing on the square foot of surface may and will cause the clay to slip away from the sands, or the run of an open drain through such sands may, by removing them, remove all support. When in the bed of the main stream, there may be a very regular deposit of clay capable of supporting any weight that could be put upon it, but the intervention of one of the old and forgotten tributaries may have cut away part of this clay for an interval, or prevented its formation, and thus one part of a building may be on a good clay and another part on loose shifting sands.

(To be continued.)

"MADE GROUND."

MR. GILBERT R. REDGRAVE, in a paper read the other night before the Architectural Association, and the first portion of which appeared in the last number of the BUILDING NEWS, made a well-timed reference to the now only too-prevalent custom of erecting new buildings in the suburbs of London and other large towns on or in what is by no means euphoniously designated as "made ground." After the gravel or brick-earth found on the sites is all excavated, the pits are filled in with road scrapings and all kinds of decayed and decaying animal and vegetable matter. This rubbish, then, is the "made ground" on which hundreds upon hundreds of dwellings, from the small semi-detached cottage to the "stately family mansion," are yearly erected, regardless alike of sanitary and structural considerations. Dr. Stallard has emphatically protested against this practice, and notwithstanding that the correctness of his conclusions has been impugned by a member of his own profession—Dr. Trench—we believe, with Mr. Redgrave, that Dr. Stallard's view is the correct one. We are supported in this by the remarks made by Dr. Druitt—a physician of the first eminence—in the course of the discussion which took place at the Royal Institute of British Architects on Monday evening last, after the reading of Professor Ansted's paper on the selection of building sites. Dr. Druitt strongly condemned the practice of erecting buildings on "made ground," remarking that some of the most expensive districts of London were built upon rubbish heaps. If, he said, there be any truth in the fact that emanations from the soil would injuriously affect the health of the people living in the houses over it, it was incontestible that "made ground" was not suited for sites for dwelling-houses; and the fact of the practice of building on such rubbish having become so general during the last few years might be quite sufficient to account for one of the (even to medical men) most puzzling phenomena of the time—viz., the great increase of scarlatina of late, in spite of all the counteractive and preventive measures that have been adopted.

ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETIES.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—At the meeting on Wednesday evening, Mr. Syer Cuming in the chair, Mr. H. F. Holt read an admirable paper on the "Tames of Fairford." The object was to deal with the popular legends connected with the very fine windows in Fairford Church, by tracing the incidents of the contemporaneous history of this family, through whose munificence the windows were in all probability, placed there. The points demonstrated from a careful study of the wills of the chief members, and from other new sources, were that John Tame did not acquire the painted windows in 1492, or at any other time, by conquest, piracy, or purchase; that he did not found the church nor rebuild it; that he did not purchase the manor from Henry VII. in 1489; and that, in fact, he never had anything to do with the painted windows at all. Finally, that these windows were not ordered until after Midsummer of 1500, and were erected not later than 1505. The research displayed in Mr. Holt's paper was very remarkable, and the foregoing outline will suffice to show the energy he is still displaying in support of his original confident declaration, that these windows are due to the talent of Albert Dürer.

LIVERPOOL ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETY.—The seventh meeting of this session was held at the Royal Institution, on Wednesday evening, when a paper was read by Mr. W. Parslow "On Science in Architecture," Part II.

SOMERSETSHIRE ARCHÆOLOGICAL SOCIETY.—A conversazione of the members of this society was held at the Museum, Taunton, on Monday evening last. The papers read were:—"Charles II. in Somersetshire," by Mr. E. Chisholm-Batten, and "The Dialect of West Somerset," by the Rev. W. P. Williams.

THE SOCIETY OF BIBLICAL ARCHÆOLOGY.—A new society has been instituted under the designation of the Society of Biblical Archæology. It originated in a meeting held on Dec. 9th in the rooms of the Royal Society of Literature, the proposed objects being "the investigation of the Arts, Archæology, History, and Chronology of Ancient and Modern Assyria, Palestine, Egypt, Arabia, and other Biblical Lands, the promotion of the study of the antiquities of those countries, and the preservation of a continuous record of discoveries now or hereafter to be in progress." Dr. Birch, of the British Museum, who occupied the chair on that occasion, explained that the proposed society would clash with none of the philological or exploration associations now in existence, but would have a distinct purpose—to concentrate and utilise the scattered materials connected with the geography, arts, and antiquities of the lands of the Bible, and to systematise the progress of archæological research in England, America, and the Continent. The society has already received the promise of the support of the most eminent living Biblical investigators, and another meeting will shortly be summoned for its complete establishment.

WANDSWORTH COMMON.—After a long period of agitation the committee for the preservation of Wandsworth Common have succeeded in effecting an amicable arrangement with Lord Spencer, which will secure the common for public recreation and enjoyment. It is a matter of much congratulation to the neighbourhood that, instead of a protracted and costly litigation, a satisfactory settlement should have been achieved. To carry into effect this arrangement an Act will be submitted to Parliament next Session, which will convey Lord Spencer's estate and interest in Wandsworth Common to a body of conservators, who are to keep the common open and unenclosed.

Civil Engineering.

PROOF STRENGTH OF CHAINS.

UNLESS we regard the word chain to signify merely an assemblage of similar parts in which the total length bears a very large ratio to the lateral dimensions, the term suspension chain as applied to a bridge appears to be a misnomer. In all modern examples of suspension bridges the supporting chains consist either of numerous strands of wire twisted together so as to form a large wire rope, or of long bars united at their extremities by pins passing through eyes. The heads of the bar in which the eye-holes are made may be welded on the bar, or, by a new process, rolled at the same time with it. The latter is a very great improvement upon the former operation and should always be resorted to, notwithstanding the additional expense. It will be admitted that neither of these instances answer exactly to the popular idea of a chain, nor the signification which, constructively speaking, is generally attached to it. In a wide sense, anything that could assume the contour of the catenary curve would be a "catena" or chain, but as we are not at present inquiring into the derivation of the word, but into the practical value of the constructive agent it represents, we shall pass on to the more immediate subject of our article. Probably one of the most extensive and important uses to which chains are applied is in connection with shipping. Indeed, so well-known is the employment of iron in this capacity, that it is a very common occurrence to witness in the specification of a bridge, roof, or other engineering and architectural work, in which a large quantity of iron is wanted, the quality named as the "best cable iron." This naturally implies that the iron employed in the manufacture of cables is of a superior description, and when it is considered how many human lives, as well as much valuable property, is constantly depending upon the soundness and strength of chain cables, it is evident that they should be of the best material. Independently of these reasons, which are more than sufficient to render the above requirements indispensable, the nature of the strain to which chain cables are subjected is of a very trying description. It is far more severe than that which would result from the application of a weight merely requiring to be sustained at the end of the chain. The terrible and sudden jerks that cables are continually undergoing tax their strength and tenacity to the utmost. Engineers are well acquainted with the fact that a chain, or indeed any section of iron, will break with a much smaller weight when suddenly and violently applied than it would when the same weight is "laid on" gently.

Most of our readers are probably familiar with the appearance of a chain cable. The links are oval in shape, and a small cross piece, technically termed a stud, is inserted across them, in the direction of the minor axis or smaller diameter. This stud is of cast iron and its use is obvious. When the links are subjected to severe strain, they have manifestly a tendency to "draw," that is, to lengthen in the direction of the longer diameter, and to shorten in that of the shorter. The stud prevents this result and keeps the sides at their proper distance apart. The strain upon the link itself is tensile in character, but compressive upon the stud, which is thus made of cast iron, as the resistance of cast iron to compression, compared with that of wrought, is nearly double. On the other hand, the tensile strength of wrought iron is more than three times that of cast, so that each material is selected for the duty it can best fulfil. In previous articles relating to the strength of girders and various sections of iron, the influence of form or shape has been more than once conclusively shown to very considerably modify the actual resisting powers of the material. A very pertinent question in connection with the present instance arises. Does the conversion of the bar iron into the link of a chain increase or diminish the original strength of the metal? As a rule, iron is not improved, so far as either its tensile or compressive resistance is concerned, by any process of forging or welding. The science as well as the manipulative skill of the time have brought the two last mentioned operations to a degree of perfection that had not been attained to previously, but in spite of all the care and skill at our command, the "weld" can never be made so strong as the solid bar, or whatever other section of iron may be submitted to the process. At the same time, while it may be freely admitted that the "weld" is not equal in strength to the rest of the bar, it is a mistake to suppose that a "good weld" cannot be made. Some engineers and architects go so far as to set their face altogether against welds, but this is mere prejudice, and may very possibly arise from not possessing a thorough acquaintance with practical work and with the resources of a large and extensive "smithy." We have known instances in which a welded bar has been tested à l'outrance, and the solid bar has given way before the weld. This must be received as an exceptional case, but it nevertheless proves it is possible to effect this operation without deteriorating the resisting powers of the metal. To return to the question respecting the manner in which a bar of wrought iron is affected by its conversion into an oval-shaped link. Experience has shown, taking the average of superior and inferior qualities of iron, that a bar loses about a third of its ultimate strength by being converted into the link of a chain.

From what has been stated regarding the nature of the strains that chain cables have to undergo, and the serious liabilities contingent upon their parting, it will only be expected that the authorities should have taken some measures to ensure their being of sound and durable manufacture. Without for a moment underrating the claims of the mercantile department, the Royal Navy has to be first considered. The weight and size of the vessels, the complement they carry, and the large outlay incurred in their building and armament, demand that due care should be taken that they are not lost for the want of good cables. With the view of providing this requisite, the Government has adopted a test or proof-strain for all chain cables intended for vessels belonging to the Royal Navy. If we suppose a bar of a given sectional area bent into the form of a link, the proof-strain demanded by Government is equal to eleven and a half tons per square inch of the link. This test is calculated for one side of the link, so that the proof-strength of the whole link must be equal to the ultimate or tearing strain of the bar from which it is manufactured, supposing always the iron to be of superior quality. If it is not so, the link will not stand the test. This is a very severe test, but not more so than the nature of the case demands. In addition to the proof-strength of the chain being tested so far as regards the resistance to to a tearing or tensile strain, it is also submitted to ordeals of a more trying character, and which are more in consonance with the actual description of strain it will have to withstand when undergoing real work. Heavy and sudden blows are inflicted upon some of the links while they are under strain, in order to test the value of their resisting powers to shocks and violent vibrations. As in the course of their duty they will have to undergo repeated strains of this description, the precaution is not only justifiable but commendable. It may be urged that whatever may be the actual proof-strength of the iron it does not necessarily indicate the quality. A bar of iron may be sufficiently strong to withstand the proof-strain successfully, but its ultimate strength may be scarcely anything in excess. There would in such a case be nothing to spare, no margin of safety to rely upon supposing that on some occasion or other the strain in practice should exceed the proof-strength of the material. Some test therefore is evidently required respecting the quality of the iron. In fact, if the quality of the iron could be ascertained, à priori there would be no necessity for any tests whatever, as iron of such and such a quality will always bear a strain of a commensurate intensity. The Government authorities test the quality of the metal in the chain cables submitted to them for ascertaining the proof-strength by cutting out a link here and there from any part of the cable and breaking it. The character of the fracture, combined with the results of the other experiments, are sufficient and accurate indications of the quality of the iron, and the skill and care displayed in its manufacture and conversion into links. It cannot be too carefully borne in mind that the strength of a piece of iron is not an unequivocal test of its quality. A bar of iron that is not by any means homogeneous throughout its whole length may yet be able to resist the testing strain put upon it, simply because the strain may not affect its weakest part. It is uniformity of strength and of resistance that is wanted in all ironwork, more especially in such an example as a chain, in which the slightest weakness in one of the component parts will cause the failure of the whole. A single faulty link will cause the cable to part, the ship to be wrecked and the crew and passengers to be lost. It is scarcely possible that the proof-strength of a chain cable could be tested link by link, except so far as that the transmission of strain throughout the whole may be regarded as a valid criterion, but by cutting a few links indiscriminately a fair estimate may be unquestionably made of the soundness of the entire length. Should a single link prove defective while undergoing the ordeal, the whole chain is not condemned on that account, but a new link is substituted, and the cable submitted to a further test. As a rule manufacturers rarely send chain cables for testing that are below the standard, for the best of reasons: in the first place, it would be to no purpose, and in the second they would damage their own reputation for good work.

FLOATING DOCKS AT CARTAGENA AND AT FERROL.*

By Mr. GEORGE BANKS RENNIE, M. Inst. C.E.

AFTER touching upon the various modes formerly adopted of cleaning and repairing the bottoms of ships, the author referred more particularly to the wooden floating docks introduced by Mr. Gilbert in the United States of America, and to that made by him, in 1858, at Venice, for the Austrian Naval Arsenal of Pola, in which the two largest ships that had been docked were the *Kaiser*, of 3,225 tons, and the *Ferdinand Max*, ironclad, of 3,066 tons. The Messrs. Rennie having been called upon by the Spanish Government to make a proposition for furnishing a floating dock for Cartagena, capable of raising the class of ironclad ships then about to be added to the Spanish navy, having a weight of from 5,000 to 6,000 tons, which represented the *Numancia* and the *Vittoria* types, they proposed a dock somewhat similar to that constructed at Venice, but of iron instead of wood, with certain important modifications. In the wooden structure, in order to sink the dock sufficiently, it was not only necessary to allow water to run into the lower chambers, but water had to be forced into the top compartments at the sides, to overcome the buoyancy of the material; while in the iron structure provision had to be made to prevent the dock sinking when the lower chambers were filled with water. To accomplish this, the upper part of the side walls was divided into compartments, forming permanent air chambers or floats, of a capacity sufficient to maintain the decks of the side walls from 6ft. to 8ft. above the water level. The author laid stress on the importance of these for the safety of iron floating docks. As an instance of the success of the Cartagena dock, he mentioned that the *Nu-*

* Read before the Institution of Civil Engineers, January 10.

mancia, of 5,600 tons weight, had been supported on it for a period of eighty days. A list was then given of wood and iron floating docks which had come under the author's notice, all of which were of rectangular shaped sections, with the exception of the *Bermuda*, which was of a U section. This latter form required gates or caissons to close in the ends, which were not necessary in the rectangular section on account on the bottom and the keel of the ship being entirely raised out of the water. Less water had also to be discharged with the rectangular form, and the amount of pumping varied as the weight of the ship, whilst in the other, or U form, the smaller the ship the larger the volume of water to be discharged. The depth of the basement, or lifting chamber, of a floating dock like that at Cartagena mainly depended on the lifting power required. The thickness of the plates of the shell was ⅝in. and 1¼in. in the centre part. For such a vessel as the *Numancia*, weighing 5,600 tons, the strain was estimated to be 1·32 ton per square inch, and for a vessel weighing 20 tons per lineal foot 1·5 ton per square inch.

Of the different plans of conveying docks to their destination, it was remarked that—that of Pola was built at and towed from Venice, that of Havannah from New Orleans, that of Alexandria from France, and the *Bermuda* from the Thames; while those of Cartagena, Ferrol, &c., were sent out in pieces and erected at the respective ports.

The necessary repairs, painting, or cleaning, might be performed by careening, beaching where there was sufficient rise and fall of tide, raising the submerged part out of water by pontoons, or by floating the dock into a shallow basin; this latter plan being the one adopted at Cartagena.

The dock at Cartagena was 324ft. in length, 105ft. in breadth, and 48ft. in height outside; these dimensions of the dock at Ferrol were 350ft., 105ft., and 50ft. respectively. After giving a detailed account of the number of chambers into which the docks were divided, and the scantlings of the materials employed in their construction, the pumping machinery was described, and it was stated that it had been designed so as to be as much concentrated as possible, and thus be capable of being placed under the control of one man. The arrangement adopted was that of a pair of horizontal engines, working two pairs of lift pumps, to draw water from a common pipe, communicating with all the chambers. On the ends of these pipes were fixed the inlet sluices for filling the chambers, and on the sides smaller sluices and pipes in communication with each chamber, so that by opening all the sluices the chambers were filled, and on shutting the inlet sluices one or any number of chambers might be discharged. Thus the whole engine power might be employed in pumping out any one compartment, if it was found desirable to do so, in order to balance or level the deck. A detailed description of the engines, pumps, and sluices was then given.

The shallow basin, or dock receiver, with its three lines of ways, or slips, occupied the site of some old timber ponds. The basin was of a uniform depth of 16ft. 6in. from the top of the quay wall, and the depth of water was 12ft. 3in. The entrance was 126ft. wide. The basin was 382ft. long on the north side, and 345ft. on the south side. The end was curved, the chord of which was 200ft. From this end ran three lines of horizontal ways, or slips, radiating to a centre. Each was 725ft. long and 45ft. broad, and each was laid with four lines of timber ways, intended to receive vessels after they had been raised by the floating dock. It was estimated that six vessels might be building or be under repair at the same time, besides one on the floating dock. The foundations and masonry work were then described, and it was mentioned that the caisson for closing the entrance of the basin was similar to that made by the Messrs. Rennie for Pola.

After the basin and dock were completed water was let into the receiving basin, when the draught of water of the dock was found to be 4ft. 7in., giving a displacement of 4,400 tons as the weight of the dock complete. The dock was afterwards taken into the arsenal basin, and lifted vessels of various sizes—the iron-clad *Numancia* being the largest. The draught of water of the dock with the *Numancia* was found to be 11ft. 3in., the dimensions of the ship being—length between the perpendiculars, 316ft.; extreme beam, 57ft.; and displacement at the load draught, 7,420 tons.

The operation in docking this and other vessels had proved the dock to be in every way efficient, and from the arrangement of the distributing valves it could be managed with facility either in sinking or in lifting.

The *personnel* of the dock consisted of one chief-engineer, one master boiler-maker, and with other assistants amounted to eighteen men in all, and with this staff everything went on regularly and without trouble.

THE MADRAS IRRIGATION WORKS.

THE anicut across the Pennair near Cuddapah in the Madras Presidency is part of the last division of the Madras Irrigation and Canal Company's Works extending from Kurnooh to Cuddapah new nearly completed, and is close to the north-west line of railway. Since the works on this canal were resumed in 1868, the following work has been executed by the company's engineers on the 190 miles of canal:—Earthwork, including revetment and shingle, 7,237,900 cubic yards; masonry, including a large amount of cut stone in locks and sluices, 271,000 cubic yards. The work on the above anicut was commenced as soon as the designs received Government sanction, and the first well was sunk in February, 1869. This important work is half a mile in length, of which two-thirds are upon sand and one-third on rock foundation. The design where on rock is a simple wall; where on sand a sloping surface of masonry floored with cut stone, and resting upon four rows of brick wells filled with concrete, the toe of this masonry slope being protected by a dry rubble apron 105ft. in width. This work will be completed within four months, or two years from its commencement, the latter, however, only consisting of twelve working months.

Including the head works and locks, there are (according to *Engineering*) 38,000 cubic yards of masonry, including 1,150 brick wells, and 8,500 cubic yards of cut stone flooring, and 27,000 cubic yards of large boulders protect the foot of the work; these have been hauled three miles by bullock power.

During the last working season, from January to June, 1870, 22,000 cubic yards of masonry were built, which include 4,000 cubic yards of cut stone flooring and nearly all the cut stone required in the head works. There were also deposited in the rubble apron 14,000 cubic yards of large quartzite boulders. This rate of progress will compare with any work of the kind in India, as will also the cost and the quality of the work. The work has been carried out by the company's engineer, Mr. Higginson, C.E., and his assistants, with such labour as the district could provide. The extensive works of the railway company and the high rates that they pay, rendered it for some time difficult to obtain the bodies of men necessary; this was, however, overcome by having men trained on the completed portions of the company's works near Kurnooh.

BOOKS RECEIVED.

Church Design for Congregations: Its developments and possibilities. By James Cubitt, architect. (London: Smith, Elder & Co.) This very useful book was a short time back published in the BUILDING NEWS. The satisfaction expressed at its appearance in our pages by many readers augured well for its success in a separate form. The suggestions then offered to professional readers Mr. Cubitt now submits to the consideration of the general public, convinced that it is only with the intelligent concurrence of the outside world that architecture can in these times make any great movement. For the benefit of new readers who may not remember the work we will summarize its contents. Mr. Cubitt's "points" are, that more character and fitness are needed in our churches, and that neither of these are to be gained without discovering what the weak points of ordinary church-design really are. Having indicated numerous examples where either good architecture is sacrificed to convenience, or convenience to the orthodox church type of nave and aisles, the author directs attention to the improvements he would introduce. These are, briefly: plans with few columns, the adoption of wider naves and narrower aisles, the more frequent use of the dome; plans based on the circle, the octagon, and truncated ellipse: and improved gallery construction. If his arguments are not throughout well maintained it is not from the want of careful research and examination of ancient examples—the latter well thought out and adapted to meet the requirements of modern wants. If English architecture is indeed again to become what its name signifies it must do so by conforming, not to nineteenth century art-notions, but to its real wants, meeting them in the old art-spirit, and the more earnest workers in its cause like Mr. Cubitt the better.

Principles of Mechanism, by Robert Willis, M.A., F.R.S. (London: Longmans), is a thorough synopsis of the laws applying to combinations of machinery considered as governing the relations of motion. It is sure to become at once a standard work of its kind.

Handbook for Essex, Suffolk, Norfolk, and Cambridgeshire (John Murray).—Possibly continental complications have diverted the attention of some of Mr. Murray's "guides" to our own island; if so architectural and other tourists will set off against many disadvantages the opportune publication of this handbook. Embracing four counties, peculiarly rich in archæological associations, it deals well with its subject, and is almost as valuable as a reference for the architectural student as a handbook.

The British Almanac for 1871 needs only mention to secure its usual reception.

Irregularities and Diseases of the Teeth, by Henry Sewell (J. Churchill & Sons), is a reissue of papers on dental surgery, previously published in the *Lancet* and *British Journal of Science*.

The Young Mechanic, a Book for Boys, by the author of "The Lathe and its Uses," &c. (London: Trübner & Co.). This book cannot fail to be useful to boys of a mechanical turn. By the author of "The Lathe and its Uses," and "The Amateur Mechanic's Workshop" (both of which works originally appeared in the *English Mechanic and World of Science*, and were, we believe, very favourably received by many thousand readers of that journal), it is sure to be practical and therefore reliable. It is well illustrated and smartly bound.

Building Intelligence.

CHURCHES AND CHAPELS.

ALGIERS.—On the Feast of the Circumcision, the Bishop of Gibraltar consecrated the new church of the Holy Trinity, Algiers. The cost of the building is about £4,000. The style of architecture is Byzantine, with apsed chancel, western rose window, and gable belfry. The interior fittings are of oak, with open oak benches. The chancel and western windows are already provided with stained glass, and those of the nave will be contributed ere long.

EXETER CATHEDRAL.—The *Exeter Gazette* states that the monetary difficulty with respect to the commencement of the restoration of the cathedral of that city is at an end. The sum of £3,000 was wanted to make up the £15,000 required for the choir alone, and in consequence of that deficiency the chapter decided two or three weeks since to postpone the undertaking. Since then the Rev. Chancellor Hariogton has announced his intention of adding £3,000 to his previous gift of £1,000, in order that the restoration may be at once proceeded with, in accordance with Mr. Gilbert Scott's plan. A meeting of the chapter will be held shortly, and it is thought probable that the contract for the alteration and re-adornment of the choir will be signed forthwith. What the cost of the restoration of the whole cathedral will be has not transpired, but it is sure to exceed £50,000.

GREAT DODDINGTON.—The parish church of Great Doddington, Northampton, was reopened on S. John the Evangelist's Day, after restoration. The vicar, the Rev. M. W. Gregory, has acted as architect. The building was originally a large Norman church, with a large chancel full of small Norman windows with very deep splays. Some of these were wholly blocked up and lost until Mr. Gregory cleared away the accumulated whitewash and other obstructions; others were converted into decorated windows. Rows of what look like putlog holes occur both in the lower and upper stages of the walls. But on examination they are seen to go completely through the wall, and to be finished masonry throughout. Against the chancel arch on the south-west side is a wall-painting representing the Crucifixion, of good character, which Mr. Gregory has carefully preserved. The design for the roof of the chancel was supplied by Messrs. Law & Sons, of North-

ampton, but the design has not been carried out in its entirety. The whole of the work has been executed by Mr. Goodridge, builder, of Roade, under the supervision of the vicar. The cost of the chancel restoration has been about £400. The cost of the restoration of the nave is abont £600.

KIDMORE.—The internal decorations of the chancel of Kidmore Church, near Henley, have just received some most important additions. A new pavement has been laid down in the sacrarium, by Messrs. Minton, Taylor, & Co., of Stoke-upon-Trent, with an *Agnus Dei* introduced as a centre. The step in front of the altar is of Devonshire marble, as are also the columns in the arcade of the reredos. Trefoils of marble have also been inserted in the spandrels, with excellent effect. The architect was Mr. Arthur Billing, of Tooley-street, Southwark, and the builders, Messrs. Wheeler, Bros., of Reading.

LEAKE.—The chancel of the parish church of Leake is to be restored by Mr. Edward Browning, of Stamford, Messrs. Halliday & Cave, of Greetham being the builders. The works proposed consist of taking down and rebuilding the east wall and inserting a four-light geometric window ; new tracery to side windows ; an entirely new open-timbered roof, covered with lead, of the original pitch, as defined by the string-course on nave gable ; perforated stone parapets at sides and gable end ; a geometric and encaustic tile floor; new steps and seats ; windows reglazed with cathedral glass ; and thorough restoration of the whole of the walls and dressings. The amount of the contract is £1,250.

TORQUAY. — The parishioners of S. Mary Church, Torquay, have resolved (says a local paper) to remove the old church tower, and build a new one more in keeping with the church, which has been rebuilt lately. The tower is to be a memorial of the late Bishop. The subscriptions amount to £1,300, but £400 only is required to carry the tower as high as the ridge of the nave. We hope that this statement is not the precursor of a piece of Vandalism.

BUILDINGS.

BASFORD.—Some time ago it was resolved by the Basford Board of Guardians to erect a plain but substantial hospital, with all the most important modern comforts. The building, which was designed by Mr. Barber, architect, of Eastwood, is a plain edifice, two stories in height. It consists of brick with stone dressings, and is fitted up with everything which could possibly be suggested to conduce to the health of the patients. The building is now finished, with the exception of the fixing of the beds, and will be used for its purpose in a week or two. It will accommodate 131 beds at the least. The north end is devoted to males only, and consists of two bedrooms on each story, with day rooms adjoining capable of accommodating the number of persons required by the Poor Law Board. Communication between the hospital and the workhouse proper is obtained by a long passage or corridor. The main entrance opens to the centre of the building. The rooms on the ground floor of the centre are used for store-rooms, surgeons' and nurses' convenience. The upper story will be used solely for a lying-in ward, and will accommodate eight persons. The whole of the rooms are very lofty and well-ventilated. The outer walls are exceedingly thick, and have a space of 3in. between the inner and outer bricks. Besides the main building, which is to be used for general invalids, there are separate buildings for reception and fever wards and for other infectious diseases, all of which are provided with necessary comforts. Mr. Hopewell, of Basford, is the builder, Mr. Burton, of Basford, the painter, and Mr. Flewitt, of Nottingham, the plumber and gasfitter.

BIRKENHEAD.—Schools in connection with the Hamilton English Presbyterian Church in Laird-street, Birkenhead, have just been completed ; the accommodation of the whole, including two class rooms, is for 300 children, and the cost, exclusive of land, has been made under £750. There are two good playgrounds, and all conveniences attached ; the architect is Mr. James N. Crofts, of Liverpool, and the contractor Mr. D. Realdie, of that town.

STAMFORD HILL.—Mr. Samuel Morley, M.P., laid the memorial-stone of the new Congregational Church at Stamford Hill on Saturday week. The building was described and illustrated in the volume of the BUILDING NEWS just concluded.

UXBRIDGE UNION.—Extensive alterations and additions have been in progress at the above during the last few months, from the designs and under the superintendence of Mr. Charles J. Shoppee, of London, architect. The accommodation hitherto provided having been for some time past felt to be insufficient, the Guardians decided on erecting a new infirmary for males, in addition to altering the old infirmary (which formerly served for both sexes) for females. Mr. G. E. Kearley was the contractor for this portion of the works, together with the new boundary walls. A new ward for able-bodied men has also been erected, for which Mr. T. Taylor, of Uxbridge, was the contractor. Careful attention has been given to ventilation throughout the new buildings. Messrs. May were the contractors for the stoves and heating apparatus. Moule's earth-closet system has been adopted throughout. Mr. Collett was clerk of the works.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR. 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—H. M. C., C. B. A., W. B., R. E. B., J. N., J. B., S. & Co., P. & Son, S. & Son., Rev. E. K., W. A. P., J. H. T., T. B., Borough of Leicester, T. B. Hyam, S. Fisher, T. Burridge, J. C. J., W. E.

HY. WALKER.—The design will appear.
H. M. C.—The MS. returned by post.
C. S. S, J.—Sketch returned.
A YOUNG ARCHITECT.—Any elementary book on architecture, or state what you want in "Intercommunication" column.
THOS. COLE.—You can procure all the BUILDING NEWS sketches, or in the course of a few weeks you may purchase them in a volume.
HOLLEY & MILLER.—The engraving came to hand.
G. N. THOMAS.—A good sketch, but too late. The sketch returned.
E. WINTER.—Sketches returned—good, but too late.

INDEX TO VOL. XIX.—The index to the Nineteenth Volume of the BUILDING NEWS will be published with next week's number.

Correspondence.

CONCRETE BRICKS.

(*To the Editor of the* BUILDING NEWS.)

SIR,—Referring to the interesting paper of Mr. Gilbert R. Redgrave, read at the Architectural Association and partly reported in your last number, I may mention the manner in which a builder, who erected a good class of small houses for his own investment, prepared his concrete. He made thin mortar of grey lime, and laid it to the thickness of about 2in. in the bottom of his trench, then spread sufficient clean gravel ballast, to allow the ballast to appear about 1in. above the mortar, and would continue with alternate layers of mortar and ballast. Many years after his death, I had occasion to pull down and alter a portion of one of his houses, and found the concrete to be completely solid and hard, in fact an artificial rock. As to the bricks which Mr. Redgrave calls "patent," can he tell us why all such are made so large that they will not bond in with ordinary stocks ? I am convinced that their large size prevents their use for many purposes. I am using for some facing work a "patent" white glazed brick 9in. by 4½in. by 3 1-16in., and am compelled to build all the backing up slowly in cement. On another occasion I wished to use for internal facing the Burham Company's Gault clay bricks, but was reluctantly forced to alter my specification when I measured the samples and found them to be so thick as to spoil the bond of the other work. The same defect has caused me to reject a beautiful brick with an impressed pattern on its face. All the moulded, beaded, chamfered, and other bricks are so largely in excess of the thickness of an ordinary stock or malm facing brick, that I am sure they will never become popular until their size is so reduced that they can be readily worked.—I am, &c.

H. A. B.

ARCHITECTS AND SHARP BUILDERS' CLERKS.

SIR,—The remarks of your correspondent "Reader," which I have only just seen, are in one way very suggestive. They do not appear to need much special reply, as the writer in no way challenges my facts or propositions, but confines himself to a not over-refined ventilation of much accumulated spite against the higher ranks of the profession in general. His great point, however, seems to be that the public sanctions the practising of incompetent men by employing them freely.

Now this is exactly one of the great evils which I should like to see remedied. No one doubts that the public does and will employ incompetent men, because as a rule it finds them more accommodating as to matters both of taste and of finances. In the same way there can be no doubt that the public, the middle-class public of the towns more especially, would, if it could, allow its legal affairs to be misconducted by unauthorised attorneys who might offer a reduction of the orthodox six-and-eightpence ; and would hail with delight any medical man who would undertake to poison its families at half the professional rates.

These learned professions have long since found it necessary to protect the public and themselves by legal restrictions, and some system of examinations ; and it is hard to see why architects should not obtain some similar organisation. It would, I am confident, be an enormous benefit both to the public, the profession, and even to my friends the builders' clerks themselves, who, if so prompted by ambition, might with the help of careful study make a legitimate start in a profession which they are now obliged to enter, as it were, by the back door.

If only some man of good standing and energy could be found to take this matter up, I am sure it might soon be carried out, and that all parties concerned would soon be congratulating themselves on the result.—I am &c, J. B. F.

Intercommunication.

QUESTIONS.

[2087] ASPHALTE IN CHEAPSIDE.—What description of asphalte is Cheapside paved with—is it Seyssel and is there any hard material incorporated with it ? —Z.

[2088] PETERSBURG DEALS.—What is the reason that no real Petersburg deals can be obtained now? Much of the material supplied under that name by timber merchants is little better in appearance than white deal, and when stained looks abominable. It is high time this imposition was exposed.—Z.

[2089] QUANTITIES.—I would feel obliged to any of your readers for expressions of opinion on the vexed question of quantities, especially on the following points, viz :— 1. Is it a custom with many architects or surveyors to make a charge to each competing contractor on receiving a copy of the bill of quantities; and if so, how much ? 2. In the case of making a charge for each copy, should not the *balance only* of the 1½ per cent. commission be charged to the proprietor in the estimate? 3. Most of the architects of my acquaintance give copies of bills of quantities *free of charge*. But is not this rather unfair? Each of the competing contractors gets his value in the shape of a bill of quantities, and the chance of success in the competition for the contract; why should each competitor not pay at least a small amount on account of the percentage for taking out quantities ? Any account of the practice or custom of architects, especially in the provinces, in this matter will be thankfully received.—JUSTITIA.

[2090] TIN-LINED PIPES.—Is it a fact, as stated in your last number, p. 21, in a cutting from an American paper, that tin is more readily a tacked and dissolved by water than lead ? Or does some peculiarity in the chemical composition of the water of Boston give rise to the statement ?—F. O. H.

[2091] CHURCH SITTINGS.—Will some reader kindly inform me what amount of room is usually allowed for the sitting of each person in a church ?—T. W. C.

[2092] BOND IN BRICKWORK.—Will any subscriber kindly inform me by means of two small diagrams how old English bond is worked at the angles in 18in. walls ?—STUDENT.

[2093] STRIKING PORTIONS OF LARGE CIRCLES. Would any reader of "Intercommunication" kindly inform me of an expeditious way of striking a portion of a circle of any magnitude? I wish to describe a curve 1ft. in length, the said curve being a portion of a circle of one mile radius.—T. K.

[2094] MEASURING STRING-BOARDS TO STAIRS. Can any contributor to this column kindly tell me which is the best way to measure string-boards to stairs?—A JOINER'S APPRENTICE.

[2095] PREVENTING SOUND TRAVELLING FROM FLOOR TO FLOOR.—How can I best prevent the passage of sound from one floor to another otherwise than by using sawdust (which often rots the timber)? An answer would oblige—G. E. W.

[2096] CASTING LEAD PUMP BARRELS.—Will some practical plumber inform me how lead pump barrels are cast or moulded, and the square cistern heads and spouts, *i.e.*, what is the core of the barrel composed of? If, as it seems to me, it is a solid iron core the lead will shrink on cooling, and it must consequently require considerable force to draw the core from the barrel.—A THREE BRANCH HAND.

STAINED GLASS.

MELTON MOWBRAY.—A stained glass window will shortly be placed in Melton Mowbray Church, by Mrs. Frewen, of Brickwall, Essex, in memory of her late husband. The window will be made by Mr. Wailes, of Newcastle-on-Tyne. The subject will be "Moses Lifting up the Serpent in the Wilderness."

STATUES, MEMORIALS, ETC.

BISHOP'S LYDEARD.—The committee and members of the Somersetshire Archæological Society are about to erect a monumental brass in the chancel of Bishop's Lydeard Church to the memory of the late Rev. Francis Warre, vicar of that parish, and for many years secretary of the society.

Our Office Table.

LECTURES ON ARCHITECTURE AT THE ROYAL ACADEMY.—In consequence of the illness of Mr. G. G. Scott, R.A., the usual course of lectures on architecture at the Royal Academy, as announced, will not be given this session. In place of such series, Mr. E. M. Barry, R.A., will deliver two lectures on the subject; Dr. Meryon, one lecture on Beauty, and Professor Tyndall one lecture, the subject of which is not yet announced. It is also reported that Mr. Street, A.R.A., is engaged to give a lecture or lectures.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.—At the next meeting, which will take place on Monday evening, the 16th inst., a paper will be read "On the New Buildings for the St. Thomas's Hospital," by Mr. Henry Currey, the architect of the buildings.

THE FROST IN BATH.—During the frost, the good people of Bath, that city of crescents, were (says the *Globe*) subjected to an unusual annoyance. Although they live above an inexhaustible reservoir of boiling water, they could get no supply of cold, for the company's pipes were frozen. This happened everywhere; but luckless Bath had its gas frozen also. The theory is that the salts, which give the Bath water its salutary qualities, as indicated by the epigram on the monument in Bath Abbey—

> Here storied urn and animated bust
> Shew how Bath waters serve to lay the dust—

got somehow or other crystallised in the gas pipes during the intense frost. Whatever the cause, there is no doubt as the effect. Bath, which when lighted up at night is one of the most beautiful cities in Europe, rising terrace above terrace and crescent above crescent, has been in a state of Cimmerian darkness.

ANOTHER LANDSLIP.—A landslip occurred at Mevagissey, on Tuesday week, when a mass of rock, estimated at from 500 to 700 tons in weight, forming a portion of the road to the look-out station, fell to a depth of 50ft. into the ship-building yard of Mr. W. D. Lelean. Fortunately all the workmen were away at breakfast at the time of the occurrence.

DEATH OF MR. ALEX. MUNRO.—This well-known Scotch artist died at Cannes on New-Year's Day. Mr. Munro, a native of Inverness, was about forty-five years of age. His genius was early noticed by local friends, by whom he was introduced to the late Duchess of Sutherland, and through her recommendation he obtained employment for a short time from Sir C. Barry in carving some of the works on Westminster Palace. He soon became famous for groups of children and medallion portraits. One of the best known of his productions was the group from Dante of Paulo and Francesca, which was exhibited in 1851, and afterwards put in marble for Mr. Gladstone. His statue of Watt at Birmingham is a very fine work; also his bust of Sir W. Armstrong, his statue in Westminster Palace of Queen Mary, &c. Several years ago, Mr. Munro fell into very bad health, and found it necessary to live chiefly in the climate of Cannes, where he built himself a handsome house and studio. Whilst there, he executed busts of the Marquis of Dalhousie, the Grand-Duchess Constantine, and other visitors. His latest work was modelling a bust of his father-in-law, Mr. Carruthers of the *Inverness Courier*, intended as part of a semi-public testimonial about to be presented by some of that journalist's friends.

THE NEW LAW COURTS.—A deputation of London builders, consisting of Messrs. H. Lee, Plucknett, Hannen, Johnson, Trollope, and T. Lucas, have waited by appointment on Mr. Ayrton, at the Office of Works, in reference to the proposed conditions of contract, which had been objected to. These were generally modified, but on the principal supposed points of difference it appeared that the Commissioner and the builders were already quite agreed in substance, and the only question was whether the wording of the conditions carried out the intentions of the Commissioner and the builders. The legal adviser of the builders and the legal adviser of the Commissioner appeared not to coincide on the legal phraseology necessary, and it was left to these gentlemen to confer further together. The deputation expressed their thanks to the Commissioner for his patience and courtesy, and withdrew. The points of difference being reduced almost to a question of words, it may reasonably be presumed that no long time will elapse before the tenders are opened and the works so long delayed are at length allowed to proceed.

RAILWAY PASSENGERS.—There are sixteen railways in Great Britain each of which carried more than 5,000,000 of passengers in the year 1869. The Manchester, Sheffield, and Lincolnshire line carried 6,991,371; the North British, 8,507,171; the Great Northern, 8,733,764; the Caledonian, 9,226,684; the North-Eastern, 11,944,315; the Great Eastern, 13,008,907; the South-Western, 13,140,453; the Chatham, 13,963,882; the Midland, 15,567,454; the Brighton, 16,560,431; the South-Eastern, 19,157,205; the North London, 20,620,750; the Lancashire and Yorkshire, 22,643,002; the Great Western, 23,103,406; the London and North-Western, 28,758,886; and the Metropolitan (including the "District," St. John's Wood, and half the Hammersmith), no less than 36,893,791. These numbers are below the actual ones, as they do not include the owners of season or periodical tickets; the number of journeys taken by these persons is not known, but it has been estimated at about 350 each. The Great Eastern had in the year 1869 4,899 holders of such tickets; the Great Northern, 8,261; the Great Western, 4,300; the Lancashire and Yorkshire, 8,487; the London and North-Western, 11,299; the South-Western, 8,651; the Chatham, 8,568; the Sheffield, 1,814; the North-Eastern, 4,928; the Caledonian, 6,671; the North British, 6,918.

ASSOCIATED ARTS' INSTITUTE.—At the first meeting of this society since the Christmas recess, held on Saturday evening last, Mr. J. Hungerford Pollen, M.A., of the Kensington Museum, read an able paper on "Architectural Details applied to other uses," the first portion of which will be published in the BUILDING NEWS for next week. After the reading of the paper a discussion took place on the condition and prospects of the Institute, and whether these were susceptible of improvement by a removal to other quarters (University College was suggested), and changing the night of meeting from Saturday to some other more generally convenient evening. Eventually a committee was appointed to act in conjunction with the committee of the Institute in the consideration of these points, and in determining what further (if any) steps should be taken to increase the popularity and usefulness of the Institute.

WHITECHAPEL DWELLING-HOUSES.—The *Food Journal* is glad to perceive that Mr. Liddle, the medical officer of the Whitechapel Union, still continues his crusade against the nefarious dens that do duty for dwellings in that locality, and we cannot help feeling it a reproach to our authorities that it should be left so much to one energetic man to point out and make head against so monstrous an evil. In common with other medical officers of our populous towns, Mr. Liddle deprecates the system of tinkering that prevails, and is of opinion that nothing but the wholesale pulling down of these miserable blocks of buildings will be of the slightest use. Our Sanitary Acts are terribly defective, and although we have been promised over and over again that the whole subject should be thoroughly dealt with, nothing has yet been done that goes to the root of the evil. How long will our rulers shut their eyes to the irremediable mischief that, like leaven, daily increases amongst us, and will ere long burst its boundaries, and overflow all ranks of civilised society? A heavy retribution will some day be exacted of us, and we shall well deserve it; for in defiance of warning voices like those of Mr. Liddle, and Dr. Trench, of Liverpool, we are still utterly careless on some of the most important questions of the day—viz., the national health and morality.

THE INSTITUTION OF CIVIL ENGINEERS.—At the meeting of this society on Tuesday, the 10th inst., Mr. Cubitt, Vice-President, in the chair, five candidates were balloted for and declared to be duly elected, including two Members, viz.: Mr. James Edward Day, Melbourne, Australia; and Mr. Francis Jones, Ex. Eng. for Irrigation, Guzerat. Three gentlemen were elected Associates, viz.: Lieut.-Col. George Chesney, R.E., President of the (new) Indian Civil Engineering College; Mr. John William Inglis, Ex. Eng., P.W.D., British Burmah; and Mr. Charles Marshall Poole, Notting-hill. It was also announced that the Council had recently admitted the following candidates as Students of the Institution, viz.: Messrs. Henry Charles Baggallay, Crawford Peter Barlow, Fredk. Stuart Courtney, Thomas Duerdin, Charles Elwin, George Charles Gilmore, Arthur Charles Gotto, Richard Hamilton, William Horn, Joseph Tintorer, and Frederick Thomas Young. At the close of 1870 the numbers of the several classes belonging to the Institution were: 16 Honorary Members, 709 Members, 1,010 Associates, and 201 Students, together 1,936, as against 1,802 at the same date last year, showing an increase at the rate of 7½ per cent. in the twelve months.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.—At the eighteenth annual meeting of the London Association of Foremen Engineers, held at the City Terminus, Mr. J. Newton, of H. M.'s Mint, was unanimously, and for the thirteenth time, re-elected President of the Institution. The balance-sheet for the past half-year was of a most favourable character, and exhibited a sensible increase in each department. The society now possesses nearly £1,700 of funded money, and has 187 members on its books.

THE ANTIQUITIES OF IONA.—Mr. James Drummond, in a paper read by him to the Society of Antiquaries of Scotland, having referred to the state of the antiquities of Iona, has been replied to by the Duke of Argyll, who has for many years watched their condition and prevented important walls from falling. Parts of the Cathedral and S. Oran's Chapel have been strengthened, tombstones in the Reilaig Oran have been surrounded by an iron railing, and a number of the finest have been placed for safety inside S. Oran's Chapel and the ruins of the Nunnery, so that these fine specimens of Celtic art are well preserved, the people of Iona having long been in the habit of appropriating the old tombstones to cover their dead.

CIURNUM.—Mr. Clayton recently read before the Society of Antiquaries of Newcastle some "Notes of a Recent Excavation on the Roman Station of Ciurnum," in connection with which has been discovered a building with a frontage of 86ft., with three openings, and in the rear a range of five apartments, in one of which are the underground arched vault and steps discovered in the last century. Mr. Clayton considers the masonry just excavated to have been originally part of a forum.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—*Institution of Surveyors.*—"On the Proposal for making the Owners of Lands and Houses pay a Proportion of the Local Taxation." By Mr. Edmund Rushworth. 8 p.m.

TUESDAY.—*Institution of Civil Engineers.*—"On the Strength of Lock Gates." By Mr. W. R. Browne, Assoc. Inst. C.E. 8 p.m.

WEDNESDAY.—*Society of Arts.*—"How Meat is Preserved." By Richard Jones, Esq. (Professor Huxley in the chair). 8 p.m.

FRIDAY.—*Civil and Mechanical Engineers' Society.*—"Ought the Government to Appropriate the Railways?" By Mr. B. Haughton. 7 30 p.m.

SATURDAY.—*Associated Arts' Institute.*—Discussion introduced by Mr. H. C. Boyes. Thesis—"That Archæological Accuracy is neither Necessary nor Desirable in Art." 8 p.m.

Chips.

The national school at Whitwood Mere has just been enlarged. The works have been carried out from the design and under the superintendence of Mr. J. L. Parkin, architect, Castleford.

A new school is about to be erected at Capel Sion, near Aberystwyth, at the expense of Col. W. T. R. Powell, from designs prepared by Mr. G. A. Thomas, of Liverpool.

The Ham Hill masons have all been thrown out of work by the cold weather.

The bridge crossing the Tone at North Town, Taunton, is shortly to be widened, at an estimated cost of £350.

The Architectural Galleries in Conduit-street are now in process of re-decoration.

The collection of antiquities of the late Sir James Y. Simpson has been presented to the Society of Antiquaries of Scotland. The collection includes portions of sculptured slabs from Nineveh.

The old church of Charleywood, West Herts, in bad repair, and no longer equal to the wants of the parish, has been taken down, with the exception of the tower, and replaced by a larger edifice, from designs by Mr. G. E. Street, which was formally consecrated by the Bishop of Rochester on the 20th ult.

We understand that Mr. Robert W. Edis, F.S.A., is a candidate for the office of architect and surveyor to the Metropolitan School Board.

The designs and plans for the new promenade pier at Herne Bay are now on view at the Dolphin Hotel. The structure is to be composed entirely of iron, and the design is of a tasteful character. The estimated cost is £18,000.

Timber Trade Review.

PRICES, 10th January:—Quebec 1st quality bright pine, 18*l* to 19*l* 10*s* per P'tg. std. hund.; do. 2nd quality bright, 13*l* to 13*l* 10*s*; do., 3rd quality bright pine, 9*l* to 9*l* 10*s*.

Quebec floated pine 2nd quality, 12*l* 10*s* to 13*l*; Quebec mixed white spruce, 13*l* per 120 12ft. 3 × 9; 2nd do., 13*l*; St. John's, 12*l*; pitch pine planks, 12*l* to 12*l* 10*s*; best Archangel yellow, 11*l* to 13*l* 10*s*; Wyburg yellow, 9*l* to 10*l* 10*s*; Petersburg best whitewood, 9*l*.

Timber, per load of 50 cubic feet.—Norway balks, 30*s* to 35*s*; best Swedish, 52*s* 6*d* to 57*s* 6*d*; do. 2nd quality, 50*s*; yellow pine, 75*s* to 95*s*; red pine, building sizes, 60*s*; do. large square, 90*s*; ash, 70*s* to 85*s*; birch, fresh and large size, 95*s* to 105*s*; do. small, 60*s*; Quebec oak, 6*l* 5*s*; teak, 12*l* 10*s* to 13*l*; greenheart, 6*l* 10*s*; African oak, 5*l* 10*s* to 6*l*.

Petersburg lathwood, 5*l* to 5*l* 10*s* per cubic fathom; crown Memel pipe staves, 170*l* to 180*l* per mille; Bosnian staves, 32*l* 10*s*; Quebec pipe staves, 72*l* 10*s*; do. puncheon staves 21*l*.

Prepared flooring boards, 1in. thick, 6*s* 6*d* per square; do. 1in., 10*s* 6*d* per square; do. matched flooring, 6*s* to 8*s* per square.

Christiana spars, 4in. to 6in. in diameter, 1*d* to 1½*d* per running foot.

Dantzig deck deals, best quality, 25*s* to 26*s* per 40ft. 3in.; 2nd quality, 15*s* to 16*s* per do.

Honduras mahogany, 4½*d* to 5½*d* per foot; Mexican, 4½*d* to 5*d*; Tabasco, 4½*d* to 5½*d*; Cuba, 7*d* to 10*d*; Domingo, 7*d* to 10*d*; do. curls, 10*d* to 2*s*6*d*.

Cuba cedar, 6*d* to 7½*d* per foot; Honduras do., 4½*d* to 5½*d*; pencil cedar, 2*s* to 2*s* 6*d* per foot cube (ordinary quality); Florida do., 3*s* to 4*s* 6*d* per foot cube.

Walnut (Italian), 4½*d* to 5*d*; American large black walnut, 3*s* to 3*s* 6*d* per foot cube; do. inferior, 1*s* 10*d*.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

WHITCHURCH, Feb. 20.—For the erection of town-hall and markets in Whitchurch, Salop. Local Board Office Whitchurch, Salop.

WHARFDALE UNION, Feb. 9.—For plans, specifications, and estimates for the erection of a new workhouse, to accommodate 150 inmates, exclusive of vagrants, on ground situate at Newhall, near Otley. C. J. Newstead, clerk to the guardians, Board-room, Boroughgate, Otley.

MUNICIPALITY OF COLOMBO, Jan. 31.—For the preparation and supply of the smith and founder's work required for the new public markets and municipal offices at Colombo, Ceylon. S. Grenier, secretary, M.C., Colombo.

WAR DEPARTMENT CONTRACT, Feb 4.—For the necessary work and materials required in the performance of work and repairs, and supply of labour or materials separately, as required for the service of the War Department, to the buildings in the Permanent Barracks, camps, or property at Aldershott, and connected with the War Department property at or in the vicinity of Aldershott. Director of Contracts, War Office, Pall Mall.

HEREFORDSHIRE, Jan. 31.—For the erection of farmhouse at Hegdon Hill, near Bromyard, Herefordshire. Ernest A. Day, architect and surveyor, Foregate-street, Worcester.

WAR OFFICE CONTRACT FOR TIMBER, Feb. 4.—For the supply of dry ash plank, of the very best and toughest quality, thoroughly seasoned. Forms of tender may be obtained from the Director of Contracts, War Office, Pall Mall, London.

WALSOKEN, Jan. 20.—For the erection of farm buildings, a little below Osborne House; and for the erection of a pair of attached cottages at the Four Gowts, in the parish of Tydd St. Giles. W. Adams, architect and surveyor, Wisbech.

HEREFORD, Jan. 16.—For taking down and re-erecting two first class shops and dwellings, situate in Widemarsh-street, for Mr. C. Curtis. George Smith, architect, Ross.

LONDON AND BLACKWALL RAILWAY COMPANY, Jan. 24.—For brickwork, ironwork, earthwork, and other descriptions of work required for the construction of a part of the Millwall Extension Railway, about 650 yards long, near to the East Ferry-road and the side of the river Thames opposite to Greenwich Hospital. John F. Kennell, secretary, offices, London Terminus, Fenchurch-street, E.C.

LONDON, Jan. 20.—For alterations, &c., to the Old King John's Head, P.H., Mansfield-street, Haggerstone. Mr. Rogers, as above.

LONDON (St. Luke's Workhouse), Jan. 25.—For the erection of a kitchen and offices at the St. Luke's Workhouse, City-road. James W. Hill, Clerk to the Guardians, Clerk's Offices, Workhouse, Gray's-inn-road.

POPLAR, Jan. 26.—For the erection of stabling at Brunswick street, Poplar, for the London General Omnibus Company (Limited). A. G. Church, general manager and secretary.

PEPPARD SCHOOLS, &c., Jan. 21.—For the erection of a school and teachers' residence, at Rotherfield, Peppard, near Henley-on-Thames. Frederick Haslam, architects, Henley-on-Thames.

GREENWICH DISTRICT, Jan. 18.—For laying down tar pavement, Purbeck kerb, and for other works and materials required to make up the roads and footways of Caradoc-street, Braddyll-street, and William-street, Greenwich; and for laying down tooled York paving, Purbeck kerb, and other materials for making up the roads and footways of Florence-cottages, Florence-grove, Florence-street, and Florence-street east, St. Paul's, Deptford. E. W. James, clerk to the board.

IRELAND, Jan. 18.—For the construction of a transit shed in the Custom House Docks, for the Dublin Port and Docks Board. Drawings and specification can be seen, and a special form of tender obtained, at the office of the engineer, Bindon B. Stoney, North Wall, Dublin.

BANKRUPTS.

(TO SURRENDER IN LONDON).

Abraham Combes, Tyndale-place, Upper-street, Islington, builder, Jan. 24, at 12.

(TO SURRENDER IN THE COUNTRY).

William Clarkson, jun., Pudsey, stone merchant, Jan. 13, at Bradford.

PUBLIC EXAMINATION.—ACT, 1869.

Jan. 25. J. Stanley, Yarmouth, stonemason.

DIVIDEND MEETING.

Feb. 3, T. Rees, Glaish, Glamorganshire, builder.

SCOTCH SEQUESTRATIONS.

Peter Day, Aberdeen, builder, Jan. 21, at 11.—George Morrison, Bishopbriggs and Glasgow, builder, Jan. 19 at 2.

PARTNERSHIPS DISSOLVED.

G. & G. Sparrow, Nottingham, painters.—Bolt & Co., Newport, Mon., builders.—Baker & New, Bristol, engineers.—Hustler & Hirst, Frizinghall, near Bradford, joiners.—Day & Co., Wakefield, brick and tile manufacturers.—Rayner & Co., Huddersfield, boiler makers.—R. & R. Swarbrick, Lower Cunliffe, Lancashire, brick and tile manufacturers.—Whitaker & Gill, Bradford, painters.—Penston & Norton, Birmingham, builders.—Stevens & Jackson, Uxbridge, timber and slate merchants.—Beck & Candlish, Sheffield, engineers and tool makers.—Close & Goodbarne, Lincoln, builders.—Ash & Clayton, Sheffield, builders.

THE BUILDING NEWS.

LONDON, FRIDAY, JANUARY 20, 1871.

ALBERT DÜRER.

WE begin this week our promised series of the works of the great German artist. We wish the weather had been more propitious, as the want of sunlight has unavoidably interfered with the quite successful reproduction of the beautiful and delicate engraving with which we commence our illustrations. This print is said to be one of his earliest copper-plates, and is, we believe, the only one that he entirely copied from the work of other artists. It is the largest of the plates of the life of S. Mary. We feel sure that our readers will be pleased with so important a reproduction of the finest art, the value of which is inestimable. It is our intention, as far as possible, to give such illustrations as will best exhibit the various excellences of the master.

SCHOOLS AND PERIODS OF ART AT KENSINGTON.

WE are tempted back once more to these constantly-enriched and sometimes abused collections—a point on which it may be as well to say no more—by observing how vast is the wealth, in originals, copies, and models, which the public, and especially the artizan classes, neglect, while they throng around Mr. George Cruikshank's "Worship of Bacchus," which is not worth the wall-space on which it hangs, and which is simply calculated to deprave the popular taste, whatever it may do for the popular morals. The architectural and monumental specimens of that art which engaged the genius and divided the love of Giotto, Angiolo, and Raffaelle, producing the Greek temple, the Venetian palace, and the Gothic abbey-architecture, attracts a few students, but scarcely any general admirers, at South Kensington. Those beautiful mouldings, crockets, and corbel-heads might almost as well not be there. What proportion of visitors cares to bestow a sedulous day upon the history written for him between those walls? the gradations in decoration and construction; the decay of styles; the hiding—a sure sign of abasement—of the discharging arch above the Roman doorway with the barbarism of the sculptured architrave; the rise of the Pointed School, and the means of its destruction; the introduction of perishable materials into great building; and the decadence of the French and English forms, from the Cinque-Cento, which faced ponderous Gothic masses with Classic frivolities, and has culminated in the gilt-and-plaster glories of our gin-palaces and Jew clothier's shops. We believe, and are sorry to believe, that the educational influence of the Museum is infinitely small; that it is not cared for; and that amusement is the main object of the thousands who crowd its courts. What ideas do they bring away? Ask them about the naves of Beauvais and Cologne, or the spires of Salisbury and Strasburg, and will they have gained so much as a glimmer from the mind of the architects who reared those shrines of glory? How those wondrous visual effects were caused, when and why the round arch became pointed, and the ponderous solidity of the old Lombard wall became transfigured into airy frettings and frameworks of flying buttress and enchanted windows? Yet all this, and more, might they learn, for each of these subjects has its illustration. Yet it must be confessed that the Museum—apart from its class-room for professed pupils—is not a place where study of any kind has been facilitated by the arrangement of its treasures. At first it displayed an incoherent heap of scatterings from the Exhibition of 1851. Then, purchases were made from the famous and beautiful Bernal Cabinets. Afterwards it was attached to a national Science and Art Department. Next it fell into the hands of architects and amateurs, who would not or could not understand one another, but brought a number of miscellaneous casts for exhibition. To complete the aspect of a bazaar, patents and preserved provisions, toys and magic-lanterns were added. For "education" we had to read "recreation"; so that, speaking in a wide sense, the South Kensington Galleries are of no more intellectual value than—apart from its reading-room—the British Museum. The Vernon, Sheepshanks, and Turner pictures increased its fascinations; indeed, through this institution we have become possessed of foreign art antiquities, chiefly belonging to Italian, Gothic, and Renaissance, which might be envied by Paris itself; yet where are they? Where are the celebrated Soulages specimens? In a jumble. And in what sort of structure are they contained? In an edifice whereof it is hard to say whether it be intended for disfigured Venetian or debased Byzantine, with an interior of iron, brickwork, and tiles, and walls into which are built gates, reredos, chimneypieces, Della Robbia panels, and altarpieces, like mural tablets in a church; a roof supported by metal columns painted in porphyry colour; and modern picture-galleries that have nothing whatever to do with the legitimate purpose of the Museum, which was, so far as the fine arts and art workmanship are concerned, to throw a practical light upon a thousand years of human progress along the paths of civilisation. Having said thus much, to relieve a feeling forced upon every one who examines these collections and notes the impression apparently made by them upon the multitude, we have a more agreeable task in telling ourselves—as the catalogues do not tell us—of the opulence gathered under those vast spaces of glass and iron. Quadro-Cento and Quinque-Cento; gems from the great de Bruges and Soltikoff sales; mediæval *chefs d'œuvres* of the noblest rarity; generous loans of objects, priceless in value, from private proprietors, civic corporations, and the Crown itself; have amassed a collection claiming to be unique, though it is mixed up with an infinitude of rubbish, threatening to become still more repulsive when the dead-menageries of the British Museum are transferred from their natural gloom in Bloomsbury to these airy spaces, and lie—the lumber as they are—across the brilliant track by which fifteen centuries in the history of art are illuminated. Mistakes were often made, especially in the acceptance of loans and the purchases of curiosities. People were glad to be rid of Oriental commonplaces, Japanese armour, and Abyssinian relics, without actually selling them. Gallant officers deposited in the transparent caskets swords of Haran which they would have blushed to wear. Antique art was discovered to be more properly represented in private houses than has been thought; French and Flemish emblazoned MSS. came in by the hundredweight; and families uncounted were ambitious of lending a miniature. Upon the whole, however, the selections were judiciously made; and the really earnest visitor, to whom trouble is of little consequence, may pick his way from gold and silver, iron and brass, metal work of every period, to ivories that tell the entire tale of ivory-carving, from circular diptychs to seventeenth-century German quaintnesses: from Champlevé and Cloisonné, to the superb plaques painted at Limoges in the reigns from the Eleventh to the Thirteenth Louis, to the Persian. Henri Deux, Majolican, and Sèvres potteries, Roman and Venetian glass, and rings and gems, in thousands of which gleamed a spark of historical light. We linger over those sweet Sèvres vignettes, tinted on the *pate tendre*, which gave the village its secret and its renown; the *rose du Barry*, upon which fortunes were once squandered; the delicate Watteau snuffboxes, all delicacy; Palissy's humorous phantasms; even the light-tripping shepherdesses of Dresden. But they show us far more than ought to be seen. Each has its moral and social chronicle, even as have the works, various from age to age, of our English and the Italian gold and silversmiths. Is there no significance in the iron chair presented by the Emperor Rudolf II. to the free City of Augsburg, beyond the incomparable skill of its artificers? none in the circumstances of the time when it was wrought? none in the fact that it is now a mere relic in a foreign museum? That oval ivory basin, too, the tribute of a German Commonwealth to an usurper! Passing on, the faïence of the Umbrian mountain cities, though rarely noticed by visitors, reminds us of a once favourite and, at length, revived industry. We would particularly point out, however, to inquiring manufacturers and artizans, the steel in Ruker's chair, fabricated by a process which has hitherto perplexed the science of our day. This was the workmanship of Mediævalism. Between it and that of the Renaissance lies a deep, dark gulf, but even amid its abysses glimmer signs of an art spirit which never was utterly dead—the barbaric silver-gilt D'Azeglio ewer and basins, embossed as by Gothic hands, some grotesque enamels and specimens of pottery in the Della Robbia style. Parallel with these illustrations, subjects for study not less interesting are found in the copied examples of purely religious art. How far these may be interpreted as history may be shown by reference to a single, yet a most curious series of facts. It is commonly supposed that painters have always represented the Apostle S. Peter as holding the keys. Now in the earlier Pontifical coins even, a key was not visible. The first Pope who employed the effigy was John VIII. After him, the symbol disappeared for more than a century. Turning to pictures, on the same quest, the key is usually exhibited in the hands of the Saviour himself, seated on a rainbow at the doors of Heaven. It was not until the twelfth century that S. Peter was thus invested, but with one key only, holding two in the thirteenth. On the wooden door of S. Maria in Capitolio, Cologne, there is no key; on the mosaics of S. Maria in Trastevere, Rome, no key; on the Chasses des grandes reliqua, at Aix-la-Chapelle, no key. It was not until late in the fourteenth century, or little more than four hundred years ago, that the use of the sacred sign became general. But the act of giving the keys was adopted by artists at an earlier date. It is traceable in manuscripts of the eleventh and twelfth centuries, though the double emblem was introduced considerably later, one half being of gold, the other of silver or iron: and, ultimately the number rose to three. Instances may be adduced placing further back the introduction of these symbols, as in the Lateran mosaics; but in every case so many restorations and alterations have obliterated the original that, for purposes of archæology, these mosaics are, for the most part, worthless. Thus art goes far to prove what is history, and what is not; even when art, without this object, was rising in her triumph and her beauty over the glowing Italian land. So with architecture. The great legends of the world are written in the Egyptian, Greek, Lombard, Moresque, and Northern Pointed style, and in others less pure—called the Roman, early Byzantine, Venetian, Gothic, and Cinque-Cento. From the primeval type, "the Greek hut" supported by wooden posts, to the Athenian temples—luxuries of loveliness; from the preponderating masses of the Egyptian to the aërial and aurora-coloured domes of the Saracen; from the Doric, which was hewn, to the light Ionian, which was chiselled; from the Choragic monument of Lysicrates—exquisitely modelled, yet rarely glanced at in

the South Kensington Museum, albeit a work of matchless grace—to the swift descent from the S. Paul's of Christopher Wren to the S. George's and S. James's, of no matter whom in our own, is a long, and in many respects, a lamentable chronicle, reading itself aloud to all who will listen. We are growing better in this respect. As we no longer abandon furniture entirely to the upholsterer, so we have begun to think of climate and national habits, proprieties of form, the juxtaposition of colours, the employment of more various materials, and the application of ornament, even in our dwelling houses. In the treatment of some substances for art purposes, we are making an encouraging advance. As may be seen here, our work does not resemble the lace-like work of the 14th century any more than the rude sculpture of the Carlovingian age; but there are merits belonging to itself. Our wood-carving is far inferior, and depends for effect too frequently upon heavy coats of coarse varnish. This the most cursory comparison will demonstrate. We have, in metal work, nothing equal to the mediæval type, though the Hampton Court gates are admirable. Our enamels are chiefly, in style if not in subjects, copies from ancient schools, as the pastoral staves of Limerick, of William of Wykeham, and Fox, the S. Andrew's mace, and the Aumale cross. The old enamels were often almost lost in a superabundance of chased canopy work; then came the true pictorial enamel, cherished as an art by Ruker, whose name ranks with Cellini's, and is stamped on the sumptuous Julius Cæsar's shield, the Cowper salver, and many another work of immortal fame. As we have before said, much of the decadence is due to the losing of secrets. Thus, the fourteenth-century cup, adorned with transparent Cloisonné panels of coloured glass, exemplifies that which, once a familiar process, is now unknown, and the wavy lines and swelling contours in early glass cannot be more than spectrally imitated by us. Passing on—for these collections are inexhaustible—curious glimpses of long-ago life are caught among the Royal and the Devonshire gems, the cabinets of rings, the early Irish metal work, hieratically rich, and leaving the illuminated manuscripts, some busts are reached which sadly impair our historical ideals and cure us of dreams. The first, unquestionably a portrait, destroys at once the popular notion that Lorenzo de Medici was a personage of noble aspect. His face is ugly, hard, and mean, with the nose awry, giving two profiles, and expresses only shrewdness, cunning, and cruelty. Then there is a jasper jug, which Louis XVI. of France, by causing it to be mounted in the style of his era, claimed for that era, though it was wrought before Charlemagne reigned. This sort of imposition is by no means extinct. The French not long ago, when they had leisure for such tricks, medalled an artist for mimicking Gothic and Renaissance work, and daubing it over with sham ærugo. If for the single fact that it has already drawn serious attention to the question of art-ethics, we should be grateful to the originators of the South Kensington Museum. It must be long, of course, before the public at large appreciate it as more than a sparkling show. They will admire the American milking-machine, and turn their backs on the Libyan Sybil. They will mistake the painted Madonna from Munich either for the Queen, or for Gibson's Venus. We have heard one "well-informed" person instruct his friends that Trajan's column illustrated the siege of Sebastopol! Well, we must expect to pass through these purgatorial stages. The picture is too vast to be compassed by a glance. It takes a long time to read so large a book—and still longer to understand its contents, speaking as they do in languages so various..

The work of restoring the parish church of Chiltlehampton has been commenced. The contractor is Mr. J. Cook, builder, of Southmolton.

THEORY OF THE ARTS.

ART EDUCATION.

(*Continued from page 487.*)

A METHODICAL order of study, based on the relative importance of the knowledge of facts, as indicated in my last article, is what I propose to consider now, and I will do so in particular reference to the study of the principles and practice of architecture. From what has been said, there is a natural order, corresponding to the process of mental evolution, which must be followed in any course of instruction that promises results proportionate to the labour and mental exertion bestowed; and that it is abject folly to expect architects to be more than unthinking copyists, or engineers to be anything better than mechanical experts in applying formulæ, rules, and approximate tables, until the knowledge or science they apply in their vocations or arts has been acquired by a graduated process of thought, commencing from the simple, general, and useful, and proceeding to the complex and special in a logical order or method.

The ordinary course of study pursued by our practitioners of medicine and other physiologists, beginning with the organic or the study of living bodies, before they have made a sufficient preparatory study of chemistry or inorganic physics, has been commented on by more than one writer of science. A smattering of the dead languages is the only preparation many of our students for scientific professions receive. It is very much the same sort of education, though generally less methodic, our young artists and architects go through. The anterior ideas or phenomena, so to speak, of their art, are quite neglected or made to subserve studies of a more advanced and special character. Elaborate models, drawings, and works of art by the great masters are thrust before them long before they can really appreciate or judge the simplest technic merits of such works. Thus, the figure and the drawing of animal life and coloured studies often precedes any just conceptions of outline or form. It is true, in our modern schools of art, this defect has been in a great measure rectified by a more rational course; but even in these the grades are not always given, so that the mind and eye can feel interested or see the necessary transition from the first to the subsequent step; in short, they are not so arranged as to lead the mind from one kind of conception to another. The connection is wanting. We get, for instance, an abstract idea of a line or form before the eye has understood the tangible or simplest particulars of real objects—the faculty of abstraction or comparison is called into requisition before correct perception of quality. The knowledge derived from observation of simple facts and qualities is incomplete when combinations, and generalizations, and complicated theories are forced upon the attention long before the mind is prepared to receive them. In short, à priori principles are taught before the facts on which they are founded have been understood. In art, as in physics, such a course cannot be productive of progress. In an empirical and early age such a course was indeed followed; but we shall find, on close investigation, the principles were not the abstract laws laid down by a later and maturer age, but the mere embodiments or prescribed rules of a limited experience. Hence, à priori reason was insufficient to advance physical science beyond a certain point: in fact, only the most abstract and general truths were evolved with anything like precision under it.

Architecture is a special and complex art, made up of experimental knowledge of facts, organized knowledge or science, and applied knowledge. It is impossible to obtain a correct idea of architectural design, then, by a knowledge confined merely to studies of ancient buildings and art—the specific results of particular epochs or styles—even though such studies be extended to minute analyses and investigations of the special characteristics of each style or period. The most elaborate researches into such studies, though interesting, are about as useful to the student of progress as studies of ancient treatises on metaphysics or the physiological works of the twelfth and thirteenth centuries. They may interest, but cannot instruct, save, indeed, historically. Much as we admire the examples of Classic or Mediæval art, and point to them as models of contrivance and taste, as compared with the shortcomings of our own, we should far more advance the progress of architectural knowledge and taste by a systematic study of the sciences and arts allied to architecture, and a careful generalization of the elements of the most successful works, for their various uses, of our own day. The studies made during the last century by our material arts—the change in our wants and taste, make it impossible, if not absurd, to look back three hundred years for any information of value, except for ideas of the simplest and most abstract kind, and which should be learnt experimentally, not unthinkingly adopted. I know such a view will be thought dangerous, if not positively heretical, particularly at a time when we are deluged with books of ancient examples and reproductions of the same in bricks and mortar. The time and labour spent in some of these Herculean efforts is regretful to witness, except they be as records of a quickly-dying past.

But the fallacy of the old mode of procedure hardly needs further exposure. From what has been said a classification of the sciences is of the first importance in art education, the sciences being the necessary foundation to applied knowledge. Tabulating them we have two great classes:

1st. INORGANIC SCIENCE, including the most fundamental, general, and simple phenomena, and embracing abstract mathematics, mechanics, and chemistry.

2nd. ORGANIC SCIENCE, including special physiology, zoology, botany, &c.

From mathematical analysis, the first and most perfect of the fundamental sciences, being the most general, simple, and abstract, to the most special of the 2nd class, as physiology, the degree of speciality and complication is increasing. While the first is the most absolute and universal it does not possess the special and direct interest of the latter class of phenomena. It must be observed, also, the dependence of the phenomena of the different sciences increases in the above order; and that accordingly we find this to be also the order of their development or progress, as I have indicated before when speaking of the law of mental evolution. The necessary corollary of this is that the relative degrees of perfection or precision of the different sciences are determined. Thus, the ideas involved in mathematical propositions are necessarily the most exact and precise the mind can form, though the reader must not infer from this that the organic sciences are less precise or determinable in their results. The fact is, they being more complex and variable in their phenomena are dependent upon the anterior facts of inorganic science, and require greater time for development. Again, the order, as given, corresponds precisely with the degree of utility and importance of the facts involved; and it is in this respect that such a classification of knowledge is highly necessary in determining the relative values of ideas in the mind, and their relation to the different and various purposes and functions of human art. Hence the architect who has not prepared himself for his special labours by a preliminary study of the laws of matter and force, or the relations of magnitude and quantity, is utterly incompetent to deal with the materials and money at his command, and is wanting in the fundamental condition of his art.

Comte, in his "Philosophy of the Sciences," points out the absolute necessity of the sciences being learned in a natural order, before the Positive method or phase can be reached, not

only for this, but as a basis for a rational education and method. He also shows that some sciences are advanced more than others towards the Positive or permanent phase, while others are passing through the middle or transitory stage. Some even are still in the primitive or supernatural state. Thus, astronomy and other sciences founded on mathematical truths are in the positive condition; meteorology and physiology in the transitory state; while sociology and other kindred concrete sciences have barely advanced beyond the first. G. H. G.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

DR. G. G. ZERFFI delivered the twelfth lecture of his course on the above subject in the Lecture Theatre, South Kensington Museum, on Tuesday afternoon last. He commenced by entering into the relations the mythology of the Greeks had borne to their art, and gave a brief outline of what Greek mythology really was, with the view of showing that the study of these myths and legends would develope the faculties for producing original works of art, supplying the mind with bases to work upon. In comparing Indian, Egyptian, and Greek mythologies we were struck with their similarity, and it was impossible that this connection should be merely accidental. Mythology first used the imagination to typify the forces of nature by means of abstract signs, such as triangles and circles. This was the case in savage art, where geometrical figures were employed as symbols of divinities; later, however, the vegetable kingdom yielded these symbols. Certain trees and flowers became the representatives of the hidden, incomprehensible forces of nature. These were succeeded by animals. The animal, endowed with an unconscious vital energy, appeared to have some mystic power, and was considered specially adapted to guard the entrances to palaces or temples. Imaginary combinations of various animals were then made, which were symbols of the secret and terrible power of the gods. The less the sense of symmetry was cultivated in a people, the more frightful would be these combinations. The introduction of human figures as symbolic representations of the powers of nature was a progressive step in the development of mankind. The anthropomorphism which swayed the Greek mind soon taught this people to discard the fear of inanimate things felt by other nations. The cat or bull-headed divinities, the terror of the Indian or Egyptian, supplied the Greeks with motives for the ornamentation of chairs, metopes, &c., and endowed with an inborn gaiety they soon looked upon their own legends of the Gorgons and Græes as myths. In considering these legends, it was necessary to bear in mind that they all had some meaning, and were drawn from natural phenomena. The winged horse Pegasos, that sprang from the trunk of the monster Medusa, when she was slain by Perseus, and was tamed by a beautiful youth, Bellerophon, referred to the real subjection of the horse by man. The origin of music and poetry was typified in the legend which related that the daughters of King Pieros challenged the muses to try their power of song. Whilst the daughters of Pieros sang the air was darkened and the earth groaned, but to the voices of the Muses heaven and earth listened, the motion of the stars was arrested, and seas and rivers hearkened enchanted. Mount Helicon, the spot on which the concert took place, swelled with delight, till Neptune, alarmed at its increasing size, sent Pegasos to stay it. This was accomplished by a violent kick, but from the spot touched by the hoof of the animal the spring Hippokrene gushed forth, and whoever drank of its waters became inspired with the spirit of music and of song. The volcanic eruptions which, as the study of geology showed, must have been frequent near Cilicia, in Asia Minor, were represented by the monster Typhon, who was said to have been born there. He reached to the heavens, and his arms, which extended to the east and west, terminated in dragons; his eyes were of fire; when he spoke the foundations of the mountains trembled. He was finally conquered by Zeus, who confined him beneath Mount Etna, whence he vomited fire when enraged. Such monstrous creations as these had retained their hold on the Egyptian and Indian mind for ages and ages. Wherever this had been the case art had either become stationary, undeveloped, or unsymmetrical. The Greeks, however, soon broke the spell which fettered their intellectual appreciation of beauty, and the stiff, primitive forms of Assyria and Egypt gave way to well-proportioned human figures. Nature remained the basis of Greek art, but it was a nature refined and purified by intellect. About 900 B.C., the period at which Hesiod wrote his "Theogony," the forms of the divinities assumed symmetrical shapes. This poet, though not so powerful as Homer, described the divinities with much sweetness and grace. In his writings the mystic dreams of the Indian, the prejudices of the Egyptian slave to a hieratic system, or the fancies of the extravagant yet despotically ruled Persian, found no echo. His gods were men, men with divine thoughts and catholic hearts. He combined feelings with thoughts; the abstract ideas of the gods were used in concrete forms; the occult forces of nature were embodied in beautiful human beings, and thus monsters vanished and even the thunderbolts of Zeus served the purposes of symmetrical ornamentation. The human form became the fundamental principle of architecture with the Greek, the sublime object of his sculpture and the only theme of his poetry. To humanise everything; nature and the gods, was the historical mission of this nation. Having given in detail the genesis of the Greeks, Dr. Zerffi drew attention to the fact that Kronos, who was said to have devoured his children, and then given them back again, represented time, which consumed hours, days, weeks, months, and years, and yet continually brought new periods forth. The legends of Greek mythology (he continued) possessed an inexhaustible supply of motives for the sculptor, painter, and ornamental decorator. In illustration of this he related the story of Cupid and Psyche, and referred to the frescoes on the subject painted by Raffaelle to adorn the Farnesina palace at Rome. In these pictures the most charming allegory of Grecian lore was immortalised. This should encourage us to study Greek mythology diligently and systematically, as we should be able to draw thence many ideas for ornamentation. The earliest Greek works served to illustrate their legends, and in modern times Canova (whose exquisite group of Cupid and Psyche alone was sufficient to have rendered him immortal), Thorvaldsen, Rauch, Flaxman, Danneeker, and Schwanthaler had all availed themselves of the store laid up by them. It was not, however, to be thought for a moment that we were to *copy* the masters of Greece, but like the great artists mentioned we should read the legends and then tell them in our own words. In addition, the study of Greek mythology forced us into a closer study of nature, for their mythology simply represented nature dotted with imaginative poetry. To the question of the American poet, Holmes, who asked

> Why floats the amaranth in eternal bloom
> O'er Ilium's turrets and Achilles' tomb?
> Why lingers fancy, where the sunbeams smile
> On Circe's gardens, and Calypso's isle?
> Why follows memory to the gate of Troy
> Her plumed defender and his trembling boy?

we might answer, because in those Greek productions of art, poetry, and science, we met with the first fruits of man's creative power—well proportioned, symmetrically arranged, and full of action. Life with the Greek had been one continual festivity, during which his awakened consciousness had discovered nothing but beauty. He had worshipped his gods in singing to them joyous songs, in running and wrestling; for he had thought it his duty to develope the body and the intellect with which his divinities had endowed him. He had, therefore, either composed poetry or recited that of his gifted bards. He had rejoiced in athletic sports, which perfected the beauty of his harmoniously-constructed form. Everything both in art and science had been with him means for a grateful worship of his ever-smiling, ever-beauteous gods. He had not constructed his temples to exhibit his wealth; his temple had been a prayer in stone to his divinity. He had not ornamented for mere display; his reliefs, his sculptures, his frets or meanders, had been epic poems, lyric effusions, dramatic representations, in marble, stone, or terra-cotta, on his plates, chairs, the bodies of his vases, or on walls. The Greek had always been inspired by higher feelings. Art had not then been the handmaid of some political or theocratic despot, but had been practised, loved, and cherished; had been cultivated and fostered by the whole nation. Art with the Greeks had been the plastic language of ever-praying lips, hands, and minds—and only when the artist was thus inspired could he produce real works of art.

SIGN-WRITING AND GLASS EMBOSSING.*

THE author of this work in his preface claims for it the honour of being the first work published upon the subject. He is in error. The matter has been fully treated upon by Mr. W. Sutherland in an illustrated work published some thirteen years ago by Ackerman & Co., and chromo-lithographed by Underwood, of Birmingham, price 21s., containing plates of letters and ornaments (imperial folio) raised and shaded on ground colours, specially designed and coloured for the use of sign-writers and glass-embossers, accompanied by practical instructions—a work now exceedingly scarce. We may also notice another error into which the author has been led. Speaking of glass-embossing (page 176), he says:—"It is an incredible fact that the art is exclusively confined to the metropolitan writers. In the provinces embossed glass-work is even now seldom seen, and the art is hardly ever practised." We can only express our surprise that any person possessed of average intelligence could have made so preposterous an assertion. Why, ever since the invention of plate glass, and even before that date, thousands of feet of embossed glass have been annually executed by firms in the provinces; and, in fact, it is from these firms that the great improvements in the ornamentation of plate and sheet glass have emanated. We need only name the great firms of Chance Brothers, of Smethwick, and Pilkington & Co., of St. Helens. From these and scores of smaller firms situated in the great towns and cities of the north of England and Scotland hundreds of thousands of feet of embossed glass have been issued, not alone for the ornamenting of London spirit-vaults and gin-shops, but for the decoration of town-halls, exchanges, municipal buildings, the palatial warehouses of our merchant princes, and public and private buildings of every description. The extent to which it is used is enormous, and we venture to say that not one foot in fifty thousand of this is done in London. With regard to the book and its subject, it is evident from the text that the author is a practical sign-writer possessing a very considerable amount of literary ability. He has gathered together a large amount of pleasant matter from the history of type-founding and the various kinds of letters used in printing books. The information thus gained has been very cleverly worked up for the benefit of the student of sign-writing, but is really of more value to the printer than the sign-writer. In fact, the author has made an abortive attempt to elevate mere sign-writing to the dignity of a fine art. Sign-writing is a purely mechanical art; the forms of the letters are arbitrary. The writer is confined to certain set forms from which he cannot depart, if he does, a thousand to one but it is a retrograde movement. This being so, it is only needful for the student to acquire a knowledge of these set forms and their proper arrangement; practice will do the rest. He need not even learn to draw in order to write signs. Of course it is better that he should, but, as a rule, practical sign-writers are about the worst ornamentists possible. Our author's ideas of decorative ornament are, to say the least of them, rather peculiar. He recommends the use of the small sections of stereotype ornament the printers use for setting-up borders and corners in printing. Such a recommendation of the study of ornamental design is certainly unique, and needs no comment from us. We now turn with pleasure to the really practical portion of the work (which, by the way, occupies less than fifty pages of the 208 of which the book consists). This part of the work is really what it pretends to be—a thorough practical exposition of the various manipulative processes used in the art of sign-writing and glass-embossing. The instructions given are sound, carefully and truthfully written, and evidently such methods as the author himself practises, which is a guarantee for their correctness. Had the author confined himself solely to the practical part of his subject (which is strictly the province of such works), we should have had nought but words of praise to give him; but we really cannot see what the science of optics and the rules of perspective have to do with sign-writing.

* "Sign-Writing and Glass Embossing." By JAMES CALLINGHAM. London: Simpkin, Marshall & Co.

CONSTRUCTING ROADS.*

THIS very interesting pamphlet, though mainly intended to make known a new mode of making road surfaces, contains, as might be expected from the extensive experience of its author, much useful and important information on road-making. Mr. Mitchell states that he was a pupil of Telford, the great road-maker, and that, formerly the General Inspector of Roads and Bridges in the Northern Counties of Scotland, he has "been engaged the greater part of his life in the construction and repair of roads." We note that, in a brief historical preface, he repeats another of the many charges of plagiarism that have been brought at different times, and especially during his lifetime, against the celebrated Sir John Loudon Macadam. He points out that Macadam in many of his rules was anticipated by Mr. Edgworth, who, a man of much science for his time, was appointed by the Committee of Natural Philosophy, in Dublin, to make experiments on road construction, in carriage draught, and on the form of wheel felloes. He might have added that Tresagnet, a French engineer, was yet earlier than Edgworth in many of the principles afterwards advocated by Macadam.

All this is no doubt true, but the popular voice is just in ascribing great merit to Macadam in his reform of our common road surfaces. As Sidney Smith, the incarnation of common-sense and wit, wrote years ago,—"Many persons broke stone before Macadam, but Macadam felt the discovery more strongly, stated it more clearly, persevered in it with greater tenacity, wielded his hammer, in short, with greater force than other men, and finally succeeded in bring his plan into general use." Again, "that man is not the first discoverer of any art who first says the thing, but he who says it so long and so clearly that he compels mankind to hear him—the man who is so deeply impressed with the importance of the discovery that he will take no denial, but at the risk of fortune or fame pushes through all opposition, and is determined that what he thinks he has discovered shall not perish for want of a fair trial." Let us hope that Mr. Mitchell will be as successful.

The principle which he starts from is perfectly sound, and is, in fact, that which dominates Macadam's reform, the use of quadrangular blocks of stone or wood, the application of asphalte, and, we may add, the employment of the steam road-roller. He wishes to keep all matters soluble in water out of the road surface. This is done by using stone or wooden blocks, except at their joints, entirely so by asphalte, and in a great measure by the steam roller, which forces the fresh broken stones together before mud can get between them. It is clear that any soluble matter, or matter so constituted as, by mechanical combination with water, to form a paste, is at once acted upon by rain. This is the mud which, in an unrolled road, "forms the cementing material" of the broken stone; and which, in stone pavements, forces its way up between their joints, partly from the surface below. In this way is accounted for the, at first sight, puzzling layer of mud to be seen, during wet weather, even in the paved streets of the city of London, miles away from a macadamised road. Three or four years ago, the author carried out an important experiment, and we have never met with one throwing more light on the actual composition of our ordinary macadamised road-surfaces. He took up "2¼ cubic feet of the crust of the macadamised road in the Mall, in S. James's-park," and caused the mud which cemented the stones together to be washed clean away. This mud was found to amount to 11·27ths of the whole mass, or in the proportion of 11 cubic feet in every cubic yard of road crust. The remaining stones and grit were then examined, and parcelled out indifferent sizes, with the following results:—1 cubic yard was found to contain:—mud, 11·00 cub. ft.; sand to pebbles of 3-16in. in size, 2·40 cub. ft.; stones from 3-16in. to ¼in., 6·56 cub. ft.; stones from ¼in. to 1in., 4·48 cub. ft.; and lastly, stones from 1in. to 2¼in., 2·56 cub. ft., showing that only 1-10th part of the whole 27 cub. ft. retained the original form and size of new granite metalling.

We now come to Mr. Mitchell's own plan for the reform of macadamised or broken stone roads. He proposes to bind the broken stones together by means of Portland or of other hydraulic cement grout, in the proportions of four parts of clean broken stones, one and a quarter to one and one-third of clean sharp sand, and one of cement of the best quality, able to stand a tensile stress of 500lb. to 600lb. on a bar 1½in. square. Complete instructions are given for making a road on this plan. He prefers to make it in two layers; the first to be put down roughly for a thickness of three or four inches, and when consolidated the second layer, of the same depth, should be laid, and carefully rolled with a heavy roller. In order to obtain access to the water and gas pipes, the concrete is to be cast in blocks 3ft. by 4ft., separated from each other by 1½in. of joint, filled with concrete grout. To remove the blocks, the joint is cut out, and they are raised by a moveable crane. Mr. Mitchell states that under traffic at Inverness for the last four years and a half this kind of road-crust has given good results. The second trial, carried out on 100 yards of the Mall in S. James's Park, was a failure, "the surface breaking up under the traffic." His explanation is that the surface was accidentally rolled before the cement had consolidated, thus injuring its crystalline structure. Fifty yards laid down in 1866, at George IV. Bridge in Edinburgh, have given better results.

The idea of using concrete in this way is a very simple and obvious one; but the application is one of those that could only be fairly tested by many prolonged and careful trials under heavy traffic. We do not consider that such a road could be easily repaired—that, for instance, ruts, such as would be sure, sooner or later, to form themselves, could be rapidly and cheaply mended; cutting them out and filling with fresh concrete, would, we should expect, be an inefficient remedy, and until this concrete got consolidated the road could not well be opened to traffic.

* "A new Mode of Constructing the Surface of the Streets and Thoroughfares of London and other great Cities, by which Mud and Dust will be greatly diminished, and the Expense of Maintenance and Repair much lessened." By JOSEPH MITCHELL, C.E., &c. Second Edition. London: Stanford, Charing Cross, 1870.

ARCHITECTURAL ASSOCIATION.

AT the usual fortnightly meeting on Friday evening last, Mr. T. H. Watson, President, occupied the chair. The ordinary routine business having been got through, several new members were elected.

Mr. J. D. CRACE then read the following paper

ON THE MODES OF DECORATIVE TREATMENT ADAPTED TO VARIOUS MATERIALS.

Among the many varieties of skill which are necessary to the excellence of each work of art, there is one which, as it seems to me, lies in danger of being overlooked, or, at least, of being treated with something like oversight—I mean that particular skill, which must emanate partly from the designer, but far more from the workman, by which the special qualities of the *material* to be dealt with are recognised, valued, and expressed. At the first glance we should be apt to say that a beautiful form will be beautiful whatever the mere material in which it is shaped; but this is now so generally admitted to be a false doctrine that it is not necessary for me to pursue the arguments against it. My present object is to show that, given the design suited to stone, wood, or metal, there yet remains to the workman an excellent field for the exercise of his perception and the display of that particular skill by which every excellence of his material is made the most of. Without going the length of saying that *every* variety of *every* material calls for a special style of execution, I *do* say that the subject demands much closer attention than it receives, and that it is well to bring forward some of the more notable instances, and to point out how or where we may look for the peculiarities of texture or substance which should influence the use of our tools. Let us, then, begin by considering the *solid* materials which may be moulded or carved. The first, and most important to architects, are those materials which may be classed generally as stone. Under this head are included materials of very varied qualities and characteristics—so varied, indeed, that we almost may say that each variety requires its own treatment in sculpture. We may, however, group them together broadly under a few heads, and then, looking back historically, we shall see that the whole style of art was, in early ages, affected by the peculiarity of treatment rendered necessary or possible by the characteristics of the materials used; bearing in mind that, the most esteemed materials being used for the most noble monuments, and those monuments having the strongest hold upon the mind and the most powerful influence in art, so the working of those materials gave the keynote to the art-work of that age or country.

GRANITE.

Thus, as we find the earliest and grandest sculpture of Egypt worked in granite, the beautiful and durable stone of Assouan (Syene), so we find all Egyptian sculpture partaking to some extent of the characteristics of execution most suitable to that material. Broad, even surfaces, crudely-rounded contours and obtuse or rectangular sections prevail. A thin "arris" or an acute angle is almost unknown. The value of the material also is much enhanced by a high polish, which is only compatible with broad surfaces and bold roundings. Where greater detail is required, it is either cut deeply, at right angles to the surface, or slightly, through the polish, and left dull in contrast with the polish. And as the forms must be of the simplest and most conventional, so the detail must be very limited and very expressive.

MARBLE.

In the beautiful white marble of Greece we have a material the admirable qualities of which may almost be said to have had a large share in perfecting Greek art. The workman must have taken delight in its exquisitely even grain and pure colour, admitting, as they do, of the most delicate expression of form and of the highest mechanical finish. Indeed, it is impossible to compare the progress of Greek sculpture from the archaic to its more perfect development, without feeling conscious that the artists were gradually recognising the wonderful capabilities of their material and were led on to fresh efforts and more careful study in consequence. In addition to its beauty, the ease with which it is worked and its durability encourage the use of fine sections in mouldings, sharp arrises, and delicate detail. The even, crystalline granulation of surface is admirably calculated to express the roundings and the most subtle gradations of shade; consequently he who, overlooking these special qualities, executes his work as if in a coarser stone, throws away much of the excellence within his reach. The semi-transparency of marbles gives a peculiar value to their sections under some conditions, and occasional acute angles in section may almost be said to be necessary to the full exposition of the nature of the material. It must not be supposed that, even among the ancients, an equal amount of intuitive skill was possessed by all the workmen employed on one building. Let any one who has the opportunity examine the several blocks which formed part of the frieze and cornice of the Erectheum, now lying in the British Museum. On looking closely he will find an immense difference in the method of finish in one block and in another (compare those numbered 127 and 129). Even at this lapse of time, one can almost say that the worker of one block was thinking of his work, the worker of the other of his wages.

The student of "material" will also do well to examine very carefully the sections of the draperies and other portions of the best Greek sculptures. He will find nothing overlooked there; every surface, every edge or angle is so worked as to use to the best purpose the light which falls on it. If, too, he observes in these works the treatment of the human face and figure, he will learn how the *breadth* of light must be preserved, and how, when emphasis is

needed, the shadow must be cut so deeply as to overcome the luminous white of marble. What I have been saying applies to the white marble only. "Veined" or figured marbles admit only of the boldest moulded forms, and not at all of carved detail, which only quarrels with the "figure"—the material's natural beauty.

STONE.

In the commoner varieties of building stone, we have materials of a grit variously coarse, and more friable, both in working and in wear. These qualities necessitate coarser arrises and fillets, and, therefore, heavier contours in the mouldings. It is well to bear in mind that the apparent finish or delicacy of mouldings is to a great extent determined by the delicacy or otherwise of the narrow fillets. The colour of the common stones, again, is less even than that of marble. The treatment of the detail has, therefore, to be vigorous enough to overcome its inequality. In comparing the buildings of Greece with those of Rome this difference of treatment is very observable. The detail in stone, requires stronger definition, which is obtained by greater relief and depth of cutting; so that often where low relief would suffice in marble, high relief and bolder forms are requisite in stone. I am, of course, supposing the conditions of light or position to be equal. Climate or other special circumstances may largely affect the treatment, nor am I now considering special *design* so much as special *workmanship*. It will be readily understood that according to the coarseness or fineness or friability of the stone the treatment may be modified upon the same general rules. It may, however, be as well to enumerate a few leading points. In carved details stone allows considerable freedom. Deep undercutting is admissible and useful when not carried to such excess as to expose the subject to risk. Projecting masses must always be corbelled, so to speak, in such a way as not to have a tendency to break themselves off. Thin edges are incompatible with so friable a material, but lightness may always be given by bevelling back to the ground. Where strength is expected, a rectangular section is agreeable to stone. Indeed, a square edge seems constantly demanded, and an edge presenting an angle of less than about 60° or 75° is too weak for the material. To sum up, the ordinary building stones require a firm, vigorous, substantial treatment, with sufficient breadth and depth of cutting to overcome the more or less irregular colour, according to the distance at which the work is intended to be seen. Of

STUCCO OR PLASTER,

the treatment may be classed under two heads—that moulded by hand, and that cast in moulds. The two methods may also be blended. In working plaster relief ornament by hand, a great freedom of touch and variety of form are attainable and desirable. At the same time, thin edges or deep undercutting are rendered undesirable by the friability of the material. The degree of finish must depend rather on the conditions of application, since its texture may be rendered as fine as that of ivory, and a pure and even tone of colour may be obtained, either in the material or by subsequent tinting. Almost any degree of vigour may be given by bold modelling, keeping the lights broad and not too much softening away the tool marks. Excellent examples of plaster treatment may be seen in the ceilings of many old London houses of the period of the Georges, and the elegant and spirited stuccoes of both ancient and mediæval Italy afford valuable teaching. Where the ornament is intended to be painted or coloured care should be taken to avoid narrow quirks, which may become stopped, and thin edges, which will easily be broken. If the relief be very low an indented outline is useful. For the treatment of plaster ornament cast from moulds we cannot do better than observe Arabic or Moorish work. Ornaments produced in this way should be clear, well-defined, not undercut, and arranged so as to draw readily from the mould and require little subsequent finish. It is applicable, of course, chiefly for repeated or diaper ornament. In Moorish work beautiful soft gradations of shade are obtained, *not* by rounding or moulding the face or edge of the ornament, but by introducing two or three distinct *strata* of ornament, interlacing with each other, each on its own level—a plan in every way adapted for work cast in moulds. In combining the cast and hand-worked methods, the simpler and more rigid parts may be cast, leaving the lighter detail to show the workman's hand. Many of the foregoing remarks apply equally to

TERRA-COTTA,

in which, however, partly on account of the coarser material, and partly because its use is most often external, greater boldness of execution is demanded. A certain rough plastic touch, with rather hard edges and strong surface lines, tell best. (See the details of the Certosa at Pavia, and, for the higher forms of art, the Florentine portrait-busts of the fifteenth century, especially No. 7,621, '61, and S. Jerome, 8,383, '63, in the Kensington Museum.) Undercutting, fine arrises, and fillets should be avoided. From terra-cotta we easily pass to the *glazed* material, as Della Robbia ware, and to

POTTERY.

Here angular sections are to be avoided, the surfaces all rounded; and it must be borne in mind that as a number of small high lights only perplex, it is desirable to maintain great simplicity and breadth in the moulded surfaces, and distinctness in the outlines of the forms to be expressed. Where the design is set off by a coloured or tinted ground *without* glaze, a careful outline and sharply-executed detail are required. For examples we have but to look at the productions of Wedgwood, many of which are, in their way, perfect. Under a glaze, however fine, low relief requires a more delicate and softened treatment, with an avoidance of hard outline or sudden protuberances. Of this class of work is the Celadon ware, of which a splendid example is the "Cobden Vase" on view at Kensington. The conditions of this material are—on an opaque tinted ground, a semi-transparent white relief with a high glaze over the whole—conditions favourable to extremely-subdued relief and softened outline. I allude to these finer descriptions of pottery because, in the form of medallions, &c., they are occasionally used to decorate either the building or its accessories.

WOOD-CARVING.

The grain and texture of wood vary so considerably that comprehensive rules of general application cannot be laid down. It is not difficult, however, to show in what respects general rules may be observed, and at what points they must diverge according to the material to be dealt with. Some woods are of so fine a grain and so close a texture that they are capable of almost unlimited delicacy of finish; and of these the harder sorts will take a soft-hand-polish which places them almost on a par with ivory. I need only refer to that wonderful specimen of wood-carving, the cabinet by Fourdinois, of Paris, from the Paris Exhibition of 1867, now at Kensington. Work of this description is, however, so exceptional as not to demand so much notice as the carving of the various woods in ordinary use. In such woods as oak, walnut, or mahogany, we have materials with a more or less pronounced grain or texture, in colour not quite even, readily cut with a sharp edge, and of a tenacity altogether different from the brittle nature of stone, enabling it to bear considerable undercutting or perforation without risk. These are all qualities admitting of or requiring special treatment. To commence with the first-named condition—the visible grain or texture. It is obvious that the workman will select for his carving that wood which is most *even* in texture, grain, and colour, since all strongly-marked grain or figure tend to confuse and destroy the effect of his work. Still, even when he has done this, he has in *oak* a very apparent grain, and here and there some amount of "figure." The carver in oak, therefore, must seek carefully to execute his work in such a way as to overcome the opposition which these qualities present. His lights must be preserved broad and clear and in high relief; the leading intention of all foliage distinctly marked, the finer lines or stems preserving a sharp outline. The shadows must be bold enough to explain the forms, intensity being given by bold undercutting. Much assistance to the expression may be given by the actual tool-marks. Nothing is so fatal to the spirit of wood-carving as glass-paper. Yet, bold though the execution of the work be, it need not appear coarse; the strength and tenacity of the material allow of thin edges and considerable freedom as to detached and perforated work. But, above all things, let the wood-carver avoid a thick square edge—an edge at right angles with the face of the work This at once gives his work a *stony* character, which no mere finish will obviate. I know no examples better illustrating the exact capacities of oak than the exquisite stalls of Amiens (1528), and the beautiful panelled door enclosure by Paul van Schelden in the Town-hall of Oudenarde. There is an excellent model of the latter in the Crystal Palace. In walnut-wood we have a material extremely suitable for the carver's art. There are many varieties, differing greatly from each other; some abounding in strongly-marked, and often beautiful figure, others presenting a mellow even grain (with but a slight "streakiness"), and an agreeable grey-brown tone of colour. When this latter class of wood is used (and its fine pores are, upon the completion of the work, filled up by a judicious wax rubbing), results may be obtained as satisfactory in the way of wood as those from bronze are in the way of metal. To those who would learn the style of finish and execution adapted to walnut-wood, I would point out the numerous works of the Siennese carvers, the stalls of S. Pietro at Perugia and of Santa Maria Maggiore at Bergamo, both by Stefano de Bergamo. There are also some admirable benches and a desk in the Sala di Cambio, at Perugia, and the numerous grand doors in the Vatican likewise present excellent specimens. In the Museum at Kensington there are a few good works of this class; modern Siennese work they are, but the artist has well caught the style and method of the old carvers. I do not call to mind any prominent good example of *ancient* carving in walnut-wood in that collection. The numerous coffers in the Cartoon Gallery have no special merit of execution. I must not be understood to proscribe the use of the figured class of walnut-wood. On the contrary, this, beautiful in itself, should be used for such plain, flat surfaces as will exhibit and derive embellishment from its beauty. It will be observed in the examples I have quoted that a certain *precision of touch* is common to all of them. The lights are crisp and well-preserved, always with a view to carrying the eye along the motive of the ornament. If it be a scroll with a fine stem connecting foliage or husks, observe that the eye is always made to travel along the centre-line of the curve. The section of foliage or stem is such as to take the light in the proper direction. The fine stem is so sharply cut (though sometimes a mere thread) as never to fail of expression, either by means of its fine high light or sharp little shadow. In this way even the finest lines are not allowed to be lost in the dark colour of the wood. It will be found also that excellent use is made of the tool-marks, which greatly assist the expression of the work.

IVORY.

Holding a place superior, but closely-allied to the finer woods, is ivory. This beautiful material has been very highly prized for the purposes of art from the earliest times. Its close, homogeneous texture peculiarly fit it for the finer kinds of carving, and the beautiful surface of which it is capable, together with its soft even tone of colour, have frequently induced artists to adopt it for works of a size considerably beyond what we need consider now. The form and size of its natural growth may, in a general way, be taken to limit the size of its use, which is therefore ordinarily confined to a surface of a few inches. There is hardly any limit to the finish and elaboration of detail which may be given to a few inches of ivory. High relief or low relief appear to equal advantage, and the conditions attached to it appear most simple. The work must never be rough or coarse, and must always exhibit the exquisitely delicate texture of surface which is natural to it. Its strength admits of its being undercut to almost any extent, and of being worked to almost any degree of tenuity, whilst the remarkably soft gloss of its surface exhibits to advantage either the boldest or most delicate roundings.

METALS.

The several metals in use for ornamental purposes present conditions different altogether from those distinguishing the materials which we have been considering. If we except cast-iron, the condition of friability is wanting, and we are therefore at once admitted to the use of the thinnest sections and the most acute angles. Their different degrees of ductility also represent a special quality to be expressed. Their capability of being bent and twisted without losing their strength is a valuable quality to be recognised. In treating each separately we shall have to be guided partly by the different degrees in which they possess these qualities, partly by their colour, and partly by the greater or less extent to which they exhibit bright high lights, or are capable of receiving a burnished surface. Let us first take

WROUGHT-IRON,

for the artistic treatment of iron must be guided by its finest capability, and that is to be found in its readiness, under certain conditions, to receive the direct impress of the worker's hand. We have, then, a material of a dark colour, and which, under ordinary conditions, does not exhibit bright high lights. A vigorous treatment and strong indentation are therefore demanded for detail. Its liability to corrode prevents any reliance on the effect of fine surfaces. It possesses, when being worked, considerable ductility, of which the workman must avail himself fully; also great elastic strength, which permits it to be bent or twisted extensively without frequent support. These qualities allow of very acute sections, sharp mouldings, and narrow fillets, all of which will be found expressive, but the finer the sections the more careful must be the finish. Excellent specimens of wrought-iron ornament are numerous enough among country inn "sign" brackets, and the balustrades and gates scattered about the country, all dating prior to the present century. The Hampton Court gates (not long since removed to the Kensington Museum) are splendid examples of what may be done with the smith's hammer. At the same time, I am disposed to doubt the desirability of working the ornament to such a paper-like thinness in a material which corrodes so readily as iron.

(To be continued.)

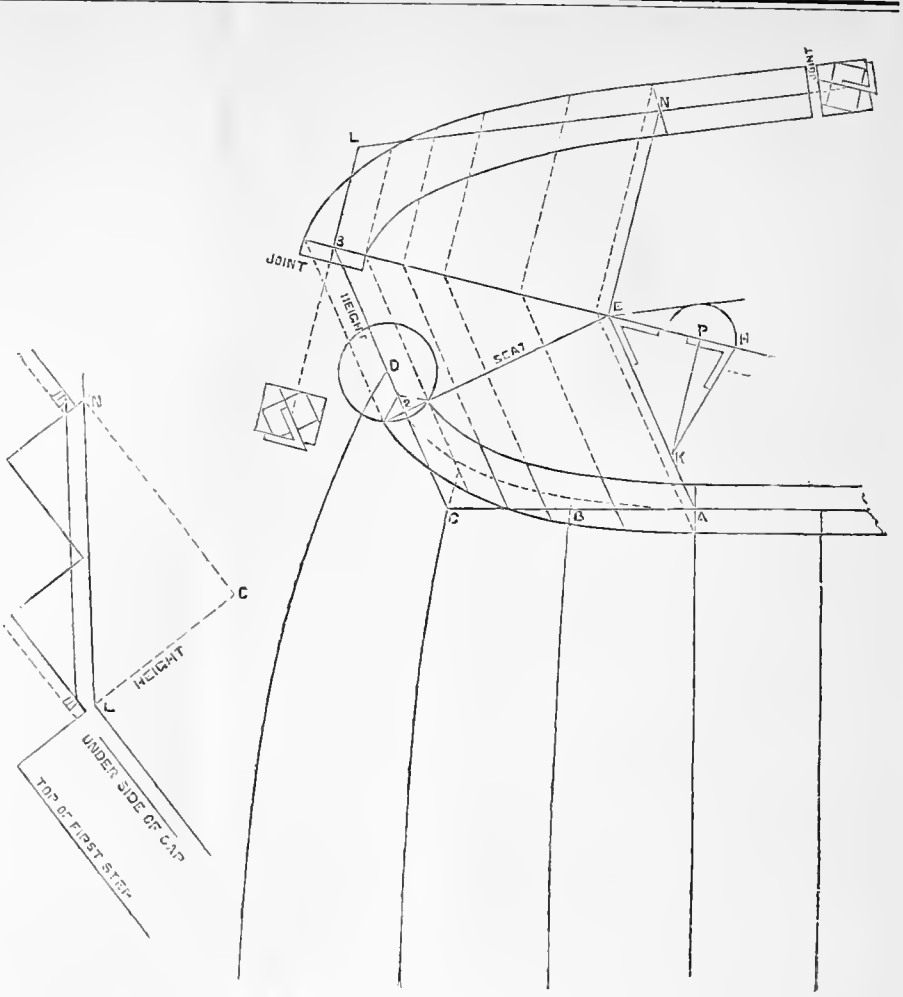
THE HOLBORN VIADUCT.

IN the course of his paper on the "Selection of Building Sites," recently read before the Royal Institute of British Architects, Professor Ansted incidentally cited the case of the Holborn Viaduct as pointing to the necessity of having good foundations. In the discussion which followed,

Mr. HAYWOOD, the engineer to the City of London Commission of Sewers, and designer of the Viaduct, concurred in the remarks of the Professor as to the selection of sites, but was at a loss to know why he dragged in an allusion to the Holborn Viaduct. If he meant to infer that the foundation had given way, he could understand the allusion, though the inference was incorrect.

PROFESSOR ANSTED here said that his impression was that the foundation had partially given ay.

Mr. HAYWOOD, in continuation, then said that as few things were so instructive as an account of a failure or a partial failure, he would narrate briefly the circumstances connected with the getting in of the foundations, from which it would be self-evident that the fault did not lie there. He hoped that at some future time, either in that room or in another place, he should be able to bring the matter more fully before the profession. The old bed of the Fleet River was 200ft. or 300ft. wide at the spot where the Viaduct is carried across the Valley, and the bed of the existing Fleet Sewer was about 22ft. or 23ft. below the old level of Farringdon-street at the point where the principal arch of the Viaduct spans that street, and this bed was of clay. The excavations for the foundations were carried 7ft. or 8ft., and in some cases more, below the old bed of the river, right into the solid blue London clay, and the foundations were got in bit by bit. Concrete of the best quality was used, and the greatest pains taken to ensure efficiency in respect of foundations. This efficiency was attained, for, on the authority of the engineers appointed by the Corporation to report on the nature and causes of the fracture of the granite columns, it had been stated as beyond doubt that the foundations would bear five or six, or even seven times more weight per square inch than they would have to bear were the Viaduct densely packed with human beings and vehicles of the heaviest description. The engineers referred to had reported that not the slightest movement had taken place in the foundations. The fracture of the columns was entirely due to bad joining. If any fault attached to him in the matter—and he spoke candidly—it was that he had trusted too implicitly to the conscientiousness of the workmen who were to carry his design into execution, and had calculated on such workmanship as he himself should have put in had he been engaged in the erection of the columns. He had endeavoured to make too fine a joint, and with such large masses of granite almost mathematical accuracy was necessary in the joining an inequality of only a sixpence in thickness being capable of causing a serious fracture.



NEW ELEMENTS OF HAND-RAILING.—PLATE XVIII.

PROFESSOR ANSTED, in reply, expressed his regret that he had made the allusion in question to the Viaduct, and begged to withdraw it in the face of the very satisfactory statement made by Mr. Haywood. From that statement it was quite clear that Mr. Haywood was blameless in the matter.

NEW ELEMENTS OF HAND-RAILING.*

(Continued from page 28.)

PLATE 18.—THE SIDE-WREATH—STARTING FROM NEWEL.

WHEN a hall is large and spacious, then the stairs starting should present a grand and imposing effect. The newel stands out, curve projects on floor, and extends on the side, to third or fourth riser, as the drawing shows.

To lay down the plan: Commence with a straight line for centre of rail; say that through A. Let A, B, C equal two square steps. Assume C, on second riser, as a fixed point. Then the line from C may be drawn to make any angle (except a right) with C A.

It will always be ordinate, no matter in what direction the line may be drawn. It causes the wreath to fall exactly level at the mitre cap, and directs the construction of mould.

Let us take C D for ordinate, and D as centre of newel and mitre cap. Here observe that the centre of newel can be made to stand at any point on line C D, and the curve on the floor be either expanded or contracted to suit situation.

This understood—draw size of cap. Set off half width of rail on each side of line C D. Draw parallel with it, cutting cap, which gives commencement of mitre. Let seat from 2 be square with C D. Next, draw from A, parallel with ordinate, cutting seat at E.

Remember that the height must be obtained before pitch can be drawn. The two square steps on the left show under-side of rail resting on centre of balusters. Set off half its thickness. This done square over N C. Make it equal to A C on plan. Then L C gives height. Let that of 2, 3 on the right equal it. Next join 3, E extended; and we have the pitch. Dotted curve shows centre of rail, and lines C 2 and C A its tangents. Set off half width of rail on each side of curve. Then draw any number of ordinates cutting pitch. Square these over. Let E N equal E A, and 3 L equal 2 C. Join L N extended. This, to be correct, must equal corresponding letters on left.

Now find points and trace curves on mould. Let the straight wood for joint equal mitre at 2. Find bevel for joint on straight shank, by drawing a line from E parallel with N L. Next, square over any point on pitch—say P. Let this be centre; and for radius a circle touching line from E, cutting at H. Join H K, and bevel is obtained. The angle formed by pitch and E A gives bevel for joint on left.

Square sections show their application.

Examine the drawing and see how the angle of tangents meeting at C affects height of newel. It is evident a riser added to a short baluster gives height of newel from top of first step to under-side of cap; because the tangents meet on second riser. Again, move point C to the right. This increases length; but, let C stand on first step; then the newel becomes shorter. Elevation on the left shows all this. Line N C being fixed and equal to tangent A C. Therefore, the length of tangents on ground plan regulates height of newel.

* This series of articles is a reproduction of ROBERT RIDDELL'S work on the subject, published in Philadelphia, and by Trubner and Co., London.

ROYAL INSTITUTE OF THE ARCHITECTS OF IRELAND.—The ordinary general meeting of this Institute was held last evening, when Mr. J. M'D. Bermingham, Associate, read a paper on "The President's Address and Building Surveyors."

INTERNATIONAL EXHIBITION OF 1871.—The following noblemen and gentlemen have consented to act as judges to select paintings for the forthcoming exhibition:—The Viscount Bury, M.P.; the Lord Elcho, M.P.; Sir Coutts Lindsay, Bart.; Mr. Alfred Elmore, R.A. (representing the Royal Academy); Mr. Alfred Clint (representing the Society of British Artists); Mr. Alfred Hunt (representing the Society of Painters in Water Colours); Mr. Henry Warren (representing the Institute of Painters in Water Colours); Mr. F. Dillon; and Mr. H. S. Marks.

Furniture & Decoration.

DECORATIVE PROCESSES.

BY "AN EXPERIENCED WORKMAN."

MUCH has been said and written both for and against the use of imitations of woods and marbles. We do not intend to discuss the question here; suffice it for us that custom, practice, and precedent sanction their use. Mr. Owen Jones, Sir Digby Wyatt, and others of the highest authority on decorative art, admit of imitations being used wherever the real wood or marble could or would be used in architectural construction. That this is a sensible and right view of the question we are persuaded that none but crochetty critics will dispute. However, we are safe, so far, in the fact of its being so universally used in all classes of houses, public buildings, shops, &c., both for interior and exterior decoration—for purposes of utility, as well as for adornment; and we may rest quite assured that its practise will never be discontinued, however much the followers of John Ruskin may preach against it. Even from an economical point of view its value is great, inasmuch as no other kind of painted work will bear cleaning so repeatedly as grained work, &c., without injury. As a means of decoration it is valuable. Beautiful combinations may be formed with the great variety of coloured woods and marbles available for the use of the artist, which in skilful hands may be worked up into the most complicated and tasteful forms; and if good taste be exercised in the selection of the colour of the woods and marbles and their harmonious arrangement really artistic works may be executed. We cannot see why works of this class may not be ranked with the other specimens of ornamental art which are usually placed on a much higher scale. However, with that we have nothing to do here, simply confining ourselves to the manipulative processes employed in working them.

How long ago, or when the art of graining first originated, we have no record, man being essentially an imitative animal, and he may have begun very early. Let that be as it may, we can only record our own experience. We remember seeing, upwards of thirty years ago, in an old mansion in Yorkshire, some imitation oak, which, by well-authenticated testimony, was proved to have been done upwards of sixty years before; and it was, at the time we saw it, undergoing the process of cleaning and varnishing, and, although dark with age and repeated varnishings, it was in a condition to last many years.

Oak graining, of which we are now about to treat, is peculiarly an English process. To an Englishman the oak tree is an embodiment of strength, grandeur, and utility; its praises have been sung and its sterling qualities lauded by poet and sage. To it the stability and beauty of our ancient baronial halls, and the half-timbered dwellings of England's sturdy squires and yeomen are due. Our churches and municipal buildings were clothed with oak, in panelled wainscot and glorious carved screens. For quaint furniture, from the throne of the monarch to the rude bench of the cottager—to all these and countless other uses has this famed English wood been applied. No wonder Englishmen are fond of this truly national tree, and hence the very natural desire to see it about them in every form—oak doors, oak sideboards and chairs, &c. Indeed, this fondness for oak has led to its being the only wood which in England is universally imitated. Wherever we go, in hall or cottage, we see this wood, either real or imitated. The beauty and novelty of its grain and markings peculiarly adapt it for being imitated, and it is a singular fact that out of the millions of feet of oak planks cut up yearly no two planks are alike. It needs but to take the thickness of a shaving off an oak board, and the figure or marks will be changed. No other wood with which we are acquainted possesses this quality; all others have a sameness and a mechanical repetition of pattern in their markings from which oak is entirely free.

There are several methods used for imitating oak, with various degrees of success. The most ancient of which we have any knowledge was done by painting the work with a graining colour, and then making all the figures or markings with the end of a tallow candle; the result was that the graining colour dried hard everywhere, except on those places touched by the tallow, which was then wiped off with a piece of flannel leaving the marks of the clean ground colour. Another plan was to mix a little dark colour with sweet oil and beeswax, and with a pencil or fitch the colour of the various markings was put in upon the bare ground colour. The graining colour was then mixed with beer, and spread over the work, and then flagged with a duster or large flat tool made for the purpose. When this was dry, the marking colour was washed off with turpentine. This system is in partial use even at this day.

The next great stride in the march of improvement in oak graining seems to have been the natural out-growth from this last process, and is very extensively used in certain districts, and notably in the metropolis. It is called "spirit-colour graining." When well and properly done it is a useful and cleanly process, having this advantage over any other method, *i.e.*, that work done with it may be grained and varnished in the same day, which, under certain circumstances and for certain work, is very valuable, especially where, as in offices, &c., unnecessary interruption of business has to be avoided. This process is carried out as follows:—To mix the graining colour, grind a quantity of the best washed whiting in turpentine; add such a proportion of either burnt sienna, Oxford ochre, burnt umber, raw umber, or part of one and part of another, according to the colour required, as will stain the whiting to the required depth of colour; then add sufficient turpentine-varnish to bind or fasten the colour when thinned to a working consistency with turpentine, which may be best ascertained by trial before commencing any important work; the colour is then spread evenly over the surface, and stippled or streaked with a duster or flat brush; it is now combed quickly (in the manner hereinafter described). If this is not done quickly, the colour sets or dries, and when once set the combing cannot afterwards be done. The colour dries quite dead. When it has stood a short time it may then be figured or marked in imitation of the marks seen in the real oak thus:—Dissolve Scotch soda in water—let it be tolerably strong—add a little burnt sienna ground in water. Now take a flat fitch (hog-hair), dip it into the solution of soda, and thus mark out or put in any figure that may be desirable, taking care not to use it too freely, or else it will run and make marks, which are not required; it must be borne in mind that wherever the soda touches there will be a mark. When the work is all figured, the whole must be well washed with a sponge and plenty of clean water, which will clear off the soda, and wherever it has touched the graining colour will be destroyed, and will wash off, leaving the figures clear and bright. The work must then be brushed over with weak beer and water, in the proportions of half beer and half water, and then over grained in the usual manner. A door may thus be grained and varnished in a couple of hours' time. The solution of soda is sometimes dispensed with, and turpentine is used instead. The veining fitch is dipped into turps, stained so as to show the marks, and is wiped off again before it has had time to dry, using a flannel rag for that purpose. Wherever the turpentine touches the spirit colour it immediately softens the turpentine varnish, which may then be wiped off, but only while it is wet; and as it of course dries very soon, the work requires to be quickly done, or else it is labour lost. This is not so cleanly in using as the soda, but good work may be done with it. The heart or sap of oak may be admirably imitated on this system, especially upon moulded surfaces. The heart must be marked in with the fitch or a sable pencil and turpentine, as before described, and while it is wet must be brushed or softened all one way, that is, in the direction in which the sap runs—the direction of its growth. If this is done well the light and dark edges of the sap of the real wood may be very closely imitated.

But the most important and best system of graining oak is the oil-colour process. It must be understood that oak has two distinct characteristics. The first is the grain of the wood, which is formed by the pores, and which always runs the length way of the plank, and, in fact, of the tree also, and this is fine or coarse as the case may be; the other is technically called "the figure"—the dapple, the veining, and the lights of the oak. These markings, almost in every case, run across the grain, and, as a rule, have a silvery reflection, and stand out lighter and brighter than the grain, and sometimes they have a light silvery edge and a dark centre. Of course, both the grain and the markings are different in different descriptions of oak. In the English oak the grain and the veining, or figure, are much finer and closer than it is in the foreign oak. The Dantzic oak, for instance, is exceedingly coarse or open in its grain or pores, and the "lights," or figure, are, as a rule, in broad and thick lumps, without much grace or beauty of form; while the figure in English oak is arranged or flows in graduated curves, having a beauty peculiarly its own. The grain and the markings require different methods of working, and there is no method yet invented does this so effectively and so well as the oil process.

Before proceeding further we must say a few words on the preparation of grounds for graining. New work should be well dusted before being primed. After the first coat is dry it should be rubbed down with sandpaper and stopped with good sound putty. Three coats should then be put on and the work sandpapered between each coat; except this be done no good work can result. The finishing-coat should be mixed with three parts oil to one of turps. The colour for light or new oak, commonly called wainscot, should be of a light creamy buff, made with Oxford ochre and white, and a little vermilion or Venetian red. Some grainers like a white ground for this very light oak, but it has a rawness of look which is not at all pleasant to look upon. For a middle shade of oak the colour should be stained with Oxford ochre, Venetian red, and a little burnt umber; and for dark oak with burnt umber, Venetian red, and a little orange-chrome. These may all be modified by admixture with black to a degree according as to whether the oak when finished is to be warm or cool in tone. And here we may note that the colour of the ground is of vital importance to the effect of the work when finished. Many persons don't care much about the ground colour so that it is light enough, as they depend upon the glazing colour to bring it up to the required shade. This we are quite certain is a mistake, for if two panels are grained, one on a white or nearly white ground and the other on a rich-coloured ground, the former cannot by any amount of glazing be brought to the same richness of colour as the latter; therefore it is the wisest plan to work upon ground colours which are of the same tone of colour, or nearly so, as the work is intended to be finished. The contrast also between the graining colour and the ground colour should never be violent. When it is so, the work has a staring vulgarity about it very undesirable. The "figure" or markings stand out

so prominently and so positive that all flatness and repose is destroyed. This is a very common fault with grainers, and one that should be avoided. This class of grainers are very fond of bright chrome-yellow grounds and of glazing their work with burnt sienna, thus making it "foxy," and, as a matter of course, ugly and vulgar.

(To be continued.)

ON ARCHITECTURAL DETAILS APPLIED TO OTHER USES.*

THE subject to which I venture to call your attention has been to me a constant source of difficulty, but it is only before a society devoted to the special study of art that I could venture on a discussion on what would generally sound like dry and tiresome details. I am concerned not with the trouble that besets artists in putting their thoughts into execution, but with certain principles of design, and I found some difficulty in finding a suitable title or description of the remarks I may have to make. By the title I have chosen I mean the principle upon which designers make use of the various constructive members of buildings which are the necessities of construction, and which in architectural structures offer so many opportunities to artists, rather than think out methods suitable for object they have to design. It is the principle of borrowing and applying rather than inventing in each case. I take it for granted that objects differing in size and in use, in material, colour, durability, and so on, differ also in dignity and in capacity for decoration. Architecture and furniture, for instance, religious monuments, tombs, and sepulchres, as contrasted with looking-glasses and vases, cabinets and chests, chairs and tables. So, again, very large objects and very small ones—paintings on the walls of cloisters and the halls of family houses, and the little fanciful decorations of fans and snuff boxes. For all these various uses of inventive design there seems to me in the very nature of things to be a certain suitableness, which we will call *propriety*. How large in treatment, how full in colour, how bold in relief, how simple or how detailed, how light and open, how slight and unlaboured, or the reverse—these are conditions or modes of treatment and design which have each their own opportunities. Each and all these methods or ways are suitable in certain cases. The most delightful impression we receive from the sight of good designs and from the study of various forms of art of good periods is the impression not only that a design is skilful and graceful, but of its absolute propriety. Much that is rude, poor, apparently careless, that we meet in art is admirable in its own time and place. It possesses this quality of propriety. The Greeks amongst the ancients, the Japanese amongst existing people, seem to me to have the gift of working in this way. Imitators or students all seem more or less to fall from their pre-eminence in this respect. Yet students of these schools have, I daresay, in many notable instances possessed superior knowledge, or some, perhaps greater skill. It would be hard to say that the artists of any period surpassed the science of Michael Angelo or the grace of Raffaelle, or that the porcelain painters of Dresden, or the French and Italian designers of the time of Martin and Watteau were not, in many ways, superior to the Japanese artists. Yet the Greeks treated sculpture and painting and the Japanese treat small decoration of all kinds with greater mastery, and with a more perfect perception of propriety. In one case it seems like a traditional gift to the race, and in the other a grand but a laborious accomplishment.

In order to get to the more immediate consideration of my present subject, I must make some attempt to analyse the sources of the satisfaction we derive from architecture—I mean good architecture, as distinct from the decorations for which architecture gives the opportunities. It must be remembered that the monuments of architecture which have delighted and astonished the world are storehouses of arts more delicate, beautiful, and impressive still—I mean painting and sculpture. The architecture of Greece, of Egypt, and of Assyria, as well as of the cathedrals, churches, and palaces of Italy and Northern Europe, have offered space and opportunity for the sculptures of Phidias and Praxiteles, and held once, no doubt, the paintings of Zeuxis and his scholars—though these have perished—and for the master efforts of a thousand artists. Of vast multitudes of these we know nothing—*Careut quia vate sacro*. No poet has handed their names down to posterity. What we *do* know, however, of the greatest of these we owe to the preservation of the architectural monuments that enshrine them. Cimabue and Giotto, Memmi, Gaddi, Angelico, Pinturicchio della Quescia, Da Vinci, Raffaelle, Michael Angelo, Peruzzi, and endless other names would be imperfectly known to us had we lost the buildings which contain their greatest works. The architecture which enshrines these delightful treasures would often be poor and without value if they had been destroyed. Nevertheless, architecture may be considered in its structural character, without reference to these beautiful additions, and it has, or ought to have, a certain dignity and impressiveness without them.

The component elements of architectural construction are very few and simple. The causes of the pleasure we derive from it are also sometimes most strange and contradictory. If we rob the Parthenon of its sculptured decorations, or, looking at it as a traveller would now see it, if we can deprive that intelligent and imaginative traveller —for Mr. Cook probably takes no others now to Athens—if we deprive the traveller of his memory on the subject of these decorations, and take away "Murray's Handbook," it would be difficult for him to say why he would be so much pleased by the Parthenon. The memory helps to fill up the gap in the imagination and the gaps in the sculpture —for much still remains there. But if nothing remained at all—how then? Well, he would see in the Parthenon certain exquisite accomplishments in the way of proportion, structure, and masonry. How exactly and wonderfully these structural principles are carried out, and how scientifically the lines of the floor and steps are laid, the columns proportioned, we may learn from the learned treatise of the accomplished architect Mr. Penrose. The columns of the front are set and inclined with a delicate succession from the outside; there is a bulge in their outlines scarcely perceptible in the floor-line, a convexity extremely slight. In the determination of the proportion of width to height there is a certain obedience to mathematical laws, and so on throughout. Every line of that typical building is, as we should say, "felt" throughout. If the student compares the sections of the flattened rolls that form the capitals of the Parthenon with those of similar capitals from Pæstum and elsewhere, a certain sense, a *feeling* for beauty, is everywhere discernible. The flatness of these sections in the centre; the continued variety of their curves; the place, the number, and the proximity to each other of the indented rings below, and the size and arrangement of the flutings; the absence of base—all these are details infinitely small, but they are of infinite importance to the effect on our eyes and imagination. It would take the traveller longer to understand these beauties than those of the frieze and metopes and the pediment if he could see, or, not seeing, if he is able to suggest them to his memory. Nevertheless, from all these minute excellencies we obtain elements of real pleasure and satisfaction. It is not to be supposed that ordinary sight-seers enter into these minutiæ. It is pretty certain that few of them do. But it is by no means to be denied that they would experience real pleasure from moving about the Parthenon, looking at it and becoming familiar with what is in itself charming and delightful, though wholly unanalysed and very imperfectly observed. Do we not feel, in a thousand instances, the charm of certain objects and certain people, though for the life of us we cannot properly account for it? The conversation of the learned or intelligent, and the mere presence and demeanour of some persons, spreads, as we are in the habit of saying, a charm around them. Well—good architecture spreads such a charm. If it is beautifully decorated, it does a great deal more, as the graciousness or brilliancy of charming people when they speak to us. But good architecture has beauties and charms of its own, apart from these additions, which are, in the more proper and true sense, beautiful works of art. We have spoken of the architecture of a building which we shall all easily select as a type of excellence. There are other productions of architecture, other results of mere structure, which have not these exactnesses, and yet impart immense pleasure. Nuremberg is a beautiful town. Rouen used to be another. In our own country, Oxford is considered a beautiful town; the High-street is pointed out as a beautiful street. How is this? Of the exactness of mathematical proportion, and of the subtlety of lines, curves, and so forth (which, in a building like the Panthenon, open up a sort of mine to a learned commentator), there is nothing whatever to be seen in such a crooked irregular street. With the exception of one single spire that goes to complete a long and varied line of buildings, and one tower that ends it, there is not a structure that claims in any sort of way the merits of perfection in architecture. The irregularity, the oddness, the disproportions in detail, the crookedness of the street and its component buildings, are reckoned as beauties. In fact, elements that taken separately constitute so many faults or solecisms, taken together make up an attractive whole. On the other hand, the Classical revivals of the French Empire, and some of the modern Classical palaces and buildings of Germany, are considered, with all their observances of rule, as tame and uninteresting. To take another instance. Every one knows the peculiar scale of proportion on which Michael Angelo constructed the details of the famous Church of S. Peter at Rome. The columns and their bases and caps, the arches, architraves, mouldings, strings, and so forth, are all on such a scale that the same proportions are observed as if a building of what, for convenience, we may call usual or moderate dimensions in that Roman style had been enlarged. The figures of children that support the basins at the entrance, instead of having the proportions of Nature, are 9ft. high; doves that are sculptured amongst the decorations are as big as turkeys: all this as well when near the eye as elevated 200ft. or so. This particular feature of the proportions of S. Peter's has been criticised two ways. Michael Angelo's own feeling on the subject, it is right to say, has been transmitted to, or adopted by, most of his critics. The enormous extent of his entire structure is not appreciated at first sight, owing to the preservation of proportions to which the eye is accustomed, and the gradual perception by those that enter it of the size of the building has been looked upon as one of its leading perfections. On the other hand, intelligent critics maintain that great height and size in buildings are not features to be disguised, and that the changes of usual proportions in the constructive details that are so required should be observed: that as in Amiens Cathedral, or Cologne Cathedral, or Westminster Abbey, *height* is the great element of grandeur, maintained and impressed upon the beholder, so the height and the size of S. Peter's should be made to strike the eye of every one that enters, and to do it intentionally and at once. I do not venture to pronounce on such a divergence of opinion. But it will be allowed that the effect produced on the minds of men by details, proportions, or other elements purely structural, is very great. S. Peter's, as every one knows, is a storehouse of beautiful works in inlaid marble and stones, in mosaic painting and sculpture, in bronze and marble. All these beautiful details, however, are independent of what I am now considering, the powerful effects of pleasure or of disappointment by structural elements alone.

(To be continued.)

* By J. HUNGERFORD POLLEN, Esq., M.A., of the South Kensington Museum. Read before the Associated Arts' Institute, Saturday, January 7, 1871.

HOLBORN VALLEY IMPROVEMENT.—The whole of the west wing of the Farringdon Market buildings is in course of demolition to make way for the new street from Ludgate-hill Circus to Holborn Circus. The street will be named S. Andrew's-street, after the patron saint of the parish.

NEW OFFICES FOR THE CITY OF LONDON UNION.—We have already announced in the BUILDING NEWS the result of the limited competition for a design for these buildingt. At the last meeting of the Board of Guardians, a report from the Building Committee was adopted. The report recommended that Mr. Hudson should be informed that his plans were approved as the best plans, and that he be employed to superintend the building in Bartholomew-close. That Mr. Chambers should be informed that he was entitled to the second premium for the second best plan, viz., £50, and that Mr. T. Chatfield Clarke be informed that he was entitled the third premium for the third best plan, viz., £30. It was also resolved to submit Mr. Hudson's plans to the Poor Law Board for approval, and to take the necessary steps for clearing the ground of the present buildings.

The Surveyor.

ON THE PROPOSAL FOR MAKING OWNERS LIABLE TO THE PAYMENT OF A PROPORTION OF LOCAL TAXATION.

THE following paper was read at the ordinary general meeting of the Institution of Surveyors, on Monday last, by Edmund Rushworth, Member, Mr. Richard Hall, President, in the chair.

It appears by Parliamentary reports that the local rates and taxes, in the metropolis alone, amounted in the year 1867 to upwards of £3,000,000, and in England and Wales to £16,783,220. If any material alteration be made in the mode of levying this large amount, it is evident that existing arrangements between landlord and tenant would be seriously affected, and I am sure, therefore, I need not apologise for bringing the subject under your notice.

It has occurred to me that the most convenient method of doing this will be to call your attention, as briefly as I can, to some of the evidence given, and the arguments used with reference to the proposal for making the owner of house and land property pay a proportion of the local taxation now levied almost exclusively on the occupier.

This will, it seems to me, be a better way of raising a discussion on the general principles involved, than the reading of an essay to enunciate any personal opinion I may happen to hold on a special branch of the subject.

The success of the property tax (which is paid entirely by the owner, notwithstanding any previous arrangement that the occupier should pay all taxes and rates, whether parliamentary or parochial), probably encouraged Mr. Goschen to move for a Select Committee of the House of Commons, to inquire whether the burden of local taxation on land and buildings might not equitably be divided between the owner and the occupier.

The Select Committee of the House of Commons on Local Taxation, appointed in pursuance of Mr. Goschen's motion, reported on the 15th July, 1870 (*inter alia*):—

(*c*) "That in any reform in the existing system of local taxation, it is expedient to adjust the system of rating in such a manner that both owners and occupiers may be brought to feel an immediate interest in the increase or decrease of local expenditure, and in the administration of local affairs."

(*d*) "That it is expedient to make owners as well as occupiers directly liable for a certain proportion of the rates."

(*e*) "That subject to equitable arrangements as regards existing contracts, the rates should be collected, as at present, from the occupier (except in the case of small tenements, for which the landlord can now by law be rated), power being given to the occupier to deduct from his rent the proportion of the rates to which the owner may be made liable, provision being made to render persons having superior or intermediate interests liable to proportionate deductions from the rents received by them, as in the case of the income tax, with a like prohibition against agreements in contravention of the law."

(7) "That whilst it is necessary to make provision for limiting, as far as practicable, the disturbance of existing contracts, it would be on many grounds undesirable, and almost impracticable, to extend the exemption of property held under leases from the operation of the proposed changes until the expiration of such leases."

(9) "That the difficulties of the case would be equitably met by exempting the owners of property held under lease from the proposed division of rates for a period of three years, and by providing that after the expiration of that time, the occupiers of that property should be entitled, equally with all other occupiers, to deduct from the rent the proportionate part of the rates to which the owner may become liable, power being given to the owner at the same time to add to his rent a sum equivalent to the like proportionate part of the rates calculated on the average annual amount of the rates paid by the occupier during the three years above referred to."

The following are a few notes of the evidence taken before the Select Committee:—

Mr. Henry Arthur Hunt considered that "ground landlords had already paid their share of such local taxes as were then in existence in the diminished ground rent which they obtained, in consequence of the existence of such taxes having been used by the builder as his reason for not giving more ground rent, as the liability for payment of such rates would decrease the rent he could obtain for the building when erected.

The freeholder, in effect, said the value of the house is due to the site, and if there were no rates and taxes he would require more ground rent.

If the local taxation were taken off altogether the owner of the land would put it upon the price of the land, and the occupier would not be benefited."

Sir Sydney H. Waterlow (Chairman of "The Improved Industrial Dwellings Company") said, "there is no doubt that when a building lease is taken, the landlord does get less ground rent if the rates are very high."

Mr. Clare Sewell Read, M.P. (a Norfolk tenant farmer), said: "I believe that if the owner of land had to pay half the local rates he would be sure to recoup himself whenever there was a re-arrangement of the rent. In all probability he would make it safe in this way. I believe the average rates are about 3s. 4d. in the pound in England and Wales, and if the owner were to pay half, viz., 1s. 8d., he would say to the occupier, in order to make himself safe, 'I shall charge you 2s.,' and he would get it on land—I do not say on houses.

The competition for land is such that the owner would be able, if there were an increase of rates, to throw it entirely upon the occupier.

The owner takes very little interest about the rates; he is not so much interested in them as the occupier.

I prefer charging half the rates upon the income tax to charging half the rates upon the 'owners' of land, as every one ought to contribute according to his ability, mortgagees included."

Mr. Elias Pitts Squarey (surveyor and a tenant farmer) said, "the poor rates on land are paid obviously by the tenant, but they are borne ultimately by the landlord.

I think the tenants would be pleased at a division of the rates, as in the event of increased expenditure by the county board the landlord would share the payment."

Mr. James Caird (a Tithe Commissioner) said: "In Scotland the poor rate is divided equally between the owner and occupier, and is collected one-half from each, and I think that the same system could be advantageously introduced into England, and would give the owner a greater interest in the rating."

He admitted that on a re-adjustment of rent of land in Scotland, the whole of the rates do practically go in diminution of rent.

Sir John Thwaites (Chairman of the Metropolitan Board of Works) considered that if the metropolis generally is benefited by better sewerage, purification of the Thames, embellishments such as the Thames embankment and improvements generally, it is a hard case to charge the occupier wholly with the expense because he happened to have agreed many years ago to pay every rate and tax, and therefore he thought that as the owner benefits in reversion by obtaining an increased rent, he should now bear part of the increased local taxation.

He would cast part of the local rates upon the ground landlord because he benefits in reversion, but admitted it would be unfair to tax "a tenant for life" of ground rents, who has no reversion.

He added that the occupier for the time being should pay half the local rates; and that the owner's half should be apportioned among the respective persons who make up the "owner," like the property tax, which reaches ground landlords and mortgagees.

Mr. Thomas Avery (late Mayor of Birmingham) said: "At the time of letting property on lease, the actual amount of rates is an element in the contract; they, therefore, come out of the owner's pocket, and the additions to those rates come out of the occupier's pocket till a re-adjustment takes place."

Mr. R. Dudley Baxter said: "The received doctrine in political economy was that the rates fell on the occupier. Adam Smith says that the building rent is the interest or profit of the capital expended in building the house, and is regulated by the ordinary interest of money.

The rates must necessarily fall upon the occupier, because, if they reduced the rate of profit below the average rate of profit in the trade, there would be a cessation of the supply of houses, and the demand would increase till the rents rose up to the point in which it was thrown upon the occupier."—*Vide* Adam Smith, McCulloch, and J. S. Mill.

He admitted, if farms were put to competition, the occupiers would bid with reference to the amount of rates to be paid by them, and, therefore, the rates would come out of the pocket of the owner.

He thought, if mortgagees should be charged a portion of the local rates, according to the amount of the interest received (as in the property tax), it would lead to their demanding a higher rate of interest.

Putting local rates upon the owner would, in the long run, lead to an increase of rates and an increase of the taxation upon land and real property.

He added that, as the rents of land are generally below the annual value, an attempt to cast half the local rates upon the owner would lead to his having his farms re-valued, which would tend to the disadvantage of the occupier instead of to his relief, as the increased rent would more than counterbalance the relief in rates.

The above quotations will serve to indicate the general character of the evidence given before the Select Committee.

It appears to me that the views of those who argue in favour of the proposal are:—

First. That it will give the owner a direct interest in local taxation, and induce him to attend the local boards.

Secondly. That, as respects improvement rates, occupiers should not bear the whole burden, since in yearly tenancies, or short leases, the owner benefits in a much greater degree than the occupier, who only enjoys the improvement for a limited time.

The opponents of the proposal maintain, on the contrary,

First. That the right of free contract between owner and occupier will be interfered with; and that there are very few owners or occupiers in the metropolis desirous of being fettered in the manner proposed.

Secondly. That if you force owners of London property to a frequent re-adjustment of rent, it must lead to their granting short leases, thereby discouraging outlay by occupiers; and in respect of premises used for trade, keeping the occupiers in constant uncertainty, to the manifest injury of their business.

Thirdly. That owners of property in London are generally capitalists, not living on the spot, and quite willing to leave occupiers (who have the local knowledge) to attend the boards, as at present.

Fourthly. That assuming that on re-letting, the owner succeeds in adding to the rent an annual sum equal to the burden cast upon him, the so-called "gross annual value" will be increased by that amount, and the imperial taxes, such as income-tax and house-tax, will be charged upon that increased "gross annual value," unless care is taken to provide for altering the present method of assessing it.

Fifthly. That if the owners are not able to cast the burden back upon the occupiers in the shape of increased rent, it follows that the owners will be mulcted in an increased property tax of about 2s. in the pound, whilst the fund-holder and other persons, not owners of land or houses, will go free.

Sixthly. That an increase of permanent burdens will diminish the number of years purchase for which the property will sell, for example:—

	£
A house is held for upwards of eighty years, at a ground rent of per annum	2
If the legislature charges the owner with half the local rates, say half of 4s. in the pound, and the gross annual value is assessed at £300, it follows that the property is burdened with an extra annual payment of 2s. in the pound, viz., .	30
Total	£32

It has thus lost one great attraction to the capitalist, who will probably offer one, or perhaps two, year's purchase less than he would have done had the burden remained at the almost nominal sum of £2, notwithstanding that he has the chance of adding that increased burden to the rent.

The questions, therefore, I would venture to submit to the meeting are:—

Firstly. What would be the general advantage gained by the proposed transfer of a proper-

tion of the liability to local taxation from the occupier to the owner?

Secondly. What would be the effect of this transfer on the rental and saleable value of house and landed property?

Thirdly. Would not the advantages, if any, be more than counter-balanced by the great disturbance of existing arrangements between owner and occupier which in consequence must take place?

An animated discussion followed, and a vote of thanks was accorded to Mr. Rushworth for his paper.

ON THE RELATIONS OF GEOLOGY TO ARCHITECTURE. — CONSIDERATIONS ON THE SELECTION OF BUILDING SITES.*

By PROFESSOR D. T. ANSTED.

(*Concluded from page* 35.)

IT is exceedingly important that the exact physical conditions of the formation of the alluvial beds of rivers should be clearly understood by practical men. It is by no means the case that the present bed of a river is the only part where loose and uncertain material exists, nor is it at all necessary to assume any change of level, still less any great convulsion of nature, to account for the phenomena. They may be studied in every valley where the stream is left to take its natural course; but in England, and in many other countries where land is valuable and cultivation carried on extensively, the rivers are never left to themselves, and therefore the changes that explain and illustrate these conditions are not perceived. In a natural state a river rarely follows the same course through its valley many seasons in succession. Either it chokes up its old bed and steps aside to form a new one, or, owing to a torrent, it cuts itself a new course altogether, and leaves the old bed dry. All our river beds have been formed in this way. It is not that the quantity of water brought down varies very much, but that the circumstances change, and new channels are cut, the deposits of course shifting. The whole width of the valley through which a river runs is of the same nature, and the deposits are due to the same cause. Hence the variety in the foundations in different parts of a valley far removed from the present course of the stream, which has not perhaps been allowed to shift for many centuries.

But in addition to ordinary alluvial bottoms resting on clay, limestone, or sandstone, as the case may be, and consisting of the usual admixture of sands, clays, and river gravels, are the instances in which the river valley has been ploughed out by the action of ice, and has received large deposits of boulders, boulder clay, and the usual accompaniments of fine and coarse sand and gravel. Gravels are frequently found at levels very much above the bottom of the valley, and they not unfrequently even cap the hills through which the river is cut. The same kinds of gravel often occupy the valleys themselves.

Excellent as gravel is as a foundation when in sufficient quantity and uniform in texture, it can hardly be trusted unless its history be known. The gravels called diluvial are often comparatively free from loose sands and clays, and are then excellent for every purpose required by the architect or engineer. They are sound, well drained, healthy, and generally yield water at a small depth. But it is not so with the gravels occasionally found with boulder clay, nor with ordinary river gravels, and thus, as I have already pointed out, the history of gravel is an important inquiry when it is proposed to construct buildings upon it.

Natural drainage is very important in all large buildings. Without this, even if the foundations are sound, moisture will rise up by capillary action through almost every variety of stone and brick, and will in time deface the building and increase the action of weather on the surface. Certain rocks drain naturally, and are safe. Others may be drained with little difficulty, and may be made safe. Others, again, will tax the ingenuity and experience of the most accomplished architect, and will, after all, be only partially cured. There cannot be a doubt that in this latter, and also in the second case, the constructor would be greatly assisted by knowing the nature of the enemy he has to deal with, and this can only be done by a knowledge of rocks generally and of the local geology.

In speaking of the applications of geology I have avoided the mention of particular rocks as much as possible, because it is not so much the rock as its condition that affects the practical man. I have known granites porous and absorbent limestones compact, and non-absorbent sandstones offering every possible variety in every respect, and even clays very different in different places. What is wanted is such a general acquaintance with the principles of stratification and the nature of rocks as shall enable the practical man to make the best use of the conditions he has to deal with. I cannot lay down rules that can be made use of without further trouble; I can only point out the key which will unlock the difficulty in each individual case, if it is applied properly and intelligently.

Water supply from springs either at or moderately near the surface is a very essential matter in the case of buildings intended as habitations removed to some distance from pure running water. But it is now well known that however pleasant clear spring water may be to the taste, it is capable of containing and does in certain cases contain injurious ingredients sufficient to render it a fatal poison. There can be no doubt that certain superficial deposits and certain rocks are liable to induce this state in the water, while others are not. It is evident that the causes of events of this kind should be known to the architect, and it is highly desirable that he should be acquainted with the theory of springs, at least of such as are likely to affect buildings. Absorbent gravels resting on non-absorbent rocks may be expected to introduce poison into water when the ground is liable to be covered with decomposing animal or vegetable matter, or with sewage, for the rain entering them cannot fail to carry in water loaded with as much of such impurities as it can contain. Such of them as are soluble in water will certainly therefore mix with it and render unwholesome all the water pumped from the bottom of such a deposit.

On the other hand, where water has a free exit from rocks, it is almost impossible that such injury can take place to any great extent. Land springs and artesian springs from basins are dangerous. Springs from hill sides or artesian springs reaching water tapped in its progress to an outlet are generally safe. How is it to be known what is the nature of the springs without some reference to the science of geology, and some knowledge of the laws of superposition of rocks?

The whole subject of the weathering of rocks deserves the careful study of all who have to deal with stone and brick. All material without exception is affected by exposure, but while some will remain almost unchanged, and even harden when left to the action of the air, other kinds will at once decompose and rot. It is not always the hardest that is the best. This is especially the case with flags or stones splitting with parallel faces. Many very good flagstones are formed by the exposure of quarried and squared blocks during one winter, and then in the following spring splitting the mass by wedges in the cracks indicated. If left longer they can no longer be split with advantage, and after a time it becomes impossible to split them at all. Something of this kind happens with all stones. After being quarried, stones are for some time in the state called green, and after exposure to a certain extent they are said to be seasoned. In the latter state they are regarded as fit for use, but after all it is doubtful without experience whether they will be permanently sound. It is evident that if we knew more of the history of stones we should be able to use them to better advantage.

The study of stones in the quarry, and a careful examination of the effects of weathering and disintegration by the action of rain and frost of the same stone in the immediate neighbourhood, whether naturally exposed or placed in buildings of any kind, combined with a knowledge of the chemical composition, the peculiarities of aggregation, and the natural history of the stone itself, and the beds with which it is associated, will very often suggest to the intelligent observer its probable weak points for the special service for which it is designed. There are accumulated stores of information of this kind that should be familiar to all who have to decide on the selection of a stone, and it should be remembered that stone is, in the nature of things, an altered form of a very miscellaneous deposit, and that without especial care in selection and placing it is next to impossible to secure a large quantity of perfectly even quality.

You will observe that I have included a great variety of subjects as embraced within the very important subject of building sites, but I trust you will not think that I have done so without sufficient reason. I am well aware that in modern constructions beds of concrete play an important part in forming artificial foundations, and are much trusted to in keeping out damp and preventing unhealthy miasma. I wish to point out that however useful such an avoidance of the difficulty may be, it should not be trusted to implicitly, and I think it would be easy to show that there are cases where the danger and mischief would only be postponed for a time by such contrivance, and would reappear and act with full force when by irregular pressure on a bad and shifting sub-soil the concrete becomes cracked and crushed long before the time has come when the building would begin to fail by reason of age and general wear.

I assume as entirely beyond discussion that in the exercise of his profession the architect desires only to do justice on the one hand to his own inventive genius, skill and reputation, on the other to the highest interests of his client. I have endeavoured to show that in order to do this he must inform himself concerning and be to some extent familiar with the principles and applications of the science of geology as now understood. He must from time to time call in the aid of this science to decide matters of vital importance, and he cannot do so properly without making them a subject of serious and special study. I have not entered into details, as they could hardly be fitly discussed in this place, but I have endeavoured to illustrate and explain the principles to which I think your attention as architects should be directed.

Since this memoir was in type, my attention has been directed by my friend Dr. Letheby to a pamphlet by Dr. Pettenkofer, in which attention is drawn to the great influence of subsoil and rock on certain diseases, especially cholera and typhus. Dr. Pettenkofer points out that in the case of Gibraltar and Malta, it was proved, by British statistical returns, that at a time when cholera was raging over a large area there were certain small localities that escaped. On investigation, it was found that whereas the subsoil to a great depth,—and in the case of Malta the rock—was eminently porous and permeable, the spots that escaped were situated on impermeable clays. There can now be no doubt that the health of a town site is greatly influenced by the condition of the rock and soil on which it is built, and that generally a moderately porous soil, admitting of the removal of moisture by drainage, is conducive to health, especially in a damp and comparatively cold climate like that of England, and also that with us, gravel and limestone, as subsoil and rock, are healthy as well as pleasant. But it is equally certain that where the underlying rock is deep and permeable, admitting of a considerable alteration of the level of the surface of permanent wetness—which is usually found to exist at some depth, however, under such circumstances, but which varies with the season—the result may be different, and it may require both knowledge and judgment to decide as to the relative values of sites, even with regard to water only. It is also true that wherever there is a great collection of human beings, living over a permeable soil and rock, the effect of the accumulation of refuse and sewage cannot but be felt in course of time. The water percolating from the surface will carry down organic matter, and thus in time it will inevitably make itself felt, by generating unhealthy and miasmatic vapours, occasionally reaching the surface. But there is another question to be considered, which in warm and dry climates rises into great importance, and with regard to which the observations of Dr. Pettenkofer are very suggestive. All rocks are capable of absorbing, and therefore also of containing, a certain quantity of atmospheric air, either in its normal state, or replaced by other gases. No doubt a certain change in the constitution of the gases absorbed may take place, in consequence of the connection well known to take place in porous and spongy solids when mixed gases pass through them. The quantity of air or gases contained in all rocks must vary, and must be affected by changes of weather. During dry and hot weather, large quantities are given off, and during colder weather re-absorbed. In rocks, then, that contain much air, either in consequence of their great absorbing power or other laws, when there has been received into the body of the rock, by percolation from above, any quantity of organic

* Read before the Royal Institute of British Architects.

matter, and this organic matter has become putrid, the gases given off during hot summer days are liable to become dangerous miasma, and when cholera and fever are prevalent are especially liable to incur infection. I cannot but attribute to this cause the extremely bad sanitary state of some districts in the Mediterranean, healthy enough so long as there is rain, but poisonous in the dry autumn, and in these cases I can easily understand that the intervention of even a small thin band of clay may be a source of safety, and the more so the nearer it is to the surface.

I need offer no apology in pointing out these facts and inferences in a memoir on the subject of building sites, and of which the application of geology to architecture is the professed subject. Sanitary considerations connected with and arising out of topographical and geological positions can never be dissociated from the practice of architecture, and I am sure you will agree with me that all knowledge that can help to a conclusion in such matters is not only desirable, but ought to be considered indispensable to the architect.

PEMBROKE COLLEGE, CAMBRIDGE.—BUILDERS AND ARCHITECTS.

THE attention of all builders who may be about to tender for these works is directed to the following conditions which are to form a part of the contract:—

The decision of the architect to be final and binding on all matters relating to the meaning and intent of the drawing and specification, as to mode of construction and quality of materials, as to reinstatement of defective work, as to the date of completion, and as to the time and amounts of all payments to the contractor.

Should any difference arise in any other matter than as above, a reference to be made to an architect to be nominated by the President of the Royal Institute of British Architects for the time being.

The Builders' Society have lately protested against similar conditions proposed for the New Law Courts, and the Chief Commissioner of Works has altered them, and it is hoped that all builders will refuse to tender under such conditions in future. It is plain that in the above conditions the power of the architect is absolute in everything, and that the reference suggested is an illusion, as there would be no question open for arbitration. Similar conditions have been stigmatized by the judges in a recent case, Jones v. St. John's College, as one-sided, unjust, and improper for any builder to subscribe.

XYLONITE.

SOME time back we (*English Mechanic*) gave a short account of a substance first exhibited at the Exhibition of 1862 under the name of Parkesine; but as this material has been much improved, and is now largely manufactured for commercial purposes, it will probably interest our readers if we give some further information concerning its preparation and the various uses to which it is found applicable.

The material, then, which was formerly known as Parkesine, from its inventor, a Mr. Parkes, of Birmingham, and which has been renamed xylonite, from the Greek *xulon*, wood, is manufactured from wood or woody fibres, which are converted by the action of a mixture of sulphuric and nitric acids into a substance called xyloidine. This xyloidine, by means of patented machinery and solvents, is reduced to a sort of collodion, which forms a base for further operations, and the manufacture of articles almost too numerous to mention. The waste stuff from cotton and flax mills is the material generally employed in the preparation of xylonite, but wood, woody fibre, fibre-producing grasses, old rags, old rope, starch, and "half-stuff" of the paper-makers are of nearly equal utility. These substances must be first freed from all foreign and useless matter by boiling with alkali or soap and water; they are then well washed and dried, leaving nothing but the almost pure fibre for after treatment. A certain quantity of this fibre is then immersed in a mixture of four parts by weight of sulphuric acid, one of nitric acid (both concentrated), and one of water, previously prepared and allowed to cool to 70° or 80° Fahr., where it remains for periods varying from one to twenty minutes according to the degree of solubility desired. After removal from the bath, the liquid is drained or pressed out as expeditiously as possible, and the fibre washed in repeated changes of water until that liquid no longer affects a test-paper, when if the fibre, which is now called xyloidine, retains any colouring matter, it may be submitted to the action of the ordinary bleaching agents without injury to its chemical condition. It is then dried at a low temperature, or preferably by pressure, and is ready for the process of dissolving. So far the operations are similar to those adopted in the preparation of collodion for photographic purposes, but the solvents employed in the manufacture of that substance are too expensive for use in the production of xylonite, and recourse has been had to solvents, either fixed or volatile, or mixtures of both, by means of which the condition of the xylonite may be varied from the flexibility of morocco leather to the hardness of ivory or stone. The volatile solvents generally employed are wood-spirit, mineral naphtha, alcohol, aldehyde, benzole, and some other of the hydrocarbons; whilst the fixed solvents consist of linseed, castor, and other vegetable oils, with the addition of camphor. The employment of these fixed or non-volatile oils is one of the more recent improvements, avoiding the inconvenience previously caused by the contraction of the material, and the loss by evaporation of the volatile solvents. The castor-oil solvent, which is used in the production of flexible xylonite, is prepared by heating two parts of the oil to between 250° and 300° Fahr., and dissolving therein one part of camphor. While in the heated state, the xyloidine is added, and in the proportion of one part to five of the solvent, stirring is sufficient to reduce the materials to a thick paste; but for the purpose of blending the mixture more thoroughly it is ground between rollers, and is afterwards forced by means of a powerful press through the interstices of a finely-woven wire sieve, thereby removing any impurities or undissolved particles of xyloidine. After passing through the sieve, it is mixed with the requisite quantity of oil and the particular pigment necessary to make it suitable for the purpose for which it is intended, and taken to a heated masticator, where it is kneaded to the desired consistency, and is then rolled into sheets by a powerful calendering machine, after which these sheets are submitted to a heat of between 100° and 120° Fahr. for a period varying from two weeks to a month. If the xylonite is required to become hard during this seasoning process, it is necessary to use an oxidized oil, such as linseed-oil, in its preparation, whereas the flexible kinds are produced by the employment of cotton-seed or castor-oil.

It will be seen that any tint can be given to this material by incorporating with it a pigment of the desired colour; but in preparing non-actinic sheets for photographic purposes semi-transparent colours only are used, such as will arrest the passage of chemical rays and furnish a material for the window of the dark room in place of the ordinary yellow glass. Indeed, there is little doubt that this substance will be largely employed in the manufacture of the apparatus employed in the art of photography—*e.g.*, for baths, dippers, and dishes for development, &c.; and Mr. D. Spill, in a paper read before the Photographic Society, thinks he may succeed in adapting it as a substitute for glass in taking negatives. It is also thought that by its means bisulphide of carbon may be converted into a viscid, colourless, transparent liquid without material dilution or reduction of its refractive index, which, if accomplished, would render the bisulphide of great value to opticians for use in compound lenses and prisms. One of the applications of xylonite consists in waterproofing fabrics, for which purpose it is applied in a semi-fluid condition with an ordinary india-rubber spreading machine, or sheets can be made to adhere to the substance to be coated by passing both through the rollers of a calendering press. It can be turned in a lathe, or wrought by the brass-finisher's or cabinet-maker's tools, embossed or moulded by heat and pressure, and is capable of taking a high degree of polish. It is unaffected in the finished state by heat, water, grease, or atmospheric influences; and has already been applied to various purposes by the Xylonite Company (who possess all the patent rights), such, *e.g.*, as the insulation and protection of telegraph wire, making artificial leather, writing tablets, bearings for machinery, friction and gear wheels, organ and pianoforte keys, billiard balls, umbrella and walking-stick handles, &c.

The xyloidine produced in the first stage of the manufacture is in reality a gun-cotton, but of the lowest possible degree of nitration, burning very slowly, and leaving a considerable amount of carbonaceous residue. As previously remarked, the articles of commerce to which this preparation is applicable are already too numerous to mention, and there can be little doubt, we think, taking into consideration the great improvements introduced into its manufacture of late years, that it will ultimately become one of the most useful materials with which we are acquainted.

Building Intelligence.

CHURCHES AND CHAPELS.

NEW REREDOS AT S. ASAPH CATHEDRAL.—The erection of a magnificent reredos, presented by Mrs. Hesketh, of Gwrych Castle, has now fully completed the ornamentation of the choir and chancel of S. Asaph's Cathedral. The design is by Mr. G. Gilbert Scott, R.A., and the sculpturing by Mr. Earp, of London. It consists of an entablature in alabaster, with arcading on either side. The sculpturing which adorns the entablature represents the procession to the place of crucifixion. In the centre, which is surmounted by a dome terminating upwards in a pinnacle of rich tabernacle work, is the figure of Christ bearing the cross; to the right are Roman soldiers preceding, and on the left the three Marys and several of the disciples following. All these figures are in *alto relievo*, appearing at first sight to be altogether detached from the background; but behind the effigy of the Saviour a Roman centurian on horseback is delineated in *bas relief*. The arcading is of a handsomely decorated Gothic style, the massive capitals being supported on polished marble pillars. The cost of the reredos is about £600.

SOUTHPORT.—The new church of All Saints, Southport, was opened on Thursday, the 5th inst. The edifice is in the Early Decorated style of architecture, and the dimensions are as follows:—Length, 73ft. and width 42ft.; chancel, 25ft. by 20ft.; height to the ceiling line, about 34ft.; and belfry with spirelet, height 90ft. All the windows are in tracery. The exterior is faced with stone throughout. The church is intended in the first instance to seat 500 worshippers. Mr. J. Sidebotham, of Lord-street, is the architect, and Messrs. Wishart & Irving the contractors.

WARRINGTON, LANCASHIRE.—The new Baptist chapel in Legh-street was opened on January 5. The site of the former chapel in Bewsey-street, having been bought by the Great Northern and Midland Railway Companies for the use of their new line from Liverpool to Manchester, it necessitated a new one being built, and as the whole of the material remained in the hands of the trustees, the new one has, to a great extent, been built with it. The architect, however, has remodelled the front entirely; it is now of pressed brickwork, with Cefn stone jambs, arches, and labels, to windows and doors; pillars of red Mansfield stone and red granite, with carved foliated caps. The entrance door has over it a carved panel with the vine, passion-flower, and wheat, interwoven with a ribbon, which bears the name of the chapel. The carving has been executed by Mr. Bate, of Manchester; the building by Messrs. Gibson & Son, from the designs and under the superintendence of the architect, Mr. William Owen, jun., of Warrington.

INCORPORATED CHURCH BUILDING SOCIETY.—This society held its usual monthly meeting on Monday last, at the society's house, 7, Whitehall, S.W., the Earl of Romney in the chair. Grants of money were made in aid of the following objects:—Building new churches at Eley, in the parish of Caerau, near Cardiff, and Newark St. Leonard's, Notts; enlarging or otherwise increasing the accommodation in the churches at Canterbury S. George; Catterick, Yorkshire; and Dunton, near Winslow, Bucks; under very urgent circumstances additional grants were made towards building a church at Nottingham S. Andrew's, and from the special fund towards building a mission church at Rhwsfa, in the parish of Nantmel, Radnorshire. A grant was also made from the School-church and Mission-house Fund towards building a school-church at Harrowbarrow, in the parish of Calstock, Cornwall. The society likewise accepted the trust of sums of money as repair funds for the churches at Burton-in-Lonsdale, Yorkshire, and South Kensington S. Stephen's, Middlesex.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

To OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—H. J. P., S H. & Co., H. J. F. K., W. S., W. B., P. W., S. & Sons, J. H. T., W. W., H. J., T. P., P. Bros., A. H., J. H., W. B., Enquirer, W. E. L., S. E. B., W. & B.

J. L. T.—Ask through "Intercommunication."

H. K. GRIBBLE.—Sketches returned.

D. GRANT.—Sketch returned.

P. AULD.—The addition came to hand.

GEO. HOLFORD.—The sedilia will appear. Please send a few words of description.

THOMAS JEFFREY.—Sketch long since returned.

C. H. T.—Let us finish one sketch-book before we talk about another. When the first is finished and the prizes awarded and distributed, we shall have another suggestion to make.

G. S. A.—Covers 2s. each; volumes bound for 3s. 6d.

Correspondence.

ALBERT DÜRER.

(*To the Editor of the* BUILDING NEWS.)

SIR,—I am very glad to learn that you intend to reproduce by our photo-lithography the works of Albert Dürer. I have read much about the great German engraver, and have seen a few of his wonderful works, and should very much like to possess some of them. But next to possessing the engravings themselves, which are now very rare, and consequently very valuable, I should esteem it a great privilege to possess exact reproductions of them, and now hope to do so through the BUILDING NEWS. I shall look forth with great interest for the publication of the series you have promised, and I should think thousands of others will do the same, considering the fame of the artist, and the value of his productions.—I am, &c.,

A COUNTRY SUBSCRIBER.

UNGRACIOUS.

SIR,—In conning over late numbers of your journal I found a great many queries unanswered in "Intercommunication"; I send replies to some of them. The notice I lately sent you of Elvedon was made extensive use of by the press, metropolitan and provincial, but none had the grace to say where they got the information. Amongst the offenders the *Builder* is prominent.

—I am &c., P. E. MASEY.

24, Old Bond-street, Jan. 17.

PAYMENT OF ARCHITECTS BY PERCENTAGE.

SIR,—In the BUILDING NEWS of December 30, there was a letter on the subject of payment of architects by percentage, from Mr. E. L. Garbett, in which the following passage occurred:—"Your correspondent talks of the 'loss and degradation it involves,' and I have just the same language in a letter received from Mr. Geo. Edmund Street some years ago. Of course I immediately asked, as I now must again, 'Degradation? By whom? Who, then, degraded you, sir? Who requires you to take percentage on an outlay?' No answer have I got from my friend to this day. Now I publicly challenge these two men who write, one publicly and the other to me, that they have been 'degraded,' to name their degraders."

When I read this passage I was, I confess, considerably astonished. I never to my knowledge saw Mr. Garbett, and I certainly have not the honour of his acquaintance. I remember some years ago that he did write to me and I to him on the subject of the payment of architects. I feel perfectly certain that I never said or implied that I felt myself in the least degree degraded by accepting the established custom, for I have never felt anything of the sort. I wrote at once, therefore, to ask Mr. Garbett to be so good as to send me a copy of the letter from which he quoted. In reply, he tells me that he will send it whenever he can "turn it up;" and that he has not seen it for two years, but knows "that its expressions resemble Mr. Aitchison's"!

I have waited since the receipt of this reply (January 5th) to give Mr. Garbett a fair chance of finding my letter, and substantiating his statement. As, however, he has not done so, I am obliged, in justice to myself, to say that I feel sure he has misquoted me altogether. I *may* have said that the payment by percentage is an absurd custom, because good work and bad work, easy work and troublesome work, are all paid for at the same indiscriminating rate. But absurd rules do not seem to me to be of necessity degrading, and I have never suspected myself of being degraded by acting on this particular rule, and I never, to the best of my belief, received any letter from Mr. Garbett asking the question which he says he at once asked on this point.

In conclusion, I may say that I think the publication of paragraphs from private letters is not a custom which can be justified, even where the letters themselves are really and fairly quoted; and that Mr. Garbett's scheme for charging 10s. a square for the floors of every house he designs is considerably more absurd than, and leaves just as much opening for dishonourable practice as, the system of percentage on cost.—I am, &c. GEORGE EDMUND STREET.

Jan. 17, 1871.

KITCHEN BOILERS AGAIN.

SIR,—So frequent have been the accidents caused by the exploding of kitchen boilers, and so numerous the remedies advocated in the *Times* and other papers to prevent such a serious catastrophe, that I, for one, feel quite at a loss which plan to adopt to ensure perfect safety. One gentleman says:—Put a gas stove close to the cold-water cistern, to keep it from freezing, the heat to be regulated by the severity of the frost. Another says: Connect a large waste pipe to the bottom of main cistern, to enable you, at the first sign of a pipe giving way by frost, to let the whole of the water out of the house; I don't see how this will prevent the boiler exploding, if the pipes connecting the boiler and circulating cisterns are previously full of water, and frozen up. Another plan advised is to wrap the whole of the pipes and cisterns with felt; this appears to me to be the most sensible, especially where the pipes and cisterns are placed near the external walls, but, is the wrapping of pipes with felt absolutely necessary when the pipes are 5ft. from the external wall?

On my works, two practically experienced tradesmen are divided in opinion on the matter; therefore, to enable those who really do know to give me and others the benefit of their practical knowledge, I will state the different positions occupied by the main cistern, circulating cisterns, and kitchen boiler. The main cistern is of slate and fixed in the roof, directly over W.Cs. The circulating cisterns are over the bath, about 18ft. distant and 3ft. below main cistern. The kitchen boiler at back of kitchen range (which is fixed in an external wall), is about 45ft. from circulating cisterns, and 18ft. below; the pipes connecting these two points are quite 5ft. from any exterior face. The person connected with the kitchen range and boiler contends that it will not be safe unless the pipes and cisterns are wrapped with two thicknesses of felt throughout, saying that the cold from the brick wall will very materially affect the lead pipes in frosty weather. The plumber says that to wrap the pipes with felt would be a waste of time and felt, as they are carried along an internal wall, 25ft. of which is really in the kitchen, where he contends it will generally be moderately warm. He advises the hot-water cistern to be lined with felt, not to keep the cistern hot, but to prevent the heat from the cistern damaging the wood lining around cistern. For the benefit of myself, and I have no doubt others, I kindly solicit the experienced opinions of your numerous readers.—I am, &c.,

J. W. RANDLE.

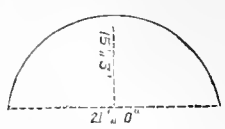
TENDERING FOR WEDNESBURY TOWN-HALL

SIR,—Referring again to this matter, your readers will remember that both Wednesbury architects received the first and second premiums in competition of over twenty. Notwithstanding the express stipulation by the Board that the cost was not to exceed £2,000, I find on Monday last the Board decided to accept the tender of Mr. Moore at £2,325, after the same had been cut down to the extent of £600 without violating the integrity of the building and affecting its utility. Comment further on this competition would be useless; when will this jobbery end?—I am, Sir, &c. OBSERVER.

Intercommunication.

QUESTIONS.

[2097] TUNNEL EXCAVATIONS.—Will some obliging reader furnish me with necessary information for calculating contents of tunnel where the chord and versed sine alone are given? For instance, what is the area of a tunnel or segment of a circle whose chord is 21ft., and height or versed sine 15ft. 3in.; also if in calculating for miners' measurement the plan area of tunnel is taken, or is any allowance made for excavation necessary to build brick arch beyond the height given, 15ft. 3in.?—SURVEYOR.



[2098] SPEAKING TUBES.—I want to use a speaking tube between a mansion and the stables belonging thereto; the distance is about four hundred yards; the course of the tube would be nearly straight, so that angles and sharp curves would be avoided. If some one who has had experience in long tubes could give me a little information it would greatly oblige.—H. H.

[2099] REMOUNTING PHOTOGRAPHS.—I have a fine set of architectural photographs, but the boards they are mounted on have got soiled. Can any one tell me how to remove these photos without damage?—GEORGE A. NOBLE.

[2100] TAYLOR'S PATENT TILING.—I should be glad to have the opinion of one who has used the above as to the capabilities in keeping out wet and withstanding high winds. I used them on one occasion and found they did neither satisfactorily, but was told by the manufacturers that it was owing to their being improperly laid.—TEGULA.

[2101] QUICK DRYING PAINT.—I should be glad to obtain any information as to the efficacy and durability of the quick drying paint lately advertised.—Z.

[2102] PIPES AND SMOKE FLUES.—Having heard a variety of statements as to the use of pipes and smoke flues, I am desirous of obtaining information from some one having practical experience in the use thereof. Are they liable to break from unequal expansion with the surrounding brickwork? If there is no objection to their use, what is the best description for the purpose—fireclay or glazed sanitary ware?—Z.

[2103] PLUGS FOR KITCHEN BOILERS.—Do the fusible plugs for kitchen boilers really answer in preventing explosion? or is the cause of accidents to be attributed to undue pressure on the boiler from the frozen pipes not leaving room for expansion?—Z.

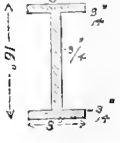
[2104] TEMPERATURE OF DAIRIES.—Will any subscriber oblige by informing me what means are employed in a good Cheshire or other dairy for regulating and maintaining the necessary temperature, and what generally are the principal points sought for, and how such are obtained in the construction of a large cheese dairy?—W. W.

[2105] HEATING ENTRANCE HALL.—Will any of your readers kindly inform me the best method of heating an entrance hall with hot air? A china pantry and larder occupy the space below the hall on the basement.—A. L.

[2106] THICKNESS OF WALLS OF CHURCH TOWERS.—In Gwilt, page 961, it says "The mean internal area should be half the external area." Does this mean that the product of the outside dimensions should be twice the product of the internal dimensions, or that the area of the floor should be half the area of the walls?—PUZZLED.

[2107.]—PLANS OF STATIONS.—Would some one kindly inform me where I could procure plans and geometrical elevations of the following railway stations:—Midland, Cannon-street, Charing Cross, Great Western, Broad street, and North Western?—WM. READ.

[2108] STRENGTH OF GIRDER.—Would some able reader kindly give the method of calculating the safe load that may be applied to a cast-iron girder 20ft. long, of the following section, and what allowance should be made if the web be openwork? Also the method of calculating the strain on web of wrought-iron girders?—W. F. T.



REPLIES.

[1996] UNANSWERED QUERY.—The lead used by glaziers for church windows has been used for the purpose, also clay, but if great accuracy is required there is nothing equal to careful sketching and measurement.—P. E. M.

[2015] PLANS OF COTTAGES.—Plans of cottages, with specifications, &c., are published by the Society for Improving the Condition of the Labouring Classes, 21, Exeter Hall, Strand.—P. E. M.

[2027] SCAGLIOLI.—Most works on architecture and building give description of this kind of work, for instance Nicholson's "Encyclopædia of Architecture," and Gwilt's ditto.—P. E. M.

[2044] CHANCEL WALL AND ARCH.—I am not aware of any law having been laid down on this point, but I should say that the duty of repairing the chancel arch rested with those who repaired the church. The wall belongs to the nave; it finishes the nave roof at a higher level than the chancel.—P. E. M.

[2045] CHURCH BUILDING.—It would be very unusual to have two arches at entrance of transept, and awkward, as the pier would stand in the gangway. The usual plan is to have one arch, making the last bay of nave coincide with the width of transept by widening the arch and its pier. Openings, more or less corresponding with clerestory windows, are sometimes left between transept and nave.—P. E. M.

[2062] ORIGIN OF PULPITS.—As the question of "S. H." refers to mediæval usage, and has not been completely answered, I beg to say that though pulpits exist in abbey refectories of date as early as the thirteenth century, they did not make their appearance in churches till the fifteenth century, and then were not common. Under the Reformation all churches were required to have them, hence so many of Jacobean date.—P. E. M.

[2068] SEVENTEENTH AND EIGHTEENTH CENTURY ARCHITECTURE.—Richardson's.—P. E. M.

[2075.]—TO PRACTICAL CLERKS OF WORKS.—In reply to "Old Foreman's" questions of December 23, as to walls built 2ft. 9in. thick, with 7in. of brickwork inside, I should think that he must be well aware that brickwork does not settle near so much as flintwork, especially if flints are small or rustic faced. The following I have found to be an average settling of brick and flintwork, taking the building to be of 50ft. in height. In every 1oft. of brickwork the settling will be 1in., and of flintwork, with rustic or rubble-faced, will be 1½in., if built in dry weather; consequently if stone quoins are not well tied in position they will be a little displaced by the outward tendency of flintwork. Probably "Old Foreman" is deficient of iron ties or bond of any kind, or he may not be seeking information but confirmatory evidence as to his own views, having a yoke of some inexperienced clerk of works cast on his shoulders, which I regret to say, from experience, is too often the case. Many rise to that position that can neither tell Portland stone from York, or a kiln brick from a burnt one, or Memel timber from Swede, to the great annoyance of foreman and loss to builder, besides a disgrace to surveyor or architect. This needs a thorough determination by architects or combination of builders throughout England to root them out. No doubt many of them may do well in their places as copying clerks in an architect's office, being able to use the pen neatly and quickly, but at all practical points they are entirely minus, yet treat those from whom they may glean with contempt. I apologise for thus intruding.—X. Y. Z.

[2077] FONTS—LEICESTERSHIRE, YORKSHIRE.—The font in Barrow Church, Leicestershire, is of thirteenth century date. That of Patrington, Yorkshire, fourteenth century. It is very unlikely there are two good Perpendicular fonts in Leicestershire.—P. E. M.

[2083] HIGGS' PROCESS.—This process of treating sewage is by adding milk of lime to the sewage as it enters the subsiding tanks, the lime precipitating all the suspended and part of the soluble matter. The solids thus obtained were formerly made into bricks, dried and sold to the farmers for manure. No town that I am aware of now manufactures these bricks, but this system of deodorising is carried on at works of which I have the management, and I should be glad to give "G. W. M." an order to view if he will favour me with his card.—THOS. W. GRINDLE, Borough Engineer's Office, Hertford.

[2087] ASPHALTE IN CHEAPSIDE.—The asphalte used is that of the Val de Travers, and is said to be better than the Seyssel, as containing more bitumen. There is nothing added to the natural material. It is simply ground, heated and applied.—P. E. M.

[2089.] — QUANTITIES.—In answer to "Justitia's" interrogatory last week, I beg to say that, as far as my experience goes, in connection with parish and corporation contracts, it is the custom of quantity surveyors to charge their commission (1, 1½, or 2 per cent., according to circumstances) to the successful competitors only; but, I am bound to state that not one penny comes out of his pocket, as the whole amount is always added to the tender (in one contract no less a sum than £600 was thus imposed on the ratepayers of the district), which is a most iniquitous thing, I consider, because the surveyors in the pay of the parishioners ought to prepare the bills of quantities themselves. Respecting private contracts, where no permanent engagement is given to architects or surveyors, although the treatment of the quantity surveyor's charges is precisely the same as in parish contracts, there are certainly some justifiable grounds for making the proprietor or owner of the contemplated works bear the charges for quantities; but, at the same time, I cannot refrain from saying that the general rates of charges are excessive in the extreme, and ought to be greatly reduced. In no case should several quantity surveyors be permitted to supply bills for the same job; such a practice is fraught with mischief, and is injurious alike to owners and contractors. —J. M. L., Battersea.

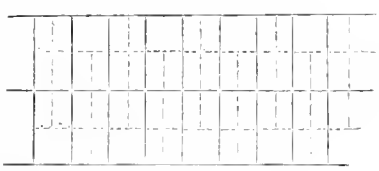
[2089] QUANTITIES.—In answer to "Justitia's" question I would answer 1st, that it is not a custom with many architects or surveyors to charge their bills of quantities against the competing contractors and in the few cases where it is the rule the money is refunded to all those who lodge tenders. 2nd, in cases where the contractors do pay for the quantities and do not get their money back the charge is understood to cover the surveyor's full commission, and the client will have nothing further to pay, unless he is foolish enough to pay twice for the same thing, seeing he indirectly pays the first, as the contractor must add whatever sum he has to pay for quantities to his estimate 3rd, the fairest way is to give the quantities free to the competing contractors, as they could not be expected to pay for quantities of work out of which they have no return. It would be a more reasonable scheme to propose paying all contractors who put themselves to the trouble of estimating for new work, seeing that to the unsuccessful it is labour (which is money) lost.—I. M. A.

[2089] QUANTITIES.—Customs vary with localities, and "Justitia" must at least name to what portion of England his queries apply before they can be answered satisfactorily. In many places contractors positively refuse to submit tenders unless quantities are supplied to them free of charge, and in others they have either to take their own quantities, or employ a surveyor to do so entirely at their own cost. It may be taken for granted that in the majority of localities the employer is the one who does pay, directly or indirectly, and who besides has such a right to the privilege? Quantities and contracting are absolutely inseparable; and, as the former is as essential to a building as the roof, should be paid for in like manner and by the same liquidator.—F.

[2091] CHURCH SITTINGS.—Seats or pews should be from 30in. to 33in. wide in the clear; seats from 12in. to 14in. in width, and from 13in. to 20in. of the seat should be apportioned to each adult sitter; the maximum or minimum being governed or regulated by the amount of available space and money, or other special restrictions or requirements.—F.

[2091] CHURCH SITTINGS.—According to the rules of the Incorporated Church Building Society, and generally followed, the width allowed to each person is 20in., the backs of seats being from 2ft. 8in. to 3ft. apart from centre to centre.—P. E. M.

[2092] BOND IN BRICKWORK.—The best way to bond 18in. work in old English would be thus:



the dotted lines show upper course.—P. E. M.

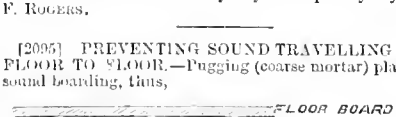
[2094.]—MEASURING STRING-BOARDS TO STAIRS.—"A Joiner's Apprentice" will find that a good method of doing this is to take the straight and circular wall strings separately, to their extreme length and width, and collect the cuttings, housings, and all other extras as they appear. The above is the method recommended in "Atchley's Price Book."—O. B. Q.

[2095] PREVENTING SOUND TRAVELLING FROM FLOOR TO FLOOR.—Use lime rubbish instead of sawdust. —P. E. M.

[2095.] — PREVENTING SOUND TRAVELLING FROM FLOOR TO FLOOR.—Fillets should be nailed about three inches down the joists to receive boarding, covered with one inch of coarse mortar. This should be done when the building is covered in, and remain some time to dry before the flooring boards are laid.—PUGGING.

[2095.] — PREVENTING SOUND TRAVELLING FROM FLOOR TO FLOOR.—I have found it very effectual to lath under the joists, on a pricking coat of lime and hair, and then put on ceiling joists, say 3in. by 2in., to which the plaster or boarded ceiling may be nailed. This not only keeps out the sound, but allows the timbers to be well ventilated, which is the only way to keep away dry rot.—F. ROGERS.

[2095] PREVENTING SOUND TRAVELLING FROM FLOOR TO FLOOR.—Pugging (coarse mortar) placed on sound boarding, thus,



is generally considered preventative.—F.

WATER SUPPLY AND SANITARY MATTERS.

DUNDEE.—A special meeting of the Dundee Water Commissioners was held on Monday evening last to consider the financial questions connected with the new water scheme. The Convener of the Works Committee explained that, calculating upon an increased rental of £16,000 yearly, and carrying out the works essential for the new scheme, and leaving the other portions unexecuted until the town grows larger, the scheme could be carried out without any increase on the present rates. The opinion was expressed during the discussion that as the Commissioners had obtained supplementary sources of supply for three years, and that the time might be further extended by agreement, there was not now such pressure upon them to enter upon the new scheme, and that, therefore, time should be taken to consider it in all its bearings. The matter is to be brought before the townspeople.

LAND AND BUILDING SOCIETIES.

ST. PHILIP'S BUILDING SOCIETY.—On Tuesday evening the 21st annual meeting in connection with the above-named society was held at Birmingham. The secretary (Mr. William Worrall) read the annual report, which, having traced the origin of the society and explained the way in which its business is conducted, claimed it to have been eminently useful to the class for whose benefit it was originally established, and pointed out the desirability on the part of the members of doing what they could to increase its strength, of maintaining its reputation, and of making it beneficial to the working classes. Up to the end of last year 702 shares had been taken, the receipts amounted to £4,158, the profits divided to £8,861, and the reserve fund to £1410.

TOTNES BUILDING COMPANY (LIMITED).—The annual general meeting of this company was held recently, and a dividend of 2½ per cent. was declared.

Our Office Table.

THE PROPOSED NEW ENGINEERING COLLEGE.—A deputation from University College, London, consisting of Mr. George Grote, the president, the Hon. George Denman, M.P., Mr. Julian Goldsmid, M.P., and Dr. Storrar, members of the Council; Professor Fuller, C.E., Professor Williamson, F.R.S., and Mr. J. Robson, the secretary, has waited upon the Duke of Argyll, at the India-office, to present a memorial from the Council and the Senate of the College, on the subject of the proposed institution of a new Engineering College for the Indian Service. The interview with his grace lasted upwards of an hour. The memorialists consider that the deficiency in the present system has arisen, not from any defect in the existing places of education, but from the injudicious system of examinations hitherto pursued, and from a want of sufficient inducements to well-qualified men to enter on the career proposed to them. The memorialists assume that the latter cause is recognised by the Government, for it is understood that it is in contemplation to augment considerably the salary upon which a civil engineer in the service of the Indian Government will hereafter commence his work. The memorialists believe the proposed college will be prejudicial to the public service by narrowing the field for the selection of candidates, and by limiting their means of obtaining the requisite instruction. They submit that the working of Government Colleges has not been such as to recommend the the creation of a new Government College, having practically the monopoly of appointments, and protected from competition. They suggest that such a step is at variance with the plan for throwing open to all her Majesty's subjects the opportunity of gaining Government appointments.

STREET TRAMWAYS.—Mr. John Noble recently read a paper at the rooms of the Social Science Association advocating the propriety of local governing bodies undertaking the construction of street tramways. He endeavoured to show that no apprehension need be felt that the tramways would prove a commercial failure, by quoting statistics in reference to similar undertakings in various cities of America, and urged the necessity of a Royal Commission being appointed to inquire into the subject. In the course of a discussion which followed the reading of the paper, Dr. Brewer, M.P., strongly objected either to the Government or the Board of Works undertaking the construction or working of street tramways. It was, he said, certainly not within the functions of the former, and while so much prejudice existed in the minds of the vestries against the introduction of tramways into the public thoroughfares, it would be unwise and unwarrantable for the Board of Works to undertake the task.

FIRE IN A CHURCH SPIRE.—On Saturday night, about nine o'clock, sparks were observed to be coming out of the top part of the spire of S. Saviour's Church, Bamber-bridge, near Preston, under which there is a flue, and as they continued to increase, it became quite apparent that there was something on fire in the building. A number of men proceeded to the church with ladders, &c., got up the tower, and on reaching the base of the spire found that the beams which are inserted for the purpose of strengthening the stonework, were all in flames. There was a very strong wind blowing from the west, and this fanned the flames considerably. The flames were got under. All the higher beams in the spire were burnt away, and some of the lower ones were damaged. The fire is supposed to have originated through the over-heating of the flue which runs through a portion of the spire.

HALIFAX SCHOOL OF ART.—On Friday evening the annual meeting was held at the Mechanics' Hall. Mr. H. C. McCrea (Mayor) presided, and the report stated the regular classes have maintained a good average attendance throughout the year, in marked contrast to previous years, when the attendance during the summer months had

always fallen off. One of the students, Mr. T. Holland, obtained a certificate of the third grade at the annual examinations held at South Kensington last February. This is the first third grade certificate obtained in this school. Two of the students, Mr. Drake and Mr. Smith, are now studying at South Kensington, having each obtained national scholarships of the annual value of £50. In this year's national competition one of the students, Mr. F. Spencer, obtained a silver medal for a design for "wall decoration." Mr. H. Robinson was awarded a bronze medal for "design for carpets." Three other students obtained prizes of books for successful elementary designs. The general results of the examinations were as follow:—1 third grade certificate, 1 national silver medal, 1 national bronze medal, 9 second grade prizes, 8 third grade prizes, 5 free studentships, 18 certificates in freehand, 23 certificates in model drawing, 3 certificates in perspective, 7 certificates in geometry, and 3 full certificates. The report was adopted, and the certificates and prizes having been presented to the successful students, an address on the "History of English Ornament" was delivered by Mr. R. R. Holmes.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—*Royal Institute of British Architects.*—"On the New Buildings for St. Thomas's Hospital." By Mr. H. Currey, F.R.I.B.A. 8 p.m.

TUESDAY.—*Institution of Civil Engineers.*—(1) Discussion on Mr. Browne's paper "On the Strength of Lock Gates." (2 "On Train Resistance on Railways." By Mr. W. Bridges Adams. 8 p.m.

WEDNESDAY.—*Society of Arts.*—"On new Paper-making Materials, and the Progress of the Paper Manufacture." By Mr. P. L. Simmonds. 8 p.m.

THURSDAY.—*Society for the Encouragement of the Fine Arts.*—"On Prehistoric Art." By Dr. G. G. Zerffi. 8.15 p.m.

FRIDAY.—*Architectural Association.*—"London as a Field of Study for an Architect." By Mr. T. Roger Smith, F.R.I.B.A. 7.30 p.m.

Chips.

New schools for the sons of poor clergymen are in course of erection at Leatherhead, Surrey, at an estimated cost of £12,500.

A large new model lodging-house is to be erected in Wigan-street, Silsbridge-lane, Bradford, under the auspices of the Bradford Model Lodging-house Company.

The first section of the new market at Newton Abbott, Devon, was opened last week.

Baylham parish church, Suffolk, was reopened on Friday, after extensive restorations. North and south transepts have been built, the old pews have been replaced by oak benches, the unsightly west gallery has been removed throwing open a handsome two-light west window, and a new stained glass three-light east window has been inserted in place of the old one. The mullions of all the windows, some of which were formerly of wood, have been removed and fresh ones inserted.

The Metropolitan Board of Works has forwarded a cheque for £2,100 to the S. Olave's District Board of Works, in aid of the cost of widening a portion of Tooley-street, Southwark.

Timber Trade Review.

PRICES, 17th January:—Grooved, tongued, and beaded flooring boards, per square.—Fir brickstadt 1st yellow, $\frac{3}{4}$in., 7*s* 3*d*; do. 1st white, $\frac{3}{4}$in., 6*s*; $\frac{1}{4}$in., 5*s* 3*d*; do. 2nd white, $1\frac{1}{4}$in., 7*s* 6*d*. Prepared flooring boards not grooved, &c.—Fredrickshald 1st white, 1in., 7*s* 6*d* to 9*s*; $\frac{3}{4}$in., 7*s*; do. 1st yellow, $1\frac{1}{4}$in., 13*s* 3*d*; 1in., 10*s* to 10*s* 3*d*; do. 2nd yellow, 1in., 7*s* 3*d* to 8*s*; $1\frac{1}{4}$in., 10*s*.

Deals, &c., per Petg. std.—Saguenay best bright yellow pine, 15*l* 10*s* to 15*l* 15*s*; do. mixed yellow, short lengths, 9*l* 15*s* to 11*l* 15*s*; do. 2nd bright, 11*l* 5*s* to 12*l* 15*s*; do. 3rd bright, 8*l* 5*s* to 9*l*; do. 4th bright, 11*l* 5*s* to 12*l* 15*s*.

Soderham mixed yellow, 9*l* 5*s*; do. 3rds, 8*l* 5*s*.

Quebec pine, 120 12ft. 3 × 11in.—1st bright, 19*l* to 19*l* 10*s*; 1st dry floated, 17*l*; 2nd dry floated, 12*l* 10*s*; 2nd floated, 12*l*; 3rd bright, 8*l* 15*s*; 3rd floated, 9*l*.

Petersburg 1st white, 7*l* 15*s* to 9*l* 15*s*; do. 2nd, 7*l* to 7*l* 10*d*; do. 1st yellow, 10*l* 5*s* to 11*l* 5*s*.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

WHITCHURCH, Feb 20.—For the erection of town-hall and markets in Whitchurch, Salop. Local Board Officer Whitchurch, Salop.

WHARFDALE UNION, Feb. 9.—For plans, specifications, and estimates for the erection of a new workhouse, to accommodate 150 inmates, exclusive of vagrants, on ground situate at Newhall, near Otley. C. J. Newstead, clerk to the guardians, Board-room, Boroughgate, Otley.

MUNICIPALITY OF COLOMBO, Jan. 31.—For the preparation and supply of the smith and founder's work required for the new public markets and municipal offices at Colombo, Ceylon. S. Grenier, secretary, M C., Colombo.

WAR DEPARTMENT CONTRACT, Feb 4.—For the necessary work and materials required in the performance of work and repairs, and supply of labour or materials separately, as required for the service of the War Department, to the buildings in the Permanent Barracks, camps, or property at Aldershott, and connected with the War Department property at or in the vicinity of Aldershott. Director of Contracts, War Office, Pall Mall.

HEREFORDSHIRE, Jan. 31.—For the erection of farmhouse at Hegdon Hill, near Bromyard, Herefordshire. Ernest A. Day, architect and surveyor, Foregate-street Worcester.

WAR OFFICE CONTRACT FOR TIMBER, Feb. 4.—For the supply of dry ash plank, of the very best and toughest quality, thoroughly seasoned. Forms of tender may be obtained from the Director of Contracts, War Office, Pall Mall, London.

LONDON AND BLACKWALL RAILWAY COMPANY, Jan. 24.—For brickwork, ironwork, earthwork, and other descriptions of work required for the construction of a part of the Millwall Extension Railway, about 650 yards long, near to the East Ferry-road and the side of the river Thames opposite to Greenwich Hospital. John F. Kennell, secretary, offices, London Terminus, Fenchurch-street, E.C.

LONDON (St. Luke's Workhouse), Jan. 25.—For the erection of a kitchen and offices at the St. Luke's Workhouse, City-road. James W. Hill, Clerk to the Guardians, Clerk's Offices, Workhouse, Gray's-inn-road.

POPLAR, Jan. 26.—For the erection of stabling at Brunswick street, Poplar, for the London General Omnibus Company (Limited). A. G. Church, general manager and secretary.

LEEDS, Feb. 2.—For the completion of a villa residence in Chapeltown-road. Alfred H. Thompson, architect, Park-square.

ESSEX, Jan. 25.—For the construction of an intercepting sewer, subsidence tanks, sand and earth filters, with aerating apparatus, embankments, labourer's cottage, and other works necessary for the purpose of dealing with the sewage of Buckhurst-hill, by means of intermittent filtration. William Hunt, Clerk to the Sewer Authority, Chigwell, Essex.

WHITCHURCH (Whitchurch Local Board), Feb. 20.—For the erection of town-hall and markets in Whitchurch, Salop. S. M. Lockwood, architect, 85, Foregate-street, Chester.

CARLISLE, Jan. 25.—For the building a church at Chalk Fell. Messrs Cory & Ferguson, architects, the Courts and Bank-street, Carlisle.

SOUTHEND LOCAL BOARD, Jan. 31.—For certain portions of the house drainage connections to the main sewers. W. Gregson, jun., clerk, Southend Local Board Office, Royal Hotel, Southend, Essex.

LEEDS, Jan. 27.—For the erection of six houses in Camp-road, Leeds. 64, Meanwood-road.

KENT (Coastguard Contract), Jan. 25.—For the erection of a coastguard station at Swale Cliff, Kent. Coastguard Watch-room, Whitstable.

BANKRUPTS.

(TO SURRENDER IN THE COUNTRY).

John Hughes, Liverpool, builder, Jan. 30, at Liverpool.—John Martin, Chatwell Court, late of S. George's, Salop, ironfounder, Jan. 30, at Stafford.—George Roots, Bradbourne, near Sevenoaks, brickmaker, Jan. 25, at Tonbridge Wells.—Henry Williams, Sedgley, firebrick manufacturer, Jan. 28, at Dudley.

PUBLIC EXAMINATIONS.—ACT, 1869.

Feb. 10, H. Driver, Lee, Kent, architect and builder.—Feb. 6, J. M. Edwards, Thornton Heath, builder.—Feb. 10, J. Harvey, Bristol, builder.—Feb. 22, G. Westcott, Saltash, slip builder.

DIVIDEND MEETINGS.

Feb. 25, J. Cutler, Bournemouth, builder.—Feb. 2, F. Parsley, Clevedon, Somerset, builder.—Feb. 15, T. Underwood, Abersychen, Monmouthshire, ironmonger.—Jan 26, M. A. Jones, Nelson-street, Rotherhithe, late timber dealer.—Jan. 27, J. Casbolt, Balsham, Cambridgeshire, bricklayer.—Jan. 27, T. V. Leverage, Cambridge, builder.

PARTNERSHIPS DISSOLVED.

Bolt & Co., Newport, Monmouth, builder.—Smith & Co., North Bierley, brick manufacturers.—Pritchard & Co., Llangollen, timber merchants.—Popes & Bindon, Bristol, architects.—Hall & Middleton, Harewood, Lancashire, contractors.

THE BUILDING NEWS.

LONDON, FRIDAY, JANUARY 27, 1871.

MONUMENTS OF ART.

I. PROLEGOMENON.—In order to study the history of works of art with real advantage, it is above all necessary to make ourselves acquainted with the geographical position of a country, the formation of its mountains, the flow of its rivers, and its connection with the sea. Next we have to consider its population from an ethnological point of view; then the religious, political, and social condition of its inhabitants. Art takes its origin in necessity, and in the cravings of our intellectual force to satisfy the demands of necessity. Necessity is created by the influences of climate and soil. Our intellectual power is either developed or checked by our moral condition, of which religion and the political and social state of a people form the basis. Art cannot be studied one-sidedly. If studied so, it remains for ever a mere product of chance. But art is subject to firm, cosmogonical laws; in studying the history of art we have to trace the working of these laws, and to find out the causes why art should have succeeded under certain conditions, and why it should have remained stationary or failed altogether under others. In tracing art to its forms at different periods of the historical condition of mankind, we become conscious of its gradual growth, and of the causes which promoted that growth. In describing the plates, which are photo-lithographic reproductions of the great German Historical Atlas of Art, which has reached a second edition,* I shall briefly point out the causes which produced certain forms of art, note the influences on the productions of other nations, draw analogies, and dwell on the connecting links between the artistic forms of one nation and another. Art, in its actual state, is the sum total of previous products, only in different combinations.

II.—BABYLON AND NINEVEH.—The alluvial valley of the Euphrates and Tigris was undoubtedly the seat of a most ancient civilisation. Correct dates are wanting. The forms of art of the Babylonians and Assyrians afford a proof that the nomadic element was prevalent with them even after they distinguished themselves by brilliant deeds in war, an extended commerce, and many valuable products in the arts of peace. The valley of the two rivers, with its connection with the Persian Gulf, was early the high road of commerce, the link between India, Central and Northern Asia, and even Europe. The Babylonians, Assyrians, and Persians were Aryans. Their language rooted in the Zend, their mode of writing was the cuneiform. Their works of architecture and sculpture, their textile fabrics, furniture, and mode of ornamentation were analogous. All this points to a similarity of social and political conditions. In all their works of art the lay element predominates. The king or ruler, with his deeds in warfare or at the hunt, in the banquetting hall or in offering sacrifices, is the principal figure. We have with them traces of huge towns and palaces, but scarcely any temples. The so-called Temple of Baal or Belus (Helios, the sun) was most probably an astronomical observatory. Their sculpture is full of vigour and life, but it bears all the marks of a state of transition from savage art to that of the warfaring nomad. The oldest remains of Babylonish and Assyrian art are found in the most southern part of the great group explored by Mr. Layard and M. Botta. Here we have the Birs (Burg) Nimroud, and in a north-western corner a terraced pyramid 150ft. at the base, supposed to have been the tomb of Sardanapalus or Ninus. On the Tigris, in a northern direction, we have the ruins of Nineveh, Khorsabad, and Kouyundjik. The buildings were all terraced. The rooms surrounding the courtyards were narrow and long, the walls generally of sun-dried bricks, and from 7ft. to 17ft. thick; they are only preserved in their lower parts, showing no traces of architectonic divisions. They were covered throughout their whole length with thin slabs of sandstone or alabaster, to a height of from 8ft. to 10ft. Above them a frieze of coloured and glazed tiles seems to have completed the wall. What the ceilings and inner divisions were can only be surmised. In the sculpture of Assyria, as well as Babylon, there is very little of symbolism. With the exception of some eagle-headed priests, and some lions or bulls with human heads and wings, we have only scenes of a general character. The reliefs are executed like those of Egypt; but Egyptian sculpture has somewhat of a settled style, is made according to a certain canon, and this is the principal reason that modern historians of art like Dr. Semper suggest the idea that Assyrian sculpture, with its unsettled but freer treatment, its sharp, rope-like muscles, and passive anatomy, must be of an older period than that of Egypt—though we cannot deny that hair and beards are treated with a kind of conventional stiffness.

Fig. 1 of our lithographic plate represents a symbolic, whimsical being with four wings; it was found at the façades of the entrance gate at Khorsabad (see "Le monument de Ninivé decouvert and décrit par M. F. S. Botta, mesuré et dessiné par M. E. Flandin." Paris, 1849). The double pair of wings reminds us of the cherubims of the Jews, with their four wings and four faces: the face of a man, the face of a lion, the face of an ox, and the face of an eagle. The head of our figure is covered with a tiara adorned with horns. These horns are equally found on Egyptian and Hebrew head-dresses, and seem to have been the distinguishing symbol of the priests. The under-dress reaches to the knees, and is adorned with fringes, as also the upper-dress; both are very much like the officiating dresses of the Greek clergy of the present day. In his right hand he holds a pine-apple, or rather sacrificial cake; in his left he holds a basket or vessel with the juice of the sacred tree, the gaokerena, the fruit of which is the white haoma (with the Indians, "soma"), for the Zend people had also two sacred trees: the gaokerena and the painless tree. Bracelets and ear-rings show that personal ornamentation had already reached a high state of elegance.

Figs. 2 and 3 are men with lions. Hair and beards treated in the usual conventional, curly manner. The head-cover is wanting. The first figure is like that previously mentioned, as far as dress goes. The second is without the upper-dress and without sandals, and the hair falls down in long and single curls. Both are placed between winged bulls (see Fig. 7), and are above the usual size, and alike in position and action. As in Egyptian reliefs, their heads and breasts are in front, whilst the legs are in profile. This mistake is often observed in saints of the early Christian sculpture. Both figures hold in their left arms a lion, which they press vigorously to their bodies; the animals appear to object to this treatment, and their resistance is well expressed in the ferocious look, the open claws, and the curled tail. In their right hands they hold a kind of whip, ending at the handle in an animal's head, very much like that of a serpent.

Fig. 4. is a winged human being with a bird's head, from a gate at Khorsabad. The back figure, in dress, position, and expression has great resemblance to the figure in No. 1, but has no sandals, and the head is covered with a diadem instead of a tiara. The other figure in the foreground is, with regard to dress and position, also like No. 1. There is only one pair of wings, and the head is covered with a mask, representing an eagle's head. Our savages, the Mexicans of ancient times, the Greeks, Egyptians, Romans, the old Teutons, in fact nearly all nations, used to wear on solemn occasions, at religious or other festivities, masks of animals, so as to show their dignity by a frightful outer appearance. Why not the Assyrians too? Some strings and tassels, and a kind of ornamental pin fastening the mask under the chin, strengthen my opinion that the head of the eagle was a mere head-dress, out of which, later, helmets with their crests were developed.

Fig. 5, eunuchs carrying a chair, the men richly dressed, but without beards; the chair sumptuously adorned with sculptures—its legs ending in the shape of a pine-cone—on the back a small human figure is carved. We may in these forms especially observe the great contrast between Assyrian and Egyptian sculpture. In the latter the figures were drawn thinly and delicately, whilst in the former strong, round, and muscular forms predominate.

Fig. 6, "king hunting a lion" (Nimroud). The king may be recognised by his head-dress, the ends of the band hanging down his back. The king is accompanied by his charioteer. The lion pierced with three arrows breaks down roaring. Out of respect for the king's face the bow-string is interrupted where it ought to cross his person. This small, apparently unimportant, incident shows us that real art is impossible whenever despotism rules supreme. The horses are profusely decorated with strings and tassels. From the chariot hang quiver and arrows, and the battle-axe, all richly ornamented.

Fig. 7, winged bull with human head (Khorsabad). The entrance gates were adorned with such colossal sphinx-like animal, symbolically expressing the power of the ruler. Strong he was and mighty, like a bull or lion; swift in his reward and punishment, as an eagle; and wise and just, like a perfect human being, at least, ought to be.

Fig. 8, king on his throne (Nimroud). In pompous robes, with the tiara and the floating ribbons, sitting on a splendid chair, we behold the ruler of the Assyrians. In his right hand he holds a cup. Before him stands a eunuch, with a fan in one hand and a saucer in the other. Behind him appear two other eunuchs with fans. On both sides we have a bearded figure like that in Fig. 1, only the wings are missing, probably for want of space. Neither Assyrians nor Egyptians ever troubled themselves much about the principles of symmetry.

Fig. 9. siege of a fortress (Khorsabad). In one of the narrow halls, about 114ft. long and 29ft. broad, the walls were adorned with two rows of reliefs, interrupted by a frieze of cuneiform inscriptions. The upper row represents a festivity. Eating and drinking were two of the most important occupations of despotic Orientals. Proof, the many excellent gold and silver drinking cups of exquisite workmanship. We recognise in this propensity the characteristic of the Aryan race. The row below represents the siege of a fortress by the Assyrians. The besieged are *in extremis*—they already lift up their arms anxiously begging for mercy; they are probably some half-savage Turanians with skin dresses and square shields, whilst the besiegers are distinguished by beak crests on their helmets and round shields. The portal of the fortress is arched, showing that the Assyrians were acquainted with the construction of the arch.

Fig. 10, fight, and festive dinner (Khorsabad). The king in his chariot is about to let fly an arrow. His charioteer and an attendant protect him with their shields. The enemies are dressed like those in Fig. 9, and are partly flying, partly killed. The upper division is filled with the representation of a banquet. Armed servants hold drinking vessels, others fans; guests are sitting on chairs in pairs, with goblets in their hands.

Fig. 11, passing over a river (Nim-

* "Denkmäler der Kunst." Stuttgard: Verlag von Ebner and Jeubert. 1858. London: A. Siegle, 110, Leadenhall-street.

roud.) The king is seen sitting in a boat with two of his attendants drawn by two men; others are seated at the oars. The chariot of the king is in the boat, bow and stern of which are alike. The horses are tied with ropes to the boat and swim after it, as also a man, supported by an inflated skin.

Fig. 12, hunt and target shooting (Khorsabad). Hall VII., had also two rows of reliefs; the upper row was devoted to the representation of a banquet, the lower to hunting and shooting scenes. The execution is extremely childish. Trees with birds sitting on them are meant for a forest. A bird pierced by an arrow is in the act of falling—others are flying about. A young man is trying his skill by shooting at a target; his bearded attendant minds a horse and holds a hare in his hand.

All these reliefs are full of naturalness and keen observation, as far as the reproduction of animal life is concerned. The human figure is stiff, very much resembling the statuary of Early Christian art. We have on the long walls of the Assyrians historical records in stone, executed in the manner of tapestry. Their ornamentation is decidedly a reproduction of harsh embroidery. We may trace in Assyrian and Babylonish art two periods of development. We have sun-dried bricks and burnt bricks. We have coarser outlines and stronger muscles, and a more refined and delicate treatment of the human form. We have a simple life and a life full of refinement, with a complicated social condition. Their architecture bears everywhere the traces of wood construction later executed in stone. In their smaller plastic works, in specimens of which the British Museum is one of the richest in the world, we may see the traces of foreign influences. But this was the case at all periods of ancient and modern times from Nineveh to Athens and Byzance, from Thebes to modern Parisian art; whilst the monumental products preserve their peculiarity and distinctive national features, the movable products are subject to all sorts of influences, and they do not authorise us to draw over-hasty conclusions as to the priority of any style. We shall find a third period of development of Assyrian art amongst the Persians.

G. G. Zerffi.

THE CHURCHES OF LINDISFARNE.*

(*Continued from page* 16.)

In the rural deanery of Norham we have the priory church of Lindisfarne, on the Holy Island, which is distant about two miles from the main land. In the days of Bishop Carileph, Edward commenced his great plan, forming the nave 100ft. long, 44ft. wide, the length of the apsidal-ended chancel being 35ft.; the transepts were 62ft. by 17ft., with an eastern apse to each, and he brought masons with him from Durham to carry out his designs. Mr. Wilson waxes eloquent, almost too much so, while giving reins to his imagination as to the operation that ensued. "Whether the sea lapped or leaped against the island; whether the waves came softly gliding along the shore, or wildly and wrathfully lashing it with scourges of spray and foam; whether the gracious sunshine almost transfigured the new work, or opal mists lightly veiled it, or chill sea fogs dreamily shrouded it, there were the clink, and clank, and chink of tools," &c. . . . "The sturdy columns, made winsome with dancette, chevron, and other ornament, rose higher and higher." . . . "Then crept and crossed the stalwart ribs over the aisles from pillar to responder;" "then grew the cunning vaulting," &c. "Labour is prayer, labour is praise, thought the masons." Well, we will hope they did, but we fear such fine writing is not to the taste of the present age, or that of our readers, and so we try to translate Mr. Wilson's poetry into plainer prose, and say that this chancel gave place to a longer one with rectangular end, built during the transition period between the Early English and Decorated styles. This new chancel was 50ft. long, and similar in that respect to the one that had previously been added to the parish church. Of this grand pile, now only ruins exist, and these are to be seen with their curious proximity to the Holy Island parish church (52ft. to rear of that building), reminding one of the dilapidated monster Temeraire following the puffing little tug-boat in Turner's picture, but we are indiscreetly lapsing into an imaginative vein ourselves, not certainly evoked by the charms of the blotted pen and ink drawing which forms the frontispiece of the volume before us.

Of the position of the parish church westward of the priory we have spoken; the bulk of it is Early English, though it contains also remains of Transitional Norman work, a portion of the north arcade with columns of red stone carrying arches of two chamfered orders, built with alternate vaussoirs of red and white stone, "an effective arrangement," says Mr. Wilson, "not found elsewhere in ancient work in the archdeaconry." The south arch and its arcade are Geometrical Decorated. The columns have no visible bases, and there are no labels to the arches. The church, the plan of which is a nave 56ft. by 19ft. 6in., with aisles, with porch to each, and chancel, 49ft. by 17ft., has been but indifferently "restored."

Ancroft is the only chapelry to Holy Island which has retained evidence of the character of the Norman fabrics which the monks reared in each of their chapelries on the mainland. They were content with a nave and chancel only. The latter has been unfortunately removed within the last few months to allow of an extension of the nave. A curious bell-tower was built in Edwardian times upon the west end of the church, three stories high, very sturdy and massive.

The church of S. Cuthbert, Norham, is mostly, as Mr. Wilson calls it, a very "noble, solemn, and reticent" Norman edifice; alas, however, with new aisles, tower and vestry. Originally the chancel was apsidal. The north arcade has octagonal and the south circular columns. On the south side of the chancel are still five rich Norman lights, high above the ground, with tall buttresses between each. On the north side the windows are, however, narrower and plainer. The chancel arch is of Norman work, wide, high and stately. On the north side of the chancel, close against the arch, low on the ground, are the remains of a small window, so splayed that it was possible for persons outside the church to see the rood-screen through it. A precisely similar window exists at Bothal Church. The stonework, scraped, is "of many tints."

In the village of Norham, on the banks of the Tweed, is a market-cross with ancient clustered base and six circular steps, and the grand old castle. The fortress of the Bishop of Durham is the pride of the neighbourhood.

The only other church in this deanery of the slightest architectural interest is that of S. Michael, Ford, within a walk of Flodden Field, and near to Ford Castle. The church, which Mr. Wilson alleges to have been faithfully restored, is Early English in style, consisting of nave with aisles with buttresses placed anglewise at the four angles; south porch, and chancel. An ancient and curious bell-turret surmounts the west end. It has openings for three bells, two below and one above, and is covered by a hipped roof.

The other fourteen churches in this rural deanery, though illustrated and described with equal elaboration, though perhaps less eloquence, are all modern structures of little or no value. The illustrations are not worth the paper they are printed upon, and the text which accompanies them only encumbers the work.

Out of seventeen churches in the rural deanery of Bamborough, all elaborately illustrated and described, only six are worth notice. The remainder are modern works, of which only one, that at Ellingham, is of respectable character; and that, with three or four more, have fragments of old buildings incorporated with them, and so far deserve to be chronicled. It is a strange omission that the names of the architects of the new and restored churches are never named, and this is to be regretted in such cases as those referred to with commendation. The pride of this rural deanery is the church of S. Aidan, Bamborough, rebuilt with much care, and in the best manner, in the Early English Lancet period; it is a large cruciform edifice possessing a fine west tower. It stands in an open position within view of the sea and of the noble castle. The chancel resembles those before described in point of length, and is lighted by couplets of lancets divided by buttresses on the outside, but joined together within by a rich continuous range of arches, producing a fine effect, and one that is partly characteristic of the work of this date in the locality. There is a crypt beneath the eastern portion of the chancel.

Old Bewick Church, a Norman building, is one of the four chapels that once belonged to Eglingham. In the Decorated period its apse was converted into a square end in a very curious manner by two clever and quaint pieces of corbelling between the round of the apse and two buttresses built at the angles for the purpose. This church has been recently and carefully restored.

Kirk Newton has a curious vaulted chancel, with the spring of the arch only 2ft. 9in. from the floor, and at right-angles with it a smaller chantry; and the contrast, says Mr. Wilson, between the modern lofty church and the low, stone-vaulted chancel, with its entrance like that of a cellar-door, is remarkable.

Chillingham Church, near Chillingham Castle, has Norman remains and a lordly altar-tomb of the Perpendicular period in the south aisle; and Duddington is an ancient Early English church with a curious plan—a long nave divided into two parts by a transverse arch in its centre, similar to the chancel arch.

These, with fragments of an old chapel at S. Cuthbert's, Farne Island, are the architectural treasures of the deanery of Bamborough.

The rural deanery of Rothbury has but little to boast of. Rothbury Church has a grand long chancel of Early English work; S. Michael's, Ingram, an ancient, massive, strong west tower, and remains of a larger, built incorporated with the present one. Whittingham has the famous Saxon tower figured in Rickman's work. S. Michael's, Alwinton, is an interesting structure of various dates, inclusive of Norman; and S. Cuthbert's, Elsdon, is a cruciform church of considerable interest and antiquity, with beautiful arcades of four arches and a fine five-light eats window; and S. Michael's, Alnham, completes the list of the churches of interest in this deanery.

The rural deanery of Alnwick is much richer than either of the last-named. S. Michael's, Alnwick, is a rich and spacious Perpendicular church with fragments of Norman work interwoven in its structure, with the chancel deflected considerably northward, and it contains five sculptured effigies. S. Lawrence, Warkworth, has a groined Norman chancel. S. James's, Shibotell, is a low, small Norman church; Lesbury is Early English; S. John Baptist's, Edlingham, is an example of the blending of military and ecclesiastical architecture, mainly Norman, as also is Rock Church; and Embleton and Long Houghton Churches are also ancient. But the Priory Church of SS. Peter and Paul, Brenckburn, is the boast, and deservedly so, of this rural deanery. It is Transitional, between Norman and English, in character, and it is now in course of restoration. Felton, Almworth, and

* "An Architectural Survey of the Churches in the Archdeaconry of Lindisfarne, in the County of Northumberland." By Frederick Richard Wilson, architect. Printed and photo-lithographed by M. & M. W. Lambert, Grey-street, Newcastle-upon-Tyne.

Long Framlington, are also of antiquity and interest.

The rural deanery of Morpeth contains the church of the Blessed Virgin at Morpeth, an ancient building of various dates, and the church of S. James the Great, a recent one from the designs of Mr. Ferrey.

The churches at Rothal, Widdrington, Whalton, Bolam, Meldon, Mitford, Hartburn, Woodham, and Newbiggen, are all old, and many of them fine, with long chancels of the local character, and Mr. Wilson's illustrations and descriptions of them will repay examination.

As a work of local history and reference, this volume will have considerable value; but for general interest it would have been improved by considerable curtailment and discrimination as to the choice of material.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT the ordinary general meeting on Monday evening last, Mr. T. H. Wyatt, President, in the chair, the minutes of the previous meeting having been read and confirmed, Mr. G. H. West, M.A., F.G.S., was elected an Associate.

THE ROYAL GOLD MEDAL.

The President announced that, subject to her Majesty's pleasure, the Council proposed this year to award the Royal Gold Medal to Mr. James Fergusson (cheers), whose numerous works on architecture fully entitled him to such a distinction, and which were so well known as to need no commendation from him (the President). (Hear, hear.)

THE SOANE MUSEUM.

Professor DONALDSON informed the meeting that Mr. Ouvry and himself had been elected trustees of the Soane Museum and to the Benevolent Fund of Sir John Soane. He (the Professor) had been chosen to succeed the late Mr. Hardwick, while Mr. Ouvry took the place of Mr. Pollock.

THE TOMB OF CHARLEMAGNE.

Professor Donaldson also read a letter from M. de Remistier, a German architect, respecting the paper read by the learned professor a few weeks ago on the tomb of Charlemagne at Aix-la-Chapelle. The writer of the letter concurred with the view taken by the Professor, and corrected one or two slight inaccuracies into which he had fallen.

BUILDING CONTRACTS.

Mr. T. CHATFEILD CLARKE asked what steps the Council had finally determined upon taking relative to the form for building contracts sent round to the members? He suggested whether it would not be desirable that a public discussion of the whole matter should not take place at the Institute. He had carefully perused the proposed form of contract, and it did not seem to him that there was so great a variance between it and the form of contract usually used as to make it a matter of difficulty to bring it into general use.

Mr. J. P. SEDDON (hon. sec.) said the matter was quite open to discussion at an ordinary general meeting, and it was always the idea of the Council that it should be so discussed. All that had been done was to explain the preambles of the matter, and the form sent round did not carry with it any authority, but merely embodied the opinion of the Council that such a form of contract was desirable.

Mr. HENRY CURREY, Fellow, then read an important and interesting paper on

THE NEW ST. THOMAS'S HOSPITAL

(of which building he is the architect). Mr. Currey commenced by a brief narration of the circumstances which rendered necessary the removal of the hospital from its old site at London-bridge. This necessity arose from the construction of the Charing Cross Railway, and although no part of the hospital buildings were required for the purposes of the railway, but only a corner of the hospital garden or ground, still a railway carried across the corner in question (by one of the hideous, trough-like box-girder bridges now so prominent by their disfiguration of some of the finest thoroughfares of London) within 12ft. of one of the wards was considered to be a highly undesirable adjunct to the hospital, and the railway company were compelled to take the whole of the hospital premises. Such being the case, one cannot but regret, said Mr. Currey, that the line was not taken directly across the hospital, passing through the centre of the London-bridge station, thus accommodating both the Brighton and the South Eastern lines, and crossing the High-street at a right angle, instead of the tortuous and inconvenient plan which has been carried into execution at an enormous cost. After referring to the arbitration for the assessment of the compensation (£296,000 being the amount awarded), Mr. Currey, having narrated the circumstances attending the selection of a newsite for the hospital, spoke as follows:—

The question of a new site being settled, I was instructed to prepare the necessary design, and as the subject of competition is one of some interest, I may mention that on my appointment as architect and surveyor to the hospital, now some twenty-five years ago, the governors reserved to themselves the right of submitting any great work which might arise to competition. They did not, however, avail themselves of this right, and although it is not for me to say anything as to the result of the course they took, yet I venture to think that they were relieved from some trouble, anxiety, and expense, and I take this opportunity of thanking them for the confidence they reposed in me. A committee of governors, accompanied by myself, visited several of the continental hospitals, and the committee of the medical staff assisted in maturing the several matters of detail. The design is arranged on the pavilion system, now generally admitted to be the best for hospital purposes, and specially suitable for the land on which the hospital was to be erected. The nature of the site did not admit of the pavilions being placed on both sides of a central court or corridor, as at the great French hospital at Lariboisière, the hospital at Brussels, or the Herbert hospital, but they all ranged on the river side of one continuous corridor, 900ft. in length. This arrangement has the disadvantage of increasing the length of communication from the several departments, but at the same time it renders the ventilation more free by diminishing the length of the courts. The prominent defect of the Lariboisière hospital, viz., the too close proximity of the blocks with reference to their height, has, I hope, been avoided. The pavilions are placed at a distance of 125ft. from each other (the centre court being increased to 200ft.), which distance it was calculated would admit of ample sunlight and air to every block, the axis of the wards being due east and west.

The general disposition of the building will be seen by reference to the plan of the one pair story, on which the isolation of the blocks is more distinctly indicated, the intermediate spaces on the ground story being filled in with lower buildings, for purposes hereafter mentioned, and it was my endeavour to make the plan as simple as possible in its arrangements, for facility of inspection and working. Corridors run the whole length of the hospital on the ground and one pair stories, and connect the several blocks of wards or pavilions. These corridors are lighted by large windows on both sides, and in the event of it being deemed necessary to isolate any particular block, it could be done by putting screens across the corridors, and removing the sashes from the adjacent windows. These corridors are not carried higher than the one pair story, but the flat roof over forms a means of communication to the several blocks on the two pair story. The pavilions are placed at right angles to the corridor, from which a passage leads direct to the wards, on one side of which is the staircase. The wards are designed to be 28ft. in width by 120ft. in length, and 15ft. high, and will accommodate 28 beds, giving a cubic capacity for each patient of 1800ft. The beds are placed at distances of 8ft. from centre to centre, and the windows are arranged alternately with the beds, at a level to enable the patients to see out. A cheerful aspect is given to the wards by the end lights communicating with the external balconies towards the river, where patients may be placed on couches or chairs in fine weather. Small wards for two beds, immediately contiguous to but not communicating with the general wards, are provided in each block for the reception of special cases, which it may be deemed desirable to separate from the other patients. Adjoining the passage are placed the sisters' room, the ward kitchen, and a room for the medical officers' consultation. The staircases are wide and easy of ascent, the treads being 12½in. and the rise 5¾in. The well holes are occupied by the large lifts and ventilating shafts hereafter referred to. The water closets, lavatories, and bath rooms attached to each ward are projected from the main building, and are cut off from the ward by intercepting lobbies, with windows on both sides. The water closets, lavatories, &c., have also windows on all four sides, to provide a thorough ventilation. In this department the foul linen and dust shoots are arranged, communicating with a receiving room in the basement for external removal. Dormitories are provided for the nurses and servants in the attic story, each having a separate sleeping compartment, care being taken to prevent the ascent of any ward atmosphere reaching thereto.

The main hospital may be said to commence on the first floor, and consists of three tiers of wards, there being four smaller wards provided on the ground floor for the reception of accidents, &c. The total amount of accommodation provided is about six hundred beds. The wards have flat ceilings throughout, and the windows are carried up to the ceiling, to ensure a thorough change of air in the upper part of the rooms. From the corridors on ground floor, patients will be quietly and conveniently conveyed by lifts to the various wards (these lifts will be referred to presently); the corridors will also afford a place of exercise for the patients in wet weather, and the covered colonnades adjoining the river will form an agreeable lounge for patients approaching convalescence.

The above description applies generally to all the pavilions, except the southernmost, which is designed for special diseases inadmissible to the general wards. The wards in this pavilion are smaller, and are arranged for males and females, being separated by a central staircase. The wards on the ground story correspond in general arrangement, but in consequence of the main corridor on ground story being placed next the internal courts, the wards are shortened to admit of the introduction of the necessary rooms in connection therewith.

The general entrance to the hospital is placed in the centre, and will be approached from the Palace New-road. The entrance hall is capacious, forming the sub-structure of the chapel, and its dimensions being large it will be found convenient for the reception of the patients' friends at the times appointed for visiting. The steward's or superintendent's offices are placed immediately in front of the entrance hall, so that everything passing in and out of the hospital will be under his immediate supervision. From each side of the entrance hall branch off main corridors of communication connecting all the different departments. The ground floor of the first pavilion to the left is appropriated to the kitchen department, as being as nearly central as possible. It comprises kitchen, scullery, and cooks' rooms, with larder, bread room, &c., on the basement immediately under. A serving place is provided, where the patients' food will be distributed; it will then pass along the corridor to the different pavilions, and be conveyed up a small lift to the different wards. The ground floor of the first pavilion to the right is appropriated to the matron's department, with a commodious room for linen stores. On the right of the entrance hall is placed the principal staircase, which leads direct to the corridor on the one pair story, and will be used by visitors to patients, or for the general purposes of the hospital. It communicates directly with the resident medical officer's apartments, which are placed in the central block, consisting of sixteen rooms and a common room. Two operating theatres are provided (communicating with the corridors) lighted from the northern slope of the roof, and of ample dimensions to admit of a large attendance of pupils. A private room is attached to each theatre for the operator, with a second room in which a patient may be temporarily placed after an operation. Conveyance to the mortuary will be provided from the basement by an underground passage without exciting the patients or the public observation. The dispensary and surgery are placed conveniently for the service of the hospital into the main corridor, and of the out-patients (who are more particularly referred to hereafter), from the opposite side. The laboratory, drug and store rooms are placed in the basement story immediately under the dispensary.

All applicants for relief at the hospital will enter at the covered porch in Palace New-road, and will be received in one of the admission rooms according to sex; they are then informed whether they are to be admitted into the hospital or to be

treated as "casualty patients," or as out-patients. If admitted, they would be passed through the hospital corridor to the wards. If "casualty," they would pass to the respective waiting-rooms for males or females, from thence into the male or female surgery. They will procure their appliances at a window immediately contiguous, and pass out at once. If the applicant is to be treated as an out-patient, he is directed to the out-patient department, which is placed in the corresponding wing. The out-patients enter at a door towards the southern end of the hospital, and pass through a large waiting-room, 110 by 37, in which they will be arranged and classified. The physicians' and surgeons' rooms are ranged parallel with this room. Having been seen by the physician or surgeon, the patients pass into a second room, where they will wait for medicine or appliances from the dispensary and surgery windows, and after receiving them, pass out into the Palace New-road, without entering the hospital corridor. A staircase leads direct from the out-patients' waiting-room to the out-patients' baths, which are provided in the basement. Sufferers from accidents arriving would be conveyed directly into the accident receiving room, and from thence, when the case was serious, immediately through the hospital corridor to the wards, and cases of accident on or in the neighbourhood of of the river may be brought to the hospital and received from the landing stairs.

The administrative offices are placed next Westminster Bridge, and will be approached therefrom; they will comprise the governor's hall, committee rooms, almoner's room, counting house, receiver's room, strong room, waiting rooms, and offices for the clerk and surveyor of the hospital, the treasurer's residence, &c. A staircase will connect the treasurer's house with the main corridor of the hospital. The two lower stories of this block will contain residences for porters. Four houses are provided for resident officers, containing eight rooms each, exclusive of domestic offices. They will be approached from the Palace New-road, and communicate in the rear with main corridors of the hospital. For the last eight years, nurses selected by Miss Nightingale have been trained (the governors believe with great advantage to the public) in St. Thomas's Hospital; and in the design for the new hospital, provision has been made for an increased number. The training institution adjoins the matron's residence, and will afford accommodation for forty probationers, who will be trained to the hospital wards for the council of the Nightingale Fund. Each probationer is provided with a separate sleeping apartment, ranged round a central gallery, with all necessary bath-rooms, &c, and a large day and dining room on the ground floor.

The chapel is placed in the centre of the building, communicating with the corridor, with convenient access for both sexes. The school buildings occupy the southern end of the site. They consist of a large museum, 85 by 30 and 34ft. high, with two galleries, a museum for chemistry and materia medica, medical, anatomical, and chemical lecture theatres, library and microscope room, dissecting and post-mortem rooms, chemical and pathological laboratories, &c., affording the medical student opportunities rarely if ever equalled in completeness. The extreme point is occupied by gardeners' sheds, stables, &c.

The building stands partly on land reclaimed from the river and partly on the shore. The foundations on the river portion are carried down to the London clay. Those on the shore stand on a sound bed of gravel, which overlays the London clay, the difference in level being obtained by wide steppings, (shown on the sections.) The ends of the blocks next the river have a solid foundation of about 22ft. deep over the entire surface, forming a toe to the whole. The long flank walls of the pavilions have a foundation 10ft. in width, and the same depth, 22ft., up to the old river wall. The concrete is then stepped up, and a platform of concrete, about 5ft. deep, is laid over the whole surface of the remaining portion of the building. The land or spring water stands at a level of about 4ft. above the clay. A drain was laid along the whole length of the hospital at the back of the river wall to a sump, and the excavations were all pumped dry before the concrete was put in. The whole of the concrete is composed of blue lias lime and clean Thames ballast up to a little above the land water line in proportion of six to one, all above that in the proportion of eight to one. The strata on the shore consisted of made ground, then gravel varying in compactness, resting on the London clay, which rises gradually up from the river. The strata on the river portion consisted of loose and sandy gravel down to the clay. The Embankment wall is also carried well down to the clay. As regards the terrace wall which intervenes between the end of the hospital blocks and the Embankment walls there was no weight of superstructure to carry, but it was necessary to go down to the clay to get anything like a bottom. To have carried the whole down would have been very costly. It was therefore determined to build it on piers and arches. These piers were carried down 5ft. square in concrete, six to one as before, and arches turned from pier to pier in Portland cement concrete, in the proportion of five to one, the ballast being fine and small. The arches were turned on boxed centres, which were shifted from time to time as the concrete hardened and the ground filled in all round. Two or three of these arches were turned in Coignet's béton as an experiment, but the Portland cement concrete was found equally strong and cheaper. The foundation of certain portions of the low outbuildings at the extreme end of the ground are executed on the same principle on piers and concrete arches; I am glad to state that owing to the care with which the foundations generally were put in and the superstructure raised, I am unable to discover the slightest settlement over the whole area of the extensive building. Scarcely any relics of antiquity were found in the excavations.

During the execution of the foundations the working drawings and specification for the superstructure were completed, and the bills of quantities were prepared by Messrs. Strudwick and Co. and Mr. Richard Roberts, and tenders were received on July the 18th, 1867, from fourteen of the most eminent builders, the amounts ranging from £382,000 to £332,748, which latter was submitted by Messrs. John Perry and Co., of Stratford, and which, after full consideration, was accepted. Had stone ashlaring been used instead of red bricks the additional cost would have been about £25,000, which the governors did not feel justified in incurring, and which, personally, I see no reason to regret.

I will now proceed to state a few details of the construction of the warming and ventilating arrangements, and the cost. The footings were built with what are technically known as No. 2 wire cut Galt bricks, and the specification provided that the walls generally were to be built with the very best stocks, but that the piers of the flank walls of wards were to be built with Galt bricks, for reasons which I will presently describe, but owing to the great difficulty in obtaining a satisfactory stock brick in such quantities as we required the contractor found it to his advantage, considering the small amount of fracture and waste, to use Galt bricks, and the whole of the work is executed in that material. They make excellent good sound work, but unless the joints are left very rough on the edge they do not afford so good a key for plastering as ordinary stocks. The greater portion were supplied by the Burham Brick Company. Inverted arches are turned under all window openings above the footings, and the piers in flank walls of wards being reduced to a small area by the large window space desired, and having to bear on the ground story an accumulated weight of 110 tons, were carried up with the very best Galt bricks in Portland cement, with Portland stone bonders the whole size of piers, introduced at every 4ft. in height. Every alternate window in basement was omitted with a view to obtain a larger area of piers on that story. Hoop iron bond is introduced at the level of each floor where it runs continuously round the building without any necessity of severance. The area walls, 14ft. in height, where built as shown on plans and sections, with a view to resisting the great pressure of earth filled in at back, and to preserve the facing from being disfigured by percolation the base of the pockets was filled in with concrete. The building is faced with red bricks, and great pains were taken in ascertaining the best quality for the purpose, and none appeared equal in quality and colour to the Fareham brick. Negotiations were therefore entered into with Mr. Cawte, of Fareham, in Hampshire, who opened a new field adjoining his old works, and made special arrangements for supplying the quantity required, which were put into vessels at his yard, and brought alongside at Westminster, thus avoiding the damage and breakage of railway transit and carting from station. The bricks were made specially, and the size so arranged as to bond accurately with the Galt backing. The bricks are excellent both in colour and quality, and Mr. Cawte used every exertion to keep us supplied with material as the work progressed. The number of bricks consumed, exclusive of the facing bricks, has been about twenty-five millions. The stone used is for the most part brown Portland, from Messrs. Hollands' Waycroft and Maggott quarries; 17 saw frames, besides hand saws, have been constantly at work sawing the material, and the capacity of these saws appear to have been the gauge of the progress of the structure. Steam moulding machinery and large rubbing beds have also been used to a considerable extent. The quantity of stone used has been about three hundred and seventy thousand cubic feet. The consoles under main cornice, the caps of columns, and pilasters, the balusters, and the vases and terminals on balustrading are executed in Ransome's concreto stone. The material appeared peculiarly fitted in the present case, where there was necessarily a great repetition of the same model, and consequently a considerable economy. Had it not been for this useful material I should probably have had to be content with the long line of balustrading, unbroken by any vase or terminal. The pedestals would have remained vacant as they do in many instances where designed for sculpture, but the sculpture never arrives. It harmonises well with the Portland stone, and although many of my professional brethren would hesitate to use any artificial material, I venture to think that such hesitation may be carried a little to excess. The floors and flat roofs are constructed with wrought iron girders and "Dennett" arching. The latter material, as you are well aware, is composed of broken bricks or stone and sulphate of lime, in the proportion of three of brick to one of sulphate of lime, spread as concrete on a centre; a large quantity of the slag from the potteries at Lambeth has been used, and forms an excellent material for the purpose. The spans are for the most part 8ft. or 9ft., the thickness at the crown being 4in., increased to about 9in. at the haunches.

(To be continued.)

ON ARCHITECTURAL DETAILS APPLIED TO OTHER USES.*

(Concluded from page 52.)

AFTER passing in review the rise and decline of architecture in Egypt, Assyria, Greece, Rome, and Mediæval Europe, and the influences under which those effects were brought about, Mr. Pollen gave a sketch of the Classic Renaissance in Italy, and then proceeded to detail the various elements of architectural constructions and their varied uses. Having done this, he came to the real subject-matter of his paper, viz., the application of architectural details to other uses than in the construction of buildings, viz., to furniture, &c. On this subject he spoke as follows:—Look through our museums and collections, to which have been brought the splendid remains of the furniture and other objects in daily use in the sixteenth and seventeenth centuries. Many of the best specimens of these objects are made as if models for architecture. Columns, brackets, lines of a ovolo mouldings, cornices, coronæ, fasciæ, bases, plinths, dados, and other such members belong strictly to architecture. The proportions and the requirements of architecture demand these subdivisions; but the proportions and the requirements of furniture, or, again, of those objects which form a sort of link between furniture and architecture, do not demand this element. Small objects are easily and sensibly constructed of pieces of wood or bands of metal without divisions, and when so made are easily decorated with designs or dispositions suited to their forms. They do not want elaborate composition. That which looks well in architecture does not, of course, look ill in a model; but the reduced image or model, or the imitation, looks well only because it is a record and acts as a reference to principles sound and good elsewhere. If we turn over books containing the works of Lepantre, Delorme, or the later productions of Marot or of the Dutch and Flemish designers, all seem to have been absorbed by their notions of building. In Holland and in this country this principle of design ran to grotesque extremes. If we refer to examples of Dutch, even of Flemish, furniture, in the shape of cabinets, chests, chairs, &c., or to our own seventeenth century furniture,

* By J. HUNGERFORD POLLEN, Esq., M.A., of the South Kensington Museum. Read before the Associated Arts Institute, Saturday, January 7, 1871.

it must be admitted that the bedstead and cabinet fronts divided into heavy and grotesque arches, and abounding in lions' heads and lions' feet, are curious and interesting, but scarcely worthy of modern imitation. The lions' heads represent the spouts of Greek gutters, and the arches of cabinets are designed, perhaps, from recollections of the triumphal arches of Rome. But in these structures columns did real work, and arches were the only possible way of covering the space between the piers. In furniture, looking-glasses, wall panels, and other such uses, these features are actually useless and in the way. Any one of my hearers must have seen columns of this kind which are mere weights added to doors, and come out when the door opens as an adjunct applied to the stiles. The arches of bed-heads and the same forms in cabinets are merely recessed panels, which have to be provided for at the cost of the accommodation required. Furniture made to contain should certainly have all the interior capacity which the outlines of the whole piece will allow. I know that though this practice of designing only or chiefly as if we were always designing for some architectural feature is not wholly the growth of modern academies, and I wish to refer to one or two notable instances to be met with in older schools. The Classic sarcophagus, stone coffin, or funeral monument is certainly generally in the form of an architectural façade or construction. We may refer to the beautiful Lycian tombs in the British Museum, and to instances innumerable of the old sarcophagus. But it should be borne in mind that these forms, though not required, were symbols of a real idea. The tomb was *domus ultima*—the last home of man. It was small often, for the bodies were burnt. But the idea of this abode was that it was his *home*, his last house. Hence it was roofed—a gable, acroteria or corner tiles representing the rows that covered a roof formed elements necessary to remind the survivors that this was the last house or home. The Egyptian tomb was an actual house, with rooms, halls, and so on. The Mediæval tomb was suggestive of hopes and expectations rather than of final shutting-up in the chest or in the urn, and the form and disposition of the images or mementos of the dead was conceived accordingly. In the Mediæval architecture and the decorative sculpture and painting of that period the representations of man had usually architectural details attached or accompanying, such as the niches and tabernacle work borrowed from architecture, and used in glass painting, and often in recumbent figures on tombs. But here again the general objects of sculptured representation were heroes and saints, and the church or sacred building was significative of more than a mere room. It was supposed to be symbolic of the union of Christians into a definite body. The word "church" had then two significations, and the spiritual structure was said to be built up of living men. Hence the natural requirements for the protection of the image of a saint or a hero by placing it in a niche, and both to protect and give it every positive tribute of honour, covering it over with a rich architectural pinnacle or roof was the expression of a definite idea, as the house-shaped tomb was of a real house. But pieces of furniture deliberately designed on architectural forms I never could think successful. The Coronation Chair in Westminster Abbey was, perhaps, designed as a half religious and sacred shrine. It contains the famous "Stone of Destiny" taken by Edward I. from the Abbey of Scone. To sit and be crowned on this seat had a certain significance. To surround it with all the pomp and religious connection possible was very likely an object of the English kings. But a chair of wood has other more convenient and more natural methods of composition. When we compare with that sort of chair those of Evesham and other known specimens, the form strikes one as out of place in woodwork. A still greater anomaly is the silver chair preserved at Barcelona (of which a plate can be seen in Mr. Henry Shaw's "Mediæval Dresses." There the legs or supports of the chair are thin mullions of Gothic windows, and cusped tracery fills up their upper portions, and buttresses and arches compose the back. One might follow this sort of design into the tables and chairs we sometimes meet with in the later Renaissance period, and in the modern revival of furniture for Mediæval rooms and houses. Pugin himself pleaded guilty to many early extravagances of this kind when he was designing the furniture and fittings of Windsor Castle. On the consideration of shams, and architectural shams, I do not touch; in designing buildings suggestions are often made of details or structure which might be used even though they did not exist. Pilasters, for instance, are not columns or piers sunk into the wall. But as such a structural resource would be not otherwise than legitimate, it is sometimes suggested in the place and situation in which it would be no violation of propriety. My objection lies against the applicability of the forms themselves where they are used. The form of an interrupted pediment, again, is a favourite element of ornamentation of the seventeenth and eighteenth centuries introduced in the frames of mirrors, in cabinets, and in panel work of all kinds. A bust usually parts the two sloping members. But what possible meaning has an interrupted pediment? It does not represent a gable in architecture, nor does it help to protect a gable-shaped recess or niche of sculpture. Such a form could protect nothing. The bust itself, mounted on the base of a column, is to my thinking an awkward, a somewhat undignified, arrangement. The block of a terminal figure, or the old arrangement of bringing the head through a circular opening, is the best method of composition for a head in round relief. The heavy cornices with which these pediments are finished seem to me altogether out of place on any small scale. Whether in woodwork, plaster work, gold, ivory, or on any unreal scale of of this kind, it seems to my notions a misuse of form. With regard to figure sculpture and its representation in any material, it seems to carry with it what is congener to human representation. If we paint or sculpture a man we add to it whatever would be a man's natural requirements. Musical attributes, arms, and so on, also niches and other architectural details, are naturally represented as the implements or as the requirements of man, or of the man, whoever it be, who is represented. But then these are records or representations, parts of a picture, not essential methods of construction.

I make these remarks on some of the difficulties that beset artists when they are not actually riding the tall horse of architecture. There seems to me a certain loss of architectural design when its members and features are considered so many mere arbitrary ornaments, without any necessary meaning or significance, and without any restriction to their general use. It seems to me also that the vulgarity that has lowered our commonplace architecture, that for which accomplished architects are not employed, is owing in some measure to this ignoring of the definite meaning of columns, brackets, arches, the composition of bases, sub-bases, and so on, in architecture.

If we look at old Greek ornamentation, we do not see their chairs, tables, sofas, cups, bases, and mirrors containing the choicest specimens of Greek design. But these designs are appropriate to the objects they adorn. Of living races we shall find none equal in this inexhaustible invention and resource to the Japanese. But I do not mean to slight the decorative work of the modern Italian schools. In the first years of their existence sculpture and figure design formed the leading object of their compositions. It was but gradually that architectural ornamentation overrode this purer design. Yet they have left us great and effective designs, and their ornamentation on architectural fronts, walls, and panels is their strong point. Much that is, when taken in detail, rude and unworthy, is put together with much mastery of general design—a sense of the impressiveness of a great whole, in other words, with effect. Our Elizabethan architecture and ornament is full of anomalies. It scarcely bears restoration or imitation. But we all value it as we see it; so also are we admirers of the old furniture and decoration which has such faults. We are so because it has certain great qualities, or because of the excellence of the workmanship, or from its having picturesque or impressive elements in it, though it would not do for reproduction.

While any school of designers is possessed by great ideas and thoughts which are derived from familiarity with really great works, and the impression which intimate study of those works has made, such a school will always be influential; it will always leave a mark. It is that mark which excites the admiration or appeals to the sympathy of future generations. Now, however, we are a race of revivers. We are not possessed by very dominant ideas. We revive on the authority of others rather than under strong impressions made upon ourselves. It is natural we should look to systems that have been reduced to rules and applied to a thousand uses under pressure of various kinds, modified by local prepossessions and habits of thought. The easy resource of taking ready-made elements of composition blinds us somewhat to the principles on which selections and adaptations from other systems ought to be made. To adapt from sculpture and painting, and still more from architecture, to woodwork or decoration, may be sometimes allowable for certain purposes, within certain limits; but it is an adaptation. Wooden objects, or objects in metal, or any other fine work, have each certain capabilities of decoration quite distinct, possible in each material, suggested by size, use, nearness to the eye, and by the value of the object. Designers should invent or design in accordance with these conditions, rather than put up with forms and details which chance to come readily to hand, but which belong altogether to other walks of art.

THE FISH-POND ROOFS OF LONDON.

DURING the present winter we have seen, not London only, but the entire country, more than once covered with a mantle of snow. We have what people call "an old-fashioned winter," with an influence impartially extended to every county in England. Has it ever struck the Londoner that his own condition during the supervening thaws is quite exceptional, and wholly unlike that of his provincial fellow-countrymen? In the provinces he may see the snow lying for days and weeks on the sloping roofs, to melt when the thaw comes, fall spontaneously into the eaves-gutters, and find its way safely and without hand labour to the ground. How different is the state of things in the metropolis! Here we cannot afford to wait in patience for the thaw. We have sloping roofs indeed, but roofs innumerable whose inclination serves not to convey the fallen snow from off our dwellings, but to deliver it into their very midst, where it lies in thick heaps in the "V-gutters" above our ceilings, to find its way suddenly and without ceremony or warning of any kind into our bedrooms. We learn, after one or two "floodings," how to deal with the enemy in our own metropolitan way. Country cousins who may happen to be in town after a snow-storm may observe our "tricks and ways," and marvel at them. Do we leave the snow on our roofs, as do our country cousins? By no means. Well knowing by sad experience that London houses are not built to be snowed upon, we hire men to get through the man-holes of our roofs, and without even the Edinburgh "Gardy-loo" of Mistress Winefride Jenkins, pitch it off the middle of our roofs into the middle of our streets. Down falls each spadefull with a dull thud below, not always with a very correct aim, for most of our fish-pond roofs are masked with a compo balustrade or high parapet, over which, with an upward initiative, it must perforce be pitched. How is a man to know how, where, on what or on whom it may fall? perhaps harmlessly (as he hopes) into the middle or side of the carriage way, whence it must be removed by the scavengers; perhaps (worse luck) upon the roof of a passing cab; or, by mal-adventure, upon the footpath, with or without an intercepting wayfarer, as the case may be. Up it goes over the parapet; and, as

> Whatever goes up is sure to come down,
> Let every one take care of his crown.

All this is ludicrous enough, but will any one say it is in the least an exaggerated picture of life in London after a snow storm? It is unlike anything elsewhere in England. These wretched V or fish-pond roofs are to be seen nowhere but in London. A stranger passing quickly, say by railway, along the rear of a row of London houses will be puzzled to say where is the middle of each dwelling. Reasoning by provincial experience he will naturally think it coincident with the highest point of what he thinks are the span roofs. A closer inspection reveals the fact that it is the lowest part of the roofs (the valleys) that really stands over the centre of each dwelling, and that the apices he sees are really the tops, not of the roofs, but of the party walls. He is thus introduced to the profiles of the fish-pond roofs of London:—

> The "V" or "fish-pond" roofs whose weight
> Of plaster, and lead, and timber, and slate,
> Rests on the quarter-partitions, that lie
> Piled up several stories high,
> On timber joists that hardly can
> Bear their own weight; for they've to span
> The depth of the house that Jack built.

It is many years since in somewhat similar words to the above we denounced these roofs in the BUILDING NEWS. They are, if we mistake not, fiercely condemned by the late Mr. Alfred

Bartholomew. Yet they may be still seen in course of construction all round the metropolitan suburbs—at Notting Hill, Holloway, Kentish Town, &c., and many have been the flooded ceilings they have caused during the thaws that have succeeded the late snow-storms. We quoted the other day some remarks in the *Daily Telegraph* on the miserable condition of London after a snow-storm, especially in the choked up state of the streets, and the duty of the Metropolitan Board of Works to clear them of the fallen snow. But very much of the snow that encumbers our thoroughfares—snow that no single day's thaw will relieve us of—consists of the heaps formed by these discharges from our roofs, constructed so as to stow it away (as a veritable rain-water supply) behind our parapets. If the Metropolitan Board were to institute a law forbidding the throwing snow off the roofs into the public thoroughfares, it would do much to remove, or at least to abate, this dreadful evil, and in time we Londoners might substitute for our favourite fish or snow-pond roofs the ordinary span roofs of our country towns, and indeed of mediæval London itself; for these hideous contrivances are comparatively quite modern, hardly known before the bad old times of George IV. They seem to have come in with Hessian boots, sandals, swallow-tail coats, and hobby-horses, and the sooner we get rid of them the better for our streets and for our ceilings. Who knows but that a clause in the Metropolis Local Management Act or a by-law of the Metropolitan Board might in time inaugurate a new style of London street architecture—a high-pitch style of roof, that should render it no longer necessary to pitch the snow off the tops of our dwellings into the streets? We don't want the snow transferred to the streets, and we do really need an entirely new style of street architecture. S. S.

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page* 28.)

PLATE 19. — CONSTRUCTION OF WREATH FOR QUARTER-CIRCLE STAIRS.

LET quarter circle for centre line of rail be struck with a radius equal to a square step. Draw tangents to form right angle A, B, C. Set off half a step on each side of B, and draw face of risers.

Next, set off one or two square steps. This arrangement of plan throws both shanks of wreath on same pitch as that of the stairs, and diagonal A C directs construction of mould as shown on lower part of plate.

Let A, B, C equal the two sides of square; same as on plan.

Extend A B, and make B 3 equal a riser. Join 3 C. Also, C A extended. Thus giving ordinate. Have seat square with it. Draw B L parallel with ordinate.

Let A T equal B 3 on right. Join L T extended. This is the pitch or major axis. To find elliptic curves, let A D equal A B. Set off on each side of D half width of rail. Then square up to cut the pitch.

Let T S equal T L. The drawing is now ready for mould. Join the edge of a board, and run a gauge line. Lay board on and mark L, T, S. Square over the lines. Let L E and S K equal L B. Make T R equal to A C. Join R K and R E both extended. These lines are tangents on mould, and when in position stand on pitch of stairs, and to be correct R K must equal 3 C on right. The straight wood on shanks may be any length desired. The width of mould is determined with greater nicety by finding the bevel for joints. In this manner: Take B for centre, and for radius a circle touching 3 C, cutting to left of 3. Join intersection and C, which gives required bevel. Next, set off half width of rail below B 3, cutting bevel indicated by dotted line. Set the compass along bevel. Take any point on tangents E, R, K, and make arcs, as shown. Draw straight wood cutting T E and T K. Next, let T V equal A B. Set off on each side of V half width of rail. Now find points to insert pins and sweep mould with a string. The mould represents upper surface of wreath, the stuff cut square through. The application of bevel to joints gives a direction to draw dotted lines shown on surface. Then cut off slab H on the left, and work to bevel. This done, apply a square to the bevelled edge, and draw from centre of joint the dotted line cutting at H. Continue this along edge, and square with joint.

Now transfer 2 K to that on edge, and mark the plumb line with pitch board, in a similar manner to that shown on left. Next, lay mould on. Keep straight shank on convex side fair with that of beveled edge, and let straight part of mould on concave side, to the right, be fair with dotted line. Mark the stuff. Apply in like manner to under side.

Here the ground plan is arranged to have straight shanks of wreath stand on same pitch as that of the stairs.

How do we know that this drawing will produce such a result? Because, by observing the position of riser on left, it will be seen that its face stands half a step from corner B, and B 2 on right also equals half a step. Therefore, the centre of wreath must be a straight line; as can be proved by unfolding tangents A, B, C, on a board, in similar manner to that shown above the mould, it having corresponding letters.

Let B 3 equal a riser. Join A 3 extended. This having cut perpendicular from C at D, gives height of two risers, which correspond with that of A C on plan.

Let us go a little farther, and show pitches on concave and convex sides of wreath. Have rail, say 3½in. wide. Let A 2 and A K each equal half its width. Join 2.3 extended.

This gives 2.3.2 for pitch on concave side of wreath, and is much greater than that of A 3 D, which runs through centre of plank and agrees with tangents on mould. Join K 3 P. This being the pitch on convex side, it falls, and makes a different inclination. Now, suppose we increase width of rail, say 5in. This would cause pitch on concave to be still greater, and give wreath a clumsy and crippled appearance.

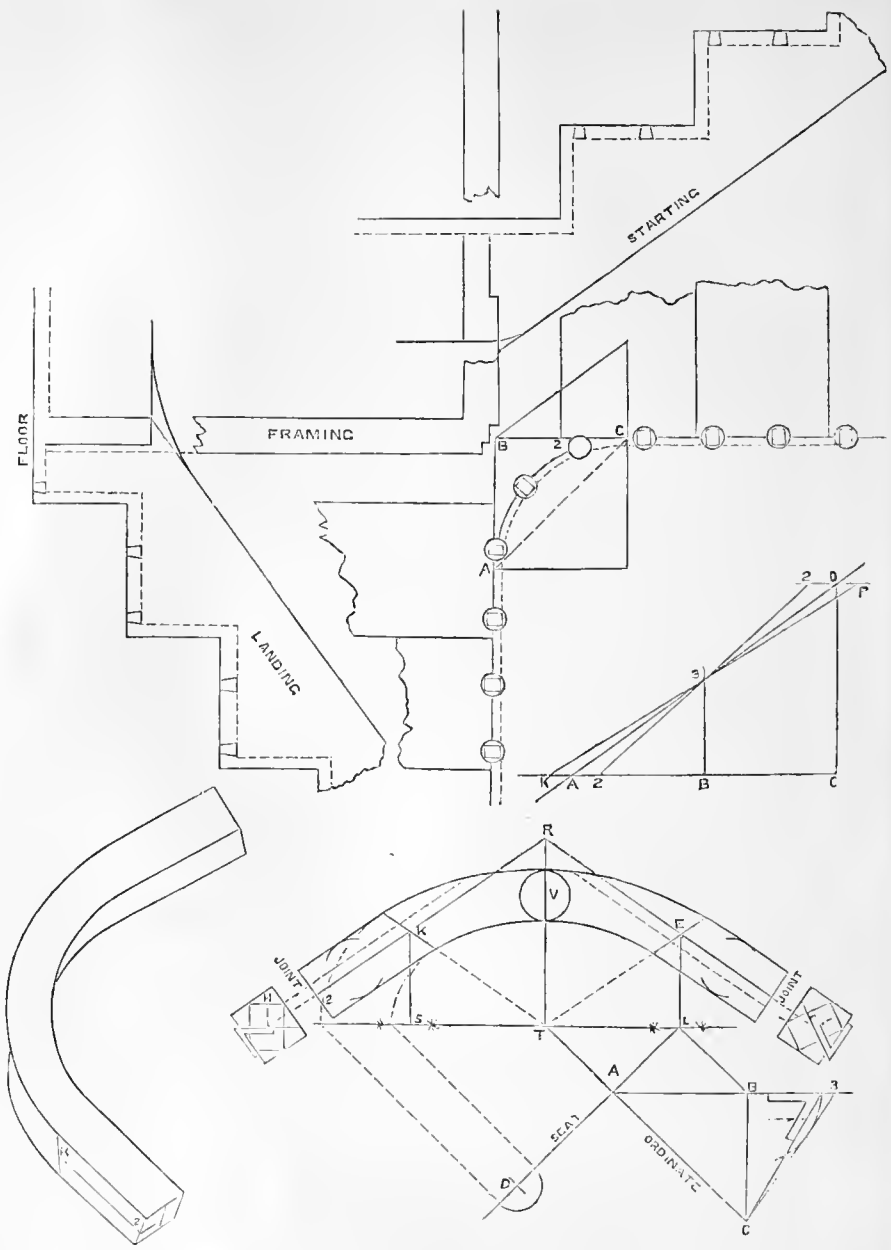
Next plate will show how to obviate this defect when large rails are required. The present drawing, however, is proper for rails the width of which do not exceed 3½in.

The outside strings of these stairs may be plank, which answers for carriage.

Let the corner for framing be cut, as shown, to receive carriage landing and starting. The cylinder may be staves and let into strings.

Make all the cuts according to plan.

Have framing and everything ready before you begin to fix.



NEW ELEMENTS OF HAND-RAILING.—PLATE XIX.

* This series of articles is a reproduction of ROBERT RIDDELL'S work on the subject, published in Philadelphia, and by Trubner and Co., London.

MONUMENTS OF ART.

ON January the 6th we announced the publication of a unique and comprehensive series of engravings illustrating the history of art from the earliest ages. The unusually dull weather we have had since then, and particularly in London, interfered with our plan for a short time. We now give the first plate, which consists of illustrations of groups of Assyrian sculpture, and a description from the pen of Dr. Zerffi, Professor of the History of Art at South Kensington. As we proceed our subscribers will perceive what a valuable work in art, the richest of the kind ever published in Germany, they will by-and-by possess.

DECORATIVE PROCESSES.

By "An Experienced Workman."

(*Continued from page 52.*)

THE ground for graining oak should always be thoroughly hard before commencing graining; if it is not so it is apt to reeve or curl in the act of figuring or marking-in the lights, and when the work is varnished these marks show a dirty edge, which is very objectionable in the finished work.

In the mixing of oil graining colour there are two or three things necessary to be noticed in order to its answering the purpose intended. In the first place the colour should work clean (technically "rub-in clean") and free. It will often happen that the colour will work stiff, and consequently dirty, and in this state will not only produce dirty work, but will occupy thrice the time in rubbing-in compared with colour properly mixed. Oil graining colour also requires to be megilped—that is to say, that oil colour alone will not stand when it is combed; the marks made with the comb will all run one into the other, and will thus be obliterated. To prevent this running the colour requires to be megilped, so that the comb marks will retain the exact form as left by the comb. This desirable end is accomplished by various means, amongst which may be named the ordinary bees'-wax of commerce, soft-soap, hard-soap, lime-water, whiting, and pure water. When bees'-wax is used the best means of dissolving it is to cut the wax into thin shavings or shreds; these are put into a suitable pot or can (earthenware or tin will do), half filled with pure linseed oil, into which a red-hot poker or other piece of iron is plunged, and stirred well. This will dissolve the wax thoroughly and mix it with the oil. When the wax is all dissolved the vessel should be filled with either oil or turpentine, which still further dilutes and mixes the wax, and serves also to prevent it from congealing, so that it may mix with the graining colour thoroughly. This should be properly seen to, or else the wax is apt to remain in lumps in the colour, and when the colour is spread upon the work for graining the wax will be spread unequally and will not harden, and, in fact, will not dry in parts, to the manifest injury of the work, so that it is absolutely necessary that the wax should be thoroughly mixed with the graining colour in order to produce good work. If soft soap is used, it should first be thoroughly worked up on a pallet or a board with either whiting or patent driers; by this means we break up the soap and amalgamate it with the driers, and it will then mix properly with the graining colour. Another method is to break up the soft soap in water to a thick froth or lather; with water in this state it may be beaten up and thoroughly mixed with the oil colour. When lime-water is used, about 2lb. of slaked lime should be thoroughly mixed in a paint-can full of water, and the lime allowed to settle; a portion of the water may then be added to the graining colour, and the two well stirred together until they are thoroughly amalgamated. If whiting be used for the purpose, the whiting should be ground in oil and then mixed with the graining colour. Pure water will also answer the purpose. As a matter of course, some grainers like one and some another of the above-named megilps. The wax is the most effectual for the purpose, but there are grave objections to its indiscriminate use. One of these is the fact that the wax causes the grain to stand up too high above the surface of the work, and as the natural grain of oak sinks below the surface in the real wood, it follows that the less the grain is raised in the imitation the nearer it will be to the real. This raised grain is also objectionable because it destroys that flatness and equality of surface so evident in the real wood. Soap, which in working has a medium degree of elevation of grain, is very objectionable in use, inasmuch as it is liable to cause the work to crack after it has been some time varnished and become hard, and it is doubly objectionable for use on outside work, as the frequent variations of temperature soon affect all grained work in which soap has been used, and is a fruitful source of cracking and blistering. Lime-water has also a tendency to cause varnish to crack. On the other hand, whiting, when used in oil graining colour, although it has the same effect as wax in causing the grain to stand up too high, also makes it work spongy and impoverishes the colour, for the moment whiting is mixed with any semi-transparent colours—such as Vandyke brown, burnt sienna, &c., &c., their purity and richness is destroyed. On the whole, we prefer to use pure water, for if it is well mixed with the oil colour, it answers the purpose of megilping it sufficiently to hold the combing until it sets; the water then evaporates and leaves no injurious effects behind, and the projection of the grain is less than it is if any other medium be used. The most useful colours for mixing oak graining colour are raw and burnt Turkey umber, Oxford ochre, Vandyke brown, and burnt sienna. The first three, with the addition of ivory black, are, in our opinion, all that is required for mixing any shade of graining colour. For light oak or wainscot graining colour, mix two-thirds linseed oil with one-third turpentine; add a little Oxford ochre and raw Turkey umber in sufficient quantity, according to the shade required and amount of stuff mixed. No rule of quantities can be laid down here, inasmuch as the quantities must be regulated by the workman at the time of mixing and place of using. Terabine, or liquid driers, should now be added, the quantities being governed by the fact as to whether the graining colour is required to be quick or slow drying. A safe and efficient quantity to use (that is, if the liquid drier is of the best quality) is about half an ounce to a pint of colour. This will cause the colour to dry in about seven or eight hours, but twice the quantity may be used with safety if the colour is required to dry very quick. Sugar of lead ground in oil may be used as a drier for graining colours, but the liquid drier is better. Many persons use the ordinary patent drier, which, if used in sufficient quantity, will also act as a megilp; but we altogether object to its use, as it not only injures and causes the colour to be muddy, but it is spongy, stands up too high, and, in fact, has all the bad qualities of the other megilps, without a single redeeming quality of its own. We may now briefly sum up the foregoing description of mixing oil graining colour, as follows: Mix burnt umber or Oxford ochre with linseed oil and turpentine in a can or pot, add terabine or liquid driers, beat or stir well up together; add pure rain-water in the proportion of one half pint of water to three pints of oil and turps; beat or stir up until the whole is thoroughly mixed together, then strain the whole through a fine strainer or a double fold of fine muslin. The colour should be thinned until it works freely and lays on clean. What we mean by laying on clean is that when the colour is being brushed over the work to be grained, if it is not properly mixed it will gather or accumulate in the quirks and corners, and will be shady and dirty-looking; but, if properly mixed, it will lay on evenly, and be easily spread, and will look clean and of one uniform shade of colour. It will be evident that this is a very nice point in the mixing, and is of great importance to the success of the work. Care and cleanliness of working is as necessary to the successful carrying out of this work as it is to more important work; and therefore it is essential that the colour, the brushes, and all working tools should be clean to begin with, and be kept clean. In mixing the colour for a medium shade of oak, it will be found best to use raw Turkey umber with a little burnt added, and for a rich dark oak burnt umber may be used alone, except a cool tone is required, when a little ivory or drop black may be added. We now come to the question of combs for imitating the grain of oak (hence the name graining). Combs are made of different substances, and are, of course, of different sizes. There are combs of horn, of steel, gutta-percha, vulcanised india-rubber, cork, and leather. Horn combs were about the earliest used for this purpose; these are made in exactly the same manner as the ordinary tooth-combs, and cut to the various sizes required. But there is this essential difference between the two: that while the teeth of the hair comb is cut taper and with a fine point, the teeth of the graining comb are left square and blunt at the ends, and of the same width throughout their whole length. The teeth are also about double the length of those of hair-combs. There are several sizes made, varying in width from a twentieth of an inch to a quarter of an inch, and some are graduated from fine to coarse, but these are not of much use in working. A Sheffield firm commenced some twenty years ago to make combs of thin steel, a decided improvement upon the horn comb, inasmuch as the teeth are not so liable to break in working, and they have a good spring, and are not clumsy in the handling. They also wear well, and are easily kept clean and in working order. There is one objection to the steel comb, especially the coarser-toothed ones: they do not comb clean, and do not part with the colour freely, and, as a consequence, the grain is left ragged and dirty looking. To remedy this fault, thick shoe-leather, gutta-percha, and vulcanized india-rubber combs are used for the first combing, and the fine steel combs for the second. These soft combs are all cut or prepared in the same manner, namely: they are first cut into squares of various sizes, from one to four inches. The edges must be cut perfectly square and level on all sides. To cut the teeth, it will be found the best plan to place a square either upon the edge of a square table or against a strip of wood and held firmly; the interstices between the teeth are now cut away with a sharp knife to the depth of about a quarter of an inch. By cutting in a slanting direction each way, the space between each tooth will be formed by two cuts, and the teeth may be left fine or coarse as may be desired. These combs cannot be purchased ready cut, and therefore it is necessary that the workman should cut for his own use. It must be understood that in cutting these combs, the interstices are not cut through the whole thickness of the material, but only bits are cut out of the edges; they act much better thus, and when they become worn with work the edges may be again squared and the teeth re-cut, thus forming a new comb. And so we may go on time after time until the whole of the gutta-percha or other material is used up, being a very economical use of material. For good serviceable work we prefer to use gutta-percha in conjunction with the finest cut steel combs, and the cork combs for occasional use on first-class work. The gutta-percha is cheap, wears well, is easily cut into any size, or very fine or coarse, and will do its work well. The cork is superior in many respects for producing really good work, but unfortunately it does not wear well, and therefore is not so serviceable for general use. Suitable cork may be procured at the cork-cutter's, and should be chosen with as few holes or bad places in it as possible, close in the grain and firm in texture; the cork-cutter himself will be the best judge, and he will for a trifling extra charge over and above the price of the cork trim and square it into shape, and cut it up into the sizes required, and ready for cutting into combs, which will, of course, be done in the manner described before. These combs should in the first place be quite as thick as the cork will allow when trimmed and made level, in order that when the teeth get worn the edges may be again squared and the teeth re-

cut, thus economising the cork to the fullest extent. The cork comb when properly cut makes excellent work, clean, sharp, and distinct, and yet leaves a glaze of colour on the lightest parts sufficiently strong to show the figure or markings. The importance of good combing cannot be over-estimated in imitating oak, and we have no hesitation in saying that no oak graining can be considered good work except the grain is well imitated. Many grainers scarcely pay any attention at all to the combing, and seem to think that it is but of secondary importance. They are quite content if the figure is only shown strong enough, and some in fact do not trouble to comb the work at all, but lay in a dark graining colour, and just stipple it or streak it with a duster, and then wipe out the figure, which style of figuring as a rule stands out so strong and positive that it is the first thing one sees in going into a room; and on outside work it can be seen across a wide street. Now we consider this class of work as utterly opposed to good taste, and vulgar in the extreme, and we are inclined to think that it is this staring vulgarity so evident in much of the so-called oak graining that has brought the art into such ill-favour with men of good taste. This need not be so, for it is quite as easy and will occupy just as little time to execute it in such a manner that it will be as quiet and in as good taste as if it were the real wood, which is never out of place or out of harmony with its surroundings. On this point, however, we shall have something further to say in a future article.

(To be continued.)

BUILDING NEWS SKETCH BOOK.

ST. MACHAR CATHEDRAL.

THIS cathedral, now used as the parish church of Old Aberdeen, is a very good example of the severe style of architecture necessitated by the obdurate nature of the building stone found in the district. It has a peculiar interest as being the only cathedral built of granite in the United Kingdom. Unfortunately, the nave, two western towers and south porch, are all that remain of the original structure; these were erected at the cost, and during the episcopate, of Bishop Leighton, 1422—1440. The short spike-looking spires, which are of freestone, were added by Bishop Gavin Dunbar about 1520. He also decorated the interior of the nave with a fine flat panelled ceiling of carved oak, containing 48 heraldic shields of Kings, earls, and bishops of the period. The decayed parts of this ceiling, and the inscribed frieze, have recently been restored and re-illuminated in their original style. The large seven-light window in western front has just been filled with a stained glass memorial to George, fifth and last Duke of Gordon; and several other restorations, both external and internal, mural and decorative, are being carried out by a local committee, under the advice of Mr. G. G. Scott.

J. MALCOLM.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

DR. ZERFFI delivered his thirteenth lecture on this subject at the Kensington Museum on Friday afternoon last. In this lecture he entered into what he called Greek architektonic art, or architecture in detail. There could not be the slightest doubt, he said, that the Greeks were the first who had in reality succeeded in bringing down to first principles the products of architecture, and in so doing they had evidenced a capability of creating real works of art. They surrounded space (and that is what every architect has to do) with walls, and in this they succeeded to the utmost, firstly, because they were able freely to choose their material; secondly, because they were capable of bringing that well-chosen material into beautiful and symmetrical forms; and thirdly, because they were always erecting for a certain purpose. In these conditions are included all the elements of a good building. In the beginning the Greeks used sandstone. After alluding to the use of travertine, the lecturer proceeded to say that in course of time the Greeks, as well as the Romans, used white marble. Next in importance to stone as a building material with the Greeks was wood, but by degrees wood vanished altogether, and it is only to be traced in the ceilings of the buildings, although even for ceilings it ultimately ceased to be used, as in the Athenian temples, where the roofs were of stone. The ceiling of the Temple of Ephesus was of cedar wood. The Greeks also used other materials, such as clay, chalk, and gypsum and marble dust, which they ground as stucco and called *κονιασις*. Metal formed a very great element in the construction of the temples, as many of the ornaments are traced to have been of bronze. Dr. Semper went so far as to say, in his "Art History," that the Corinthian capital was not the newest form of Greek architecture, but was as old as the Doric, and it originated in metalloteknic. As far as especially the decorative forms of the ornamental *motif* of the Corinthian capital goes, it was quite reasonable to assume that before the people learnt to carve the ornament out of stone or marble they had executed it in bronze. This supposition, said the lecturer, was not unreasonable, although he did not think it correct. Certainly there was plenty of bronze work in Greece at an early date, such as swords, ewers, shields, and armour, for such were described by Homer. A proof of this was also afforded by the Corinthian capitals of the Museion at Alexandria, which were of bronze, while the pillars were of white marble. The upper part of the acanthus leaves were of gilt bronze. Seeing that the Greeks used all the four principal materials of art—*i.e.*, the plastic, the elastic, the pliable, and the solid, we might investigate Greek architecture in all its fundamental principles. In every kind of artistic building we had two lines, the vertical and the horizontal. The use of these lines was well known to the Greeks, and they also used the curved line and the plain; this was especially the case with the cylindrical or conical columns. The great secret of the success of Greek structures consisted in one single condition—symmetry. The Greek always knew how to arrange the parts so as to bring about a beautiful total. The lecturer impressed upon his audience that they must not allow themselves to be led so far as to think that there was a kind of prescription in that symmetry, and that they must always have one and the same symmetry. That was a great mistake, and would only make the students who committed it copyists instead of self-thinking artists. They might vary that symmetry in an unlimited degree, but they must start from a certain unit. When they knew how to group around that unit, and how to produce a symmetrical building, they would succeed in that in which the Greeks so highly excelled. In speaking of the order or style of a building, the student should clearly understand what was meant by each of those terms. Many authorities said that order and style were the same—were synonymous and convertible terms—but he (the lecturer) denied the correctness of this dictum. "Style" was subjective, "order" objective. "Order" was fixed upon by an unlimited number of artists, who all followed one order. The artist working subjectively with the order created his own style. Of "orders" there were in reality but three, but there were innumerable styles. The artist should not bind himself in any way to a special "order," but in carrying out the order should create a style of his own. Speaking of proportion, the lecturer went on to say that whenever anybody told an artist to keep to proportions he told him to be as free as possible, because the artist himself had to settle what the proportions should be. Greek art was founded on beauty, and that beauty it found in freedom, however regulated by order and law, and that is everywhere the case in art. As in the Greek mythology there could be distinguished three principal orders of gods and goddesses, so the Greek architecture was divisible into three principal divisions or orders. All architectural elements are of a geometrical origin. In architecture something has to be supported and encompassed by forms, and a kind of union has to be secured between the members which support and those which are supported. As soon as a man knows how to do this he is a perfect architect; all the rest of his work is mere ornamentation. There is nothing which is more beautiful for support than a column, because it has a beauty perfect in itself, and embodying as it does the dynamic force, it gracefully interposes between the base and the plinth or architrave, representing the static element. This was most energetically expressed in the Doric order. The Ionic order was less pronounced in this respect, and the Corinthian order still less. The echinus of the Ionic capital might be cut away without any loss of even *apparent* support, but that was not the case with the Doric column. The capital of the Corinthian column was long-bodied and tapering, leading to the impression that behind it or inside of it there must be a very strong support to carry the superstructure. The Ionic capital evidenced a departure from correct principles, and this was still more the case with the Corinthian capital. The lecturer then proceeded to classify the styles in each of these three groups. Firstly, with regard to the Doric, there could be traced six different styles, viz.: (1), the so-called Proto-Doric style, in which the columns were sometimes square; (2), the Lax Archaic Doric style, of the seventh century B.C.; (3), the Stern Archaic Doric style, sixth century B.C.; (4), the Pure Doric style, fifth century B.C.; (5), the Attic-Doric style, under Pericles, a mixture of Ionic and Doric, fifth century B.C.; and (6), the Macedonian Doric style, four centuries B.C. To talk of all the different styles merely as "Doric" was incorrect and ambiguous. In the Ionic order there were three distinct styles:—(1) the simple form; (2) the richly-ornamented form, as in the temple of Polias; and (3) the compound forms, in which the Doric and Ionic were combined. In the Corinthian order we were capable of distinguishing four distinct styles, viz:—(1) the yet undecided form, half Ionic, half Corinthian, as in the temples of Phygalia and Didymæon and the Choragic monument of Lysicrates; (2) the firm settled ornament, when the two rows of acanthus leaves had been well defined, and when there was no mixture; and there were farther variations (3 and 4) in the Corinthian order, in which there were additions of trophies, winged horses, and dolphins and eagles; this was especially the case with the latter part of the Roman Corinthian architecture. Each of these orders was capable of any amount of variation to combine with the two others. The great variety of style has been the result of this triple union. The artist could avail himself of a variety of forms, and was not tied down by Vitruvian canons, by architectural guilds, by building committees, or by boards of works. He was perfectly free in the choice of his site, and that was of the highest importance. According to the nature of his site did he design his building, the treatment of designs for a building amidst rocks, trees, or on plains varying considerably, in order that the view of the building might be beautiful and harmonious from any point. Of course in a large city with three millions of inhabitants the architect could not always choose his site, but much more might be done in the selection of good sites by the Government, and municipal and other corporations, for their important public buildings. The site once selected and the order settled, the architect entered with all his heart into the execution of his work, developing a style of his own as he went along. He was untrammelled by any prescribed laws, such as are now educed and slavishly imitated. All the refined cadences, from the primitive Doric to the latest Corinthian, gave scope to the artist. Referring to the caryatides of the Erectheum, Dr. Zerffi said that there was nothing elegant in such a design, as the Greeks themselves must have perceived, for it was only in that building that this Asiatic-like notion was embodied. Respecting the leading characteristics of each of the three orders, the lecturer said that in the Doric order proportion was pre-eminent, while symmetry was the pre eminent characteristic of Ionic, the predominant quality in the Corinthian order being eurithmy. Although he had attempted to classify the various styles of the three orders, he would say that in all such classifications narrow-minded pedantry should always be avoided, lest the power of the artist's imagination should be checked, and fettered down to outward forms which he was afraid to break, and thus art would be hindered instead of promoted. Various fanciful theories had been laid down as forming a sort of royal road to the excellence attained by the Greeks in architectural design, but when carried out practically they had all resulted in failure. The lecturer concluded by explaining the inferences deduced from the triglyphs and other features of the Greek temples that such structures must have been formerly executed in wood, and by expressing his dissent from certain far-fetched theories of archæologists, such as, for instance, that the spaces between the triglyphs were formerly windows.

The contract for the construction of the new docks and the extension of the canal near Sharpness has been let to Mr. George Wythes, of Bickley Park, Kent.

ON THE MODES OF DECORATIVE TREATMENT ADAPTED TO VARIOUS MATERIALS.*

(*Concluded from page* 46.)

CAST-IRON

MAY be considered, for art purposes, an abnormal material; yet its extensive use obliges us to consider what rules should guide our treatment of it. We must regard its conditions as somewhat similar to those of bronze, without the latter's capacity for high finish. The coarse surface resulting from the casting is destructive of delicate detail, nor does it readily admit of sufficient finish. The character of the detail must therefore be regulated by the nature of the surface as it comes from the mould, and should be adapted to the requirements of castings. If these conditions are carefully studied very satisfactory results may be obtained. It is only when cast-iron affects to imitate wrought-iron or some other substance that it fails, disagreeably, to take its right place as a valuable material.

BRONZE

may perhaps be considered as occupying the foremost place among metals for purposes of art. Its close texture admits of the highest finish, resulting in softened high lights, the most favourable for the display of surface form. It therefore lends itself admirably to either delicate or vigorous relief. The effect of the relief is often heightened by the brightness of the metal, where its prominences are subjected to abrasion. Although, like cast-iron, it is turned out of a mould, it differs materially in more than one respect. It has not the hard, brittle nature of cast-iron, but, on the contrary, is, to a certain limited extent, ductile and elastic—qualities which enable its treatment to resemble more nearly that of wrought metal when such is deemed desirable. But beyond this it is admirably adapted for receiving finish at the hands of the chaser, who may expend upon it, with advantage, almost any labour or care that the size or nature of the object admit of. Perhaps no material is so effective in work both small and large. From the great gates of the Florence Baptistery to the minute medallions wrought by Japanese artists, bronze seems equally to lend itself to the object, and equally to satisfy the just requirements of art. In the latter instance it has received the highest conceivable finish, in the former only so slight a finish as the large scale and exposed situation require. But in all cases, whatever the size of the work, the plain surfaces should be carefully finished, so that the spectator may recognise the fine texture and beauty of the material. For the same reason, the contour of mouldings should be refined, and should be relieved by acute arrises or fine fillets. True, the dark colour makes requisite deep cutting or bold modelling where emphasis is necessary, or where the parts are in shadow, but even here coarseness must be carefully avoided, and the sharpest finish given to all edges. A dull, blurred edge is destructive of metallic effect, and herein lies one of the leading causes of failure among our London examples of bronze statuary. One and all, they never get beyond the clay in which the model was designed. Turn from these to such works as the equestrian statue of Colleone at Venice, or the great kingly figures which stand round the tomb of Maximilian at Innsbruck. Full-sized copies of these are in the Crystal Palace. What a contrast! I defy the idea of plastic clay ever to enter one's head when regarding these examples. Apart from the magnificent vigour of their design, there is a *metallic finish* about them, bold though it be, from head to foot. Sharp edges are preserved, both in outline and detail, giving an unmistakeable sparkle and spirit to the whole, which would be entirely lost were the sharp lights rounded down or "smeared" away as we see them in Trafalgar-square examples. Can anybody point to a single London statue (save that of Charles II.) which might not just as well have been cast in iron as in the exquisite material of which it displays such a profound unconsciousness on the part of the artist? Take our most recent and most valued acquisition—the Nelson lions. Where do we find the spirit of bronze? Where are the crisp bright lights and the sharp deep cuttings, or the silky gleam of surface, which all speak of metal? Not in the mane, assuredly! Yet how valuable would have been the bright streaks of light in explaining the intended object! Look at the paws; how innocent of everything but the marks of the tool, *not* with which the bronze was finished, but with which the clay was moulded—all too faithfully reproduced in the casting. Had they been of terra-cotta, these modeller's toolings would have been well; but when we are working a valuable metal, the wretched sand or clay which we may happen to use in the process should be unknown to the spectator. It is *not* the ready but "smeary" moulding tool that should be evident to remind him that this is but a costly reproduction from a baser model, but it is the sharp file and keener graver the skilful handling of which he is to recognise. It is the *ultimate* work, the finished, hard, gleaming metal which is to show the artist's hand. The clay, and all that belongs to it, have no more business to be seen than the painter's lay figure. Herein lies the gist of all that I am trying to say, and, half against my will, I have selected this example (the noble design of which I thoroughly appreciate) precisely because its excellences are apt to lead the student to forget its defect—material ignored.

In such bronze objects as include the use of mouldings, these should, as I have already said, present fine profiles. By this I do not mean that the actual size of the mouldings need be limited, but that the flow of the lines should be such as to present gradual and softened curves where broad lights are required, the edges being kept sharp and the shadows dark and well-defined. To this latter end we often find in the best works the moulding highly concave on its underside, by which means the broad sharp edge is brought sharply against dark shadow. Examples of this are frequent among the elegant candelabra and other objects found at Herculaneum and Pompeii. We may also observe in these works how the mouldings are here and there wrought to an extreme tenuity, thereby assisting the eye to recognise the tough strength of the metal. Occasionally, too much delicacy is given by the occurrence of very very fine fillets—mere threads—upon the profile. For examples of excellent treatment of ornamental work in bronze on a large scale, we may take Allesandro Leopardi's grand standard sockets at Venice. In them we find the boldest treatment of contour or form combined with a masterly finish of the details. Modern French sculptors and artists have well studied the effects of bronze as a material, which, indeed, may be considered the one which of late years the French have most completely made their own, simply because their artists and workmen are at the trouble of studying their material, and adapting the nature of the treatment to the due expression of its character.

PEWTER.

Before passing to the precious metals, we may pause for a moment to consider that exquisite works have been produced by François Briot, and others, in so common a metal as pewter. So ductile a material is of course very readily répoussé, and the subsequent chasing is much more easily executed than in the harder metals. Lead or pewter is used for the finished models from which the smaller kinds of ornamental detail are cast in brass or bronze. These models are often far more beautifully finished than the greater part of the work cast from them, and there can be no question that these substances offer great facilities to the artist. The drawback is that their softness renders them very liable to injury, so that it becomes a question whether the harder and more valuable material does not more than repay the additional labour which it demands.

SILVER.

In silver we have a material which, apart from its intrinsic value, possesses many qualities valuable to the artist. It is far more ductile than bronze, and at the same time has natural hardness sufficient to resist any ordinary risks of wear. This hardness may be increased by alloy. In addition it is exceedingly durable, and admits of the highest finish. It is also open to two distinct methods of treatment, which may be used separately or in combination. If polished or burnished, its whiteness and strong high lights preclude delicate work in the detail; at the same time, these qualities result in inconceivable splendour of effect when boldly treated, especially in objects which are made to depend upon form in such a way as to exhibit the burnished surface to advantage. Bold bossed work is very effective, and may be used with excellent results either alone or in combination with engraving or répoussé relief. A matted ground is then valuable to the latter. Engraving, to tell well on bright silver, must be pretty boldly executed. The lights are otherwise lost in the overlapping reflected rays of light shed from the surrounding surface. For art purposes, the most favourable form of silver is that known as "oxidised," in which the extreme whiteness and brilliancy of surface are subdued. It then possesses the finer qualifications of bronze in a higher degree, and the light gray colour which it presents, together with the fine surface and softened lights, render it the best of all materials for delicate and highly-finished relief. In fact, the chasing may be as fine as the artist can bestow, nor need we fear that his labours will be lost. Many valuable modern works have been executed in this country, though by foreign artists, and some excellent reproductions have been made in *facsimile* by the electrotype process. The most beautiful modern specimens of répoussé silver, however, which I remember, were exhibited in 1867 by Faunière, of Paris, who, in a table service (said to have been designed by an amateur for his own use) combined excellence of form and design with most admirable treatment in execution. It is satisfactory to find that one of the English artisans whose reports were published by the Society of Arts appreciated the remarkable excellence of the works from this *atelier*. "Other exhibitors," he says, "show some good pieces," but in Faunière's case "I think it is impossible to discover one piece of inferior work, while many are real master-pieces." "Party-gilding" and "damascening" may both be used on dull silver with good effect, the main point to care for being to avoid confusion. Engraving may be used with both, and if the surface is not polished, may be as fine or as elaborate as may be desired. A hatched or matted ground, judiciously used, often adds greatly to the effect of low relief, or may sometimes be used to show a flat ornament with engraved outline.

GOLD,

the most valuable and the handsomest of natural products in general use, is, by reason of its powerful colour and strong lights, not very favourable to the display of delicate modulations of surface. In large objects, highly bossed work, bold relief, or low relief set off by a mat ground, tell well, as also does engraving, whether fine or bold. Whilst possessing great strength and tenacity, it is extremely ductile, and in its native state bends very readily. These qualities sufficiently account for the extent to which the ancient and oriental goldsmiths used fine twisted wire in the ornamentation of their jewellery. Angular or very sharp sections are not desirable, the latter giving a steel-like character to the subject; whilst thick, square edges have a "strong" effect. Slightly rounded edges and tolerably bold profiles seem best to suit the characteristics of gold. Very thin sharp edges seem to detract from the value, and look poor. Very fine reliefs, rising abruptly from its ground (as the wire ornament already mentioned) always tell very happily in gold, because, although ever so delicate, it provides itself a fine outline, and this is what gold always seems to demand. On this account répoussé work in plain gold must always rise more suddenly from its ground than would be necessary with bronze or dull silver; but being once provided with this natural outline, the execution of the raised work should be rounded and soft, not abrupt and angular. Anything like abrupt contrasts of light and shade will detract from the effect of work in gold. A certain *repose* is essential to the solid beauty of the material, so long as we are depending on the gold alone. If, however, we are merely using the gold as a setting for some more precious object (such as jewels), the rule may be modified. So far I have been speaking of gold having the fine dull surface natural to it in its native state. For almost all art purposes this has the most agreeable finish. At the same time we must not ignore the burnisher, which, when used with judgment, may produce excellent effects by contrasting the bright and dull surfaces, and so giving special emphasis to certain parts of the design. Burnished gold alone has rarely so good an effect. Gold has the peculiar property of harmonising colours. It does so to an extent that only those who have tried it can believe, and at the same time clears and purifies each colour it surrounds. Precious stones are therefore always seen to advantage in a gold setting, and both they and coloured enamels may be used to give point to a design, even where they are only employed with the secondary intention. From gold to

* Read before the Architectural Association on the 13th inst. by Mr. J. D. CRACE.

GILDING

is an easy transition. Gilt metal may be considered as, in the main, subject to the same rules as gold; but the same delicacy of treatment and high finish are not demanded. The relief must always be strong enough to clear itself, unless it be assisted by the burnisher, of which a more free use may be made. Gilding on wood, or other similar material, may be made more or less effective by judgment in execution to a far greater extent than would at first sight appear. The judicious or injudicious disposition of the burnisher may make or mar the whole piece. Surfaces which are much cut up should never feel the burnisher, which should be confined to such parts as present evenly-rounded or flat surfaces. The burnished parts should always be so placed as to assist in expressing the design. Carved surfaces should be in dull gold, care being taken that the "preparation" does not smooth away all the spirit from the work. When only a portion of the object is gilt, and the remainder shows wood as its material, I prefer that the gilt parts should also exhibit the texture of the wood.

FLAT SURFACE DECORATION IN COLOUR.

The same rules which we have been applying to the treatment of ornament in the solid apply in a different way to the coloured treatment of various surfaces. Here, similarly, the eye must be judiciously led to forget the imperfections of the material where it is imperfect, or to follow its excellence if it be excellent. A rough or irregular surface of wall must, in the first place, be absolutely without gloss, and its decoration must then be so carried out as to lead away from the considerations of surface. Continuous straight lines or fine curves are to be shunned, nor is delicate finish desirable. A certain breadth of effect and execution must be maintained, and the forms of ornament selected must be such as not readily to betray the slight distortions caused by uneven surfaces, but to lead the eye to follow the intention of their own forms. On the other hand, where the wall presents a singularly fine and perfect surface, this may be done justice to and explained, firstly, by making the coloured ground carefully even in tone and texture. It may even be thought desirable to maintain a slight gloss, but this must not be excessive. Fine details and strong lines may be used to any extent required, and the finish need only be limited by the skill of the artist. In this, however, a distinction must be observed as to the execution of those parts which are mere ornament and those which partake rather of the nature of pictorial art. The former are intended to add to the general effect of the room or building, and should therefore be executed in such a manner as to explain themselves and answer their end when viewed as part of the whole. However finely executed, the lights must be sharply preserved, and not toned off too gradually to the shades. A certain crisp solidity of touch, with a precision of intention, are indispensable, though they need never become obtrusive. I cannot do better than point to the decorations of Pompeii for examples of the execution of decorative ornament on a fine surface. When, however, pictorial art is introduced, I am far from desiring to limit the finish or to dictate the style or method of execution. The artist will, of course, comply with the condition that the general tone of colour and force of effect be such as to harmonise with the rest and assist the general result. Having done this, it remains with him alone to decide whether his work shall be most admired at a distance of one yard or five yards. It occupies the position of a gem in a fine setting, and invites admiration on its own account as well as by adding to the value of the whole. Yet, even with this freedom, the painter who has never painted for any surrounding but a gilt frame will find that he has much to learn before he can satisfactorily ally himself to the architect.

STAINED GLASS.

We have been considering how far the treatment of coloured ornament may be varied to meet the necessities of the surface to which it is applied, the variation being rendered necessary by the way in which the light, falling on those surfaces, affects the appearance of the ornamentation, and *vice versa*. We have, however, in stained glass windows, coloured ornament applied under totally different conditions. In wall treatment we had to *explain the surface*; but here we have nothing to do with surface, of which the eye can take no knowledge, the light being transmitted. It can, however, take note of outline, form, and colour, therefore especial care must be taken in respect of these elements of beauty. The leading forms must not only in themselves be pleasing, but must be so clearly defined as to be distinguished, in spite of the flood of light which pours through, the rays of which spread and overlap each other. But it is in dealing with the question of colour that the treatment of stained glass is really put to the proof. We have not only to arrange our colours harmoniously, but to make the most of our beautiful material. It is in the jewel-like appearance and play of colour that the great charm of stained glass lies, and our study should be to enhance, as far as possible, this special beauty. If we observe carefully the most admirable works of the old artists in stained glass, we shall find that one important means to their success lay in the skilful use which they made of the irregularity of their material. *With colours obtained by transmitted light, those are richest which vary most in depth.* This is an axiom which workers in translucent material (be it glass or enamel, or what not) should never forget. It is their first condition of success. Such homely illustrations as a decanter of claret, or a spoonful of currant jelly on a white plate, will explain my meaning as well as any. If the wine were in a flat vessel of uniform depth, the colour would be there, but half its rich play and flashing glow would be gone, for it derives these from the varied diameter of the vessel. So with the jelly, the colour of which is displayed (as in enamel) by the light reflected from its ground, the plate. If spread in an even coating, the colour is still beautiful, but the rich palpitating effect is no longer there. In large surfaces of one colour, the masses should be made up of several pieces of varying depth. In small spaces the varied thickness of the glass itself must be depended on. And where, as in a border, the same colour is repeated to a considerable extent, so far from matching each piece to the other, the skilful artist will seek how to *vary* them with most effect Many of our best glass artists are well aware of this, but until the workman himself appreciates and understands how thus to give value to his work by studying his material, advance will be slow. Still, in knowledge of their material, the English stained glass workers of to-day surpass all their foreign rivals. Whatever excellence of pictorial design the much-vaunted "Munich windows" may possess, they betray absolute ignorance of the treatment of material. They are mere transparencies, and but for their greater (almost unfortunate) permanency, might just as well be painted on oiled canvas as on glass, of which they exhibit not a single characteristic. (Applause).

CONCLUSION.

We have now glanced at several of those materials which are in most general use for the purposes of art, especially of such arts as are most closely allied to the architect. In thus rapidly surveying the leading peculiarities of each material, I have endeavoured to point out that, although much may be done in *design*, much also remains in the power of the artist or workman under whose hands the crude lifeless material is wrought into the living treasure. It lies with him, not only to do justice to the conception of his own art in his own brain, but, in so doing, to seek for all the assistance and all the power of expression which he may derive from the substance which he has selected from the rich gifts of his mother earth.

A discussion ensued in which Messrs. Potter, Phené Spiers, H. W. Lonsdale, Lewis F. Day, Staunus, and J. G. Crace, took part, and the thanks of the Association were tendered to Mr. Crace for his instructive paper.

THE OLD AND NEW GENERAL POST-OFFICE.

THE "old and experienced official in Her Majesty's Office of Works" has, in the additions to the old Post-office, and in the design for the new building now being erected opposite to it, given us an idea of the amount of respect paid to the existing works of *architects*, and also the art quality of the productions to be expected under the Ayrton administration of his department; we say *respect* for the works of architects, because it is pretty generally understood, outside the Office of Works, that this is due from an architect when he has to make additions to, or alterations in, the work of a predecessor, and when that predecessor happens to be a man of the architectural "calibre" of Sir Robert Smirke, we should have imagined that "an old and experienced official" would not have disregarded such a rule; as an illustration, he need have gone no further than Somerset House to have witnessed the attention paid by Sir James Pennethorne—consistent with the requirements of the new additions—to the work of Sir William Chambers, the result being highly creditable to Sir James, and at the same time in harmony with the old building. We, of course, are not comparing the two as regards magnitude, but this first work under the—we may say—new system should not pass by unnoticed.

Externally the new addition seems to be central with and set back from the portico of the old building, and is higher than the top of the pediment, and consists of an erection presenting to the front a plain face of *cement work* with sloped sides, coped with stone, forming the gable end—we may term it—of the addition, which has side lights and seemingly skylights below; the two sloped sides of the end do not even agree, and there is an entire absence of intention to make the new work harmonize with the old. The face work of *cement* is certainly inexcusable. As a roof to an isolated workshop the work would be passable, but here the result is a spoliation of the dignity of the building by no means creditable to the "experienced official." A good view of it may be obtained from the corner of Newgate-street and Aldersgate-street, and we recommend our readers to visit the spot and see with what care our important buildings are treated.

As regards the new building, judging from the design as published by a contemporary, it is beneath criticism. We challenge the most observant critic to point out throughout the design one particle of originality, excepting, perhaps, the absurd rustication of the central columns supporting those of the pediment above; the design of the central door, of which a detail is given, is disgraceful, and the whole, omitting the central feature, might, perhaps, pass for a row of second-class dwelling-houses; but as a design for an important public building, is an insult to the art architects of the period. W. W.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.

ON Thursday evening, 19th inst., the thirteenth session of this society was inaugurated by a *conversazione* at the Suffolk-street Gallery, Pall Mall, which was kindly lent for the occasion by the Council of the Society of British Artists. The Society for the Encouragement of the Fine Arts was founded in December, 1858. Its objects are indicated in its title. Through its agency, a point of agreeable re-union between the artist and the amateur has been established, where their mutual interests may be made known and cared for, and the principles which should regulate the arts in their important mission discussed and disseminated. The scheme of the Society, so far as it has been developed, includes exhibitions of works of art, when papers are read and discussions take place upon questions of art; lectures on all branches of the fine arts, when discussions are invited; and *conversazioni*, with performances of vocal and instrumental music. The opening *conversazione* was very numerously attended. In the course of the evening Dr. Heinemann, professor and lecturer at the Crystal Palace, delivered an address on the principles and objects of the Society, and a well-selected programme of vocal and instrumental music was gone through, under the direction of Mr. Alfred Gilbert, the hon. musical director of the Society. The choice specimens of art upon the walls of the various rooms comprising the gallery of the Society of British Artists were not the least attractive features of the evening's proceedings.

ART AND ITS BELONGINGS.

ART and its belongings, says Mr. Muckley, head master of the Manchester School of Art, require to be brought repeatedly before the notice of the English public, more than any other department of education, and if we are to succeed, it is necessary for assurances of its value to be insisted on continually by those who understand it best. The love of the beautiful in Art has yet to be recognised amongst us as one of the subtle and for the most part hidden instincts of our nature, and to those who can cultivate it from proper motives new and

continuing sources of delight and happiness it will bring as a reward.

With the earliest people of our species, Art instincts and a yearning beyond the bare wants of the flesh have always been manifested in a most extraordinary way, and the expressions of Art feeling which they have evinced in divers forms have been of a perfect kind, seldom erring either as to quantity, form, or colour; and just as the bird selects the never-varying materials to build its beautiful nest, with a knowledge of which we know nothing, just so was it with the earliest tribes of our race—the necessities of existence and the useful were certainly the first things for their consideration, and then the ornamental.

In his migratory movements, the rudest appliances to propel the canoe of the savage were first invented, and as soon as this condition was met, he carved a thousand beautiful devices on his boat oar. In search for food in the chase, he handsomely decorated his weapons, and the handle of his hunting knife was ornamented in a perfect manner and according to the highest instinctive expression of his nature, but not until he had killed and eaten.

And so it is, I am willing to believe, with regard to our own position in the present era; the necessity for the useful up to a very recent period has been the all-absorbing theme, and that we do not as a nation repudiate the real and living worth of the beautiful I am convinced, but on the contrary, I feel certain the time has now come when this country, individually, will desire a full development of the higher instincts of our being. The manifold form of its seekings may perhaps be vague, and to many appear unmeaning; nevertheless, I do feel it is in your power, and in the power of a few others in this city, to lead forward the cause of Art, to raise the standard of its appreciation as connected with the various branches of industry under our control, and the familiar objects intended to be in and about our dwellings: in short, to weave the golden thread through the lives of those with whom we live, and for which their children's children will thank you.

THE FOUNDATIONS FOR THE NEW LAW COURTS.

The following tenders have been received for the foundations for the New Law Courts:—

Gammon & Sons	£ 68347
Holmes & Nichol	66900
Lucas Brothers	65719
Myers & Sons	57435
Lee & Sons	56500
Taylor Johnson & Smith	54240
Markwick & Thurgood	49000
Holland & Hannen	48300
Kirk	48182
Webster	47500
Cubitt & Co.	46555
Brass	46240
Trollope & Sons	45473
Perry	44973
Browne & Robinson	44680
Hill, Kiddel & Waldram	42750
Higgs	41987
Henshaw (too late)	38350
Axford & Whillier	37175
Dove Brothers	36755

Certainly tendering must be a game of chance. In fact, it looks as if it were as bad as betting. It will be seen by the above that there was only the trifling sum of about £32,000 difference in estimating for the foundations of the Law Courts.

Building Intelligence.

CHURCHES AND CHAPELS.

BOSCASTLE, CORNWALL.—Minster church has just been reopened, after a general restoration under Mr. St. Aubyn, architect, of London. The galleries have been removed, and low free seats have taken the place of the former high pews. The pulpit has been removed to another position, and the harmonium and singers placed in the chancel, which has been restored at the expense of the rector, while the general restoration of Minster church has been effected at the sole expense of the lady of the manor, Miss Hellyar, to whom also belongs the advowson and patronage of the livings of Forrabury and Minster. Mr. Burt, of Launceston, was the contractor.

EDINBURGH.—A new oak reredos has just been erected in St. John's, Princes'-street. The design consists of a centre portion above the altar, and two side pieces connecting the centre with the east pillars of the nave. The centre portion is about 8ft. in height above the super-altar, and 7ft. long, and is formed of three richly-traceried arches, each flanked with an elaborately moulded and panelled buttress, and finished on the top with a deeply carved and moulded cornice and open cresting. The buttresses are carried through the cornice, and terminate in gableted and crocketted pinnacles. The three panels within the three arches are at present covered temporarily with red cloth, corresponding with that of the altar below, but it is intended that they shall be filled in with an ornamental design of some kind, probably on a dead gold ground, and it is contemplated also to bring out the leading lines of the design by gilding, as was done so successfully with the traceried ceiling of the nave. The work, which has been entirely executed in solid American oak, has been carried out by Messrs. Davidson & Read, of Frederick-street, from the designs of Messrs. Peddie & Kinnear, architects.

FARRINGDON, DEVON.—The parish church has been entirely rebuilt from the designs of Mr. W. White, F.S.A., of Wimpole-street, London, and was consecrated by the Lord Bishop of the Diocese on the 14th inst. The parish is a small one, containing little over 300 inhabitants. The style of the building is transition from First to Second Pointed, and consists of chancel and chancel aisle, nave and north aisle in three bays, the easternmost bay being carried out transeptally, a south porch and western tower, with an oak shingle spire capable of receiving four bells, but at present there is only one. The spire is surmounted by a large vane. We believe there is only one other shingle spire in Devonshire, that at West Worlington. The walls are built of local stone, with Ham Hill dressings, and the interior is lined with brick. A good deal of the Beer stone of the old building has been used and mixed with the Killerton stone; it has a very good effect. The roof, which is an open deal one, is covered with plain tiles. Accommodation is provided for 150. Chairs are provided, and the floor underneath them is composed of wood blocks, on a principle of the architect's, and as adopted latterly by him at Lankey Church, near Barnstaple. In the passage up the centre of the nave, the old mural stones that were in the ancient building have been again laid down, but they are lined with ornamental tiles. On the chancel floor Minton's tiles of considerable richness have been laid. The chancel is lighted by three stained glass windows, the gift of the Ellacombe family, which has long been connected with the parish, as the monuments on the walls testify. The east window is a three-light one, and represents the Nativity, Crucifixion, Resurrection, and Ascension. This window is the gift of General Ellacombe. The other two are small two-light ones, and are placed on the south side. Ward & Hughes of London supplied them. The choir stalls are of oak, as also is the pulpit, which is raised scarcely 18in. above the floor. The altar is formed of a panelled front, with detached shafts carrying a massive marble slab, over which is a marble cross. The old Norman font, which was very much dilapidated, has been carefully restored. It is Late Norman in character, and the restoration has been carried out in accordance with the fine example of a similar date existing in S. Mary's Steps Church, Exeter. It has a massive oak cover, which is new. There is a little stone carving upon the building, which, as the meritorious effort of an amateur, deserves a passing mention; it has been executed by the clerk of works, Mr. George Vickery, during his spare hours. Mr. Mayell, of London, was the builder, and the total cost of the work has been about £1,350. The farmers of the parish provided the cartage for drawing the materials free of expense.

HACKNESS.—S. Peter's Church, Hackness, near Scarboro' was re-opened on the 18th inst., after restoration by Mr. Ewan Christian. Under his direction the galleries have been taken down, all the plaster removed from the walls; the seats, which were narrow and inconvenient, replaced by handsome oak sittings, more conveniently arranged; the old vestry thrown into the church and a new vestry constructed. The ceilings have been removed and open roofs substituted, the roof of the chancel being of higher pitch than before. The wall of the south aisle, being very dilapidated, has been taken down and re-built. In the chancel, an old window which was blocked up has been opened out, and another old window has been restored, and all the windows have been re-glazed, some new ones being inserted in the north aisle. The contractors for the work were the Messrs. Pedbury, of Selby.

HULL.—On Saturday last the new Church of S. Silas, Hull, was consecrated. The building contains sitting accommodation for 660 persons, and consists of nave, with north and south aisles, chancel, organ chamber, and vestry, and is built in the Gothic style of the twelfth century, from the designs and under the superintendence of Mr. Samuel Musgrave, Hull. The church is constructed of bricks and faced with red stocks, with bands of blue Staffordshire bricks, tracery, and other dressings. Ham Hill stone has been used. The interior of the church has Bath stone columns, with moulded caps and bases, and parti-coloured brick arches and stone labels to the nave arcade. The chancel has an apsidal termination, and has moulded brick arch and stone sub-arch resting on bold moulded corbels and shafts of Bath stone, with carved capitals and moulded annulets and bases. The contractor for the whole of the works was Mr. Musgrave, of Hull.

LYNMOUTH, NORTH DEVON.—The new church of S. John the Baptist, now erecting from the designs of Mr. E. Dolby, of Abingdon, near Oxford, is nearly complete, and is expected very shortly to be available for use. The style is Early in character, and the building consists of nave with south aisle, apse, and organ chamber, with porch at north-west corner of nave. There is a bell-turret for two bells on the western gable. The edifice is built of limestone, and the same material is displayed on the inside as well as outside walls. The dressings of the exterior are of Ham Hill stone, and those of the interior of Bath, Ham Hill, and Forest of Dean stones. There is a stone groined roof to the apse, springing off moulded and carved corbels, the roofs of nave and aisle being of open timber. The windows, excepting those on the north of nave, are small lancet ones, with a very deep splay. An arcade of three bays divides the nave and aisle, the capitals of which are somewhat richly carved with conventional foliage. The whole of the floors are laid with Maw's tiles. The stalls are of oak, as also is the altar-table, which latter is raised by a series of steps to some altitude above the level of the nave. The rest of the church is to be seated with chairs, excepting only in the part used by the school children, for whom deal benches are provided. The whole of the work is being executed by Messrs. Oliver and Son, of Barnstaple, at a cost of about £2,000. The carving is by Hems, of Exeter. Mr. Lewis officiated as clerk of works during the earlier part of the work, but latterly the services of a clerk of works have been dispensed with.

WILLESDEN.—Two handsome memorials have lately been erected in the parish church of S. Mary, Willesden, which greatly improve the chancel. The one is a reredos of Caen stone and various coloured marbles, with light open tracery showing the east window at the back, with the words, "Holy, holy, holy, Lord God of Hosts," in gold letters on a blue ground beneath the window. The other is a very rich encaustic and mosaic pavement for the sacrarium. Both memorials are from the designs of Mr. Tarver, architect, and are given by the Mason family and Mrs. Metcalfe respectively.

THE HORSE SHOE CLOISTERS, WINDSOR CASTLE,—The restoration of this ancient pile of buildings at the west end of S. George's Chapel, Windsor Castle, is progressing rapidly. The herring-bone brickwork of the houses, divided into panels by oak beams, will, when finished, present a picturesque contrast to the rest of the Castle architecture. The architect is Mr. G. G. Scott.

PRESERVING WOOD FROM DECAY.—By the process of Mr. Archibald B. Tripler, of New Orleans, wood is said to be preserved from decay in the following manner:—The wood is cut into two or more equal parts or slabs. These pieces are bored at equal distances to receive the trenails to unite them, and they are immersed in a solution of coal-tar and powdered charcoal, either hot or cold, in equal or unequal parts, which not only thoroughly impregnates the slabs with carbon, but coats the surface with an adhesive material, so that when put together their adjacent sides will adhere together, and form interior partitions or walls of antiseptic or preservative agents, extending from one end of each slab to the other. These slabs are then united with trenails, or double pins, in such a manner as to lock them as firmly and solidly as if they were one piece. The timber thus prepared is immersed in a solution consisting of asphaltum, or mineral pitch, 80 parts; sulphur, 5 parts; arsenic, 5 parts; coal-tar, 5 parts; powdered charcoal, 5 parts;—in all, 100 parts. This solution will cover the surface, and fill up the joints and crevices between the slabs, rendering them impervious to water, and effectually preventing atmospheric decomposition by insulating it from the decaying influences of the elements.

THE USE OF PHOTOGRAPHY TO THE ARCHITECT AND ENGINEER.

THE use of photography to the engineer and architect is not confined to the purchase of photographs, however good they may be. It certainly never can become a substitute for sketching, for the free use of the pencil is all important. Yet, as an aid, it is of great value. "What student," asks Mr. E. L. Williams in the *British Journal of Photography* "could in a week bring home six dozen sketches of details of cathedrals and churches? Yet, on one occasion, working with dry plates in France, I had no difficulty in doing so. From my commencement with the calotype process in 1848, to the present day, the camera has been the companion of my holiday tours, and has often proved of great value in my professional pursuits. That silver prints need not necessarily fade I consider proved by those printed by myself twenty years since being now quite perfect. Some of the most eminent engineers have their works photographed weekly or monthly; and all who saw the collection taken by the Royal Engineers at the late Exhibion in Condnit-street must have seen the great value of such absolntely correct memorials of the resistance of iron targets to shot. I do not pretend to determine the vexed question of dry *versus* wet plates, except to remark that I think an amateur should nse both. Each has its advantage and each its inconvenience, and a knowledge of each process should be gained. When weight of baggage is no object, and help is at hand, I prefer the wet process, taking care to use a large roomy tent with a camp-stool. In developing a pictnre we want our wits about us—an improbable contingency when working in a stifling atmosphero and nearly tired out. A good dry process has this great advantage to the amateur photographer—that he can purchase the plates ready for use, or, still better, prepare them himself in his leisure time. At a favourable opportunity they can bo exposed and developed when convenient. The Liverpool Company's dry plates are excellent, but for large pictures I prefer the collodio-albumen process, which with the gallic acid wash recommended by Major Rnssell in the *Journal of the Photographic Society* for July, 1858, and since often re-discovered—will enable plates to be prepared that I have proved will keep for years.

A preliminary coating of diluted albumen prevents all chance of blistering, and no trouble ever arises from the state of the silver bath. The aceto-nitrate bath used for final sensitising will do for the first bath if many plates are not required, when it is best to use two baths, the first only slightly acid. With care in preparation, and full exposure, the resnlts are certain. No large dry-plate work has yet been exhibited equal to that of Mr. Mudd, Mr. Wardley, and Mr. Sanderson by this process, and large plates are the crucial test of any method.

After many years' experience I can recommend to the engineer or architect wishing to try his hand at photography to master the wet process thoronghly, and then try the collodio-albumen process of Dr. Tanpenôt."

ASSOCIATED ARTS INSTITUTE.—A meeting for discussion was held at 9, Condnit-street, on Saturday evening last, Mr. Andrew B. Donaldson in the chair. The subject introduced by Mr. H. C. Boyes, was "That Archæological Accuracy is neither Necessary nor Desirable in Art." Mr. Boyes maintained that anything which tended to confine the artist within certain limits, and to bind him down to definite accessories, must inevitably weaken and cripple the originality of his art. He would not have him ignorant of archæology, but he would have him prove himself independent of it. Mr. Michael, in reply, said that he could readily refute the arguments of Mr. Boyes by that gentleman's own words. He had admitted that he would have artists acquainted with this study, and thus it became merely a matter of degree as to how far they were to avail themselves of their knowledge. Mr. Michael pointed out further that archæology had been of late years so much popularized that it was a matter of impossibility for an artist either intentionally or ignorantly to disregard it in his works. In the discussion which ensued, Mr. Boyes's opinions were shared by Messrs. Wilson, Day, Redgrave, Ridge, and Donaldson; while Messrs. Phillips, J. F. Boyes, and Hewitt, sided with Mr. Michael. The members present were then called upon to record their votes on the question, and the motion was lost by a majority of one vote.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

To OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—E. H., S. & Co., W. E., J. R. S., W. & S. & Co, J. P., W. & Co., J. V., J. H. S., E. G. D., J. D., E. P.

SNIDGER.—You are to be pitied. The publication of such a letter would, however, do no good.

W. W. BETHELL.—Apply to Whiteman & Bass.

W. H. B.—More suitable to a Roman Catholic or High Church paper.

J. CALLINGHAM.—We venture to say that the writer of such a letter could not write a good book.

T. ENGALL.—We cannot insert answers to "Intercommunication" questions which are merely advertisements.

GEO. VICKERY.—Your shilling's worth of stamps are handed over to the *English Mechanic* Life Boat Fund.

MONUMENTS OF ART.—You will see that we have given the first of the series this week.

HENRY WALKER.—Drawing at the lithographers.

Correspondence.

"J. B. F." ON SHARP BUILDERS' CLERKS.

(*To the Editor of the* BUILDING NEWS.)

SIR,—It is gratifying to find that "J. B. F.," in his last letter, speaks with a little more consideration for "sharp builders' clerks," and that he accepts the fact that the public sanction their existence and practice by largely employing them. He seems, too, to be even willing to admit them to the ranks of the profession, provided that they previously prepare themselves for the high honour by "careful study." The scheme proposed for effecting this great change is, to say the least of it, a little hazy, and not easily applied to men who are at present in the enjoyment of a remunerative practice, or to those who have only just commenced the course which gives "J. B. F." such annoyance.

The effort to show that there is no distinetion between the professional positions of the lawyer, the doctor, and the architect, affords a very significant illustration of the disease with which the profession is infected. The comparison does not hold for a moment. Issues of such vast and vital consequence frequently result from the labours of the lawyer and the doctor that no client or patient would ever dream of employing incompetent persons. A mistake might be ruinous, perhaps fatal; and in every way their works have a direct responsibility and importance, plainly, and often painfully, perceptible to their employers. The architect can never arrive at this peculiar stage, for the very simple reason that the public consider him as a kind of artist of a business-like character, stripped of the sentimental or romantic associations which usually surround the national conception of painters, &c. His work is not of the kind that appeals strongly to the fears or interests of his client. Even his blunders do not seriously affect his patrons, because he generally succeeds in laying the blame and the cost of them on the shoulders of his builder or contractor. I maintain, therefore, that there is a wide difference between the professions in question; and to prove that my view is the same as that adopted by the public I need only refer to the complaints of "J. B. F." himself. Such a letter as his would be impossible were it otherwise. Architects denounce with much praiseworthy vigour all kinds of "shams;" but the most injurious "sham" in the whole range of architecture is the baseless pretentiousness which assumes to itself a position to which it can never be entitled.

If these "sharp builders' clerks" give uneasiness to the professional gentlemen, let them adopt the tactics of our artists by producing work that cannot be equalled by any amateur or clerk whatever; let them cast aside the conceit which besets them, and look to their own efforts for protection, instead of uselessly waiting for the "legal restrictions" they can never get. When they become wise enough to do this, the beginning of the end of the objectionable "clerks" may be expected, and not before.—I am &c. READER.

KITCHEN BOILERS.

SIR,—In answer to your correspondent, J. W. Randle, p. 56, perhaps you will kindly allow me to make the following remarks. A gas stove at cold-water cistern may keep it from freezing, but may not have the slightest effect in preventing the boiler from bursting, as Mr. Randle justly says. If the expense be not too great, the idea of wrapping felt round the cold pipe going into the boiler, as well as round the hot or expansion pipe coming out of it, is the best. Although these pipes may not be near an external wall, yet they sometimes come in contact with a cold air draught, which in frosty weather may freeze them up at that particular place; consequently, if the water in the boiler begins to boil, the steam is checked in its passage up the expansion pipe, and then the boiler bursts. It is neither a presumed cold stone wall, nor a brick one either, that would disturb me, but the cold air, and especially cold air in motion; which latter will sometimes freeze up a pipe, or rather the water in it, at only a few feet from the kitchen fireplace. A good preventive, if the water be plentiful, is to cause one of the hot-water cranes to trickle a little during the frost both night and day, which by keeping up a slight motion in the pipes does good; only watch that the crane left running is in a position so that no harm would be done by overflow, supposing the waste pipe should freeze. Then, in case the supply pipe to cistern should freeze, felt round it would do good; for if the supply to boiler should cease for some days, then the boiler might dry up and get red-hot at bottom, in which state the water coming on suddenly might burst it. To prevent this, however, whenever the water does not run at hot-water crane the fire ought shortly after to be put out at the boiler. In putting in the expansion pipe of a hot-water boiler, it should always be put in with an incline down to the boiler, so that if the boiler was emptied no water would remain in said expansion pipe. This inclination of the hot pipe is for the purpose of facilitating the passage of the steam up it, which, of course, will help to keep it warm,—I am &c., PLUMBER.

Jan. 21.

ST. MARY-LE-WIGFORD, LINCOLN.

SIR,—I have lately seen a copy of the BUILDING NEWS for Friday, Dec. 30, 1870, which contains an article on the Church of S. Mary-le-Wigford, Lincoln. The writer expresses a fear that the tower of that church is about to undergo rough treatment during the proposed restoration, and as one chiefly concerned in that restoration, I beg to give him "authoritative assurance" that not one stone of the original fabric of the tower shall be touched, the only alterations which it is proposed to make in this part of the church being—1. the removal of the modern masonry which at present blocks up the Saxon arch opening into the nave; 2, the building up of the debased window which now disfigures the west front of the tower; and, 3, the removal of a hideous modern staircase giving access to the ringing-floor, which will in future be reached by a light movable iron ladder.

On two points the writer of this article has been misinformed. He says (1) "No particulars were furnished to competing architects;" and (2) "That it is proposed to add a new north aisle." On the contrary, a printed paper of instructions was forwarded to each architect who applied to me for information; and the proposed new aisle is not on the north but on the south side of the church.

One paragraph of the article, suggesting that the plans which have been chosen were selected simply on account of their cheapness, is a gross imputation to lay against gentlemen of high archæological attainments, of whom I have several on my committee. The plans were chosen unanimously before the estimates of expense were considered. The new south aisle and reseating of the whole church will raise the church accommodation from 270 to about 500 sittings, an allowance by no means too large for a parish which now contains over 2,000 souls. It will be an exact reproduction of the beautiful Early English north aisle, and the windows, doors, &c., in the present south wall will be carefully replaced in the south wall of the new aisle; the latter will, in fact, be merely the present south wall moved some distance further southward.

I will only add that my own wish was to have entrusted the work to J. L. Pearson, Esq., of Harley-street, London, but local circumstances induced me to forego my own inclination. But

one word more—the work shall be carried on in as conservative a manner as possible,—I am &c.,

GEORGE T. HARVEY,
Vicar of S. Mary-le-Wigford, Lincoln.

Lincoln, Jan. 16.

WESTMINSTER ABBEY.

SIR,—Has it been considered what an unsightly blot on the exterior of Westminster Abbey is presented by the restored pier of the most northerly flying buttress of the Chapter-house? Partly hidden from view, at present, by the boarding, it will be found a great eyesore when that temporary screen is removed, obscuring as it does the lights of St. Edmund's Chapel and obstructing the pathway to Poet's Corner. Given a flying buttress it will be argued that there must be a support; but that support need not rise above the spring of the arched buttress itself. If the buttress itself must stand, at any rate the roofing or companile tower of the pier might be dispensed with.—I am, &c., A. H.

January 21.

Intercommunication.

QUESTIONS.

[2109] WATER AND LEAD.—Can any of your numerous readers explain the following:—In the cisterns of a house recently erected, and which are lined with the best milled sheet lead, there have appeared several whitish spots on the lead, some on the bottom and others on the sides and standing waste pipes. On these spots being touched with the nail, the lead is found to be quite corroded and comes away in a fine powder, so much so that in a short time the lead will be quite eaten through. Now is this the fault of the water or of the lead? The water is certainly hard, but if the water is the cause why does it confine its action on the lead to spots, and not act equally over the whole surface of the lead with which it comes in contact. Is it possible to adulterate the lead so that the water would act so on the inferior parts of it? I shall be glad if any of your readers can enlighten me on this matter.—INEXPERIENCED.

[2110] LOAD FOR MEMEL TIMBER JOIST.—Will any of your correspondents inform me what would be a fair load for a memel timber joist to carry 12in. deep, 4in thick, and 17ft. between bearings loaded equally the whole length?—CARPENTER.

[2111] CONE OF RAYS.—Will some of your readers kindly give a little information on the following? I am studying Burchett's "Linear Perspective" for the coming examination of the Science and Art Department, but do not know how to determine the diameter of the base of the cone of rays; I should be much obliged if some one would tell me, as upon that point every other depends. Is the base of the cone of rays given in the examination papers? What kind of subjects are required to be delineated? and can I obtain a specimen of subjects given on former occasions?—STUDENT.

REPLIES.

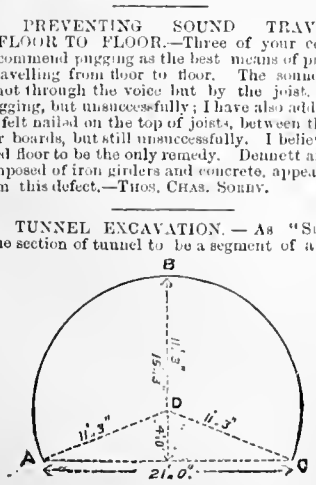
[2008.]—SEVENTEENTH AND EIGHTEENTH CENTURY ARCHITECTURE.—My reply to this query should have read as follows:—"Richardson's Old English Mansions."—F. E. M.

[2078] FENCING LAND.—The County Court judge was perfectly right. As a general rule each owner must take care that his own cattle do not trespass on his neighbour's land. Boyle *v.* Tomlin, 6 Barn. & Cres.—Z. Y

[2087] ASPHALTE IN CHEAPSIDE.—I am sorry to have to correct "P. E. M.," who has so kindly replied to many unanswered queries; the asphalte was not "heated and applied," but laid on in powdered state and then melted by means of rammers with iron heads heated in a portable furnace close to the scene of operations, only thin layers of the material being applied. This means of application being so different to that generally in use for other kinds of asphalte has induced me to trespass on your space. The same asphalte laid by same means is also in use in Holborn.—J. C. C.

[2095] PREVENTING SOUND TRAVELLING FROM FLOOR TO FLOOR.—Three of your correspondents recommend pugging as the best means of preventing sound travelling from floor to floor. The sound is conducted not through the voice but by the joist. I have tried pugging, but unsuccessfully; I have also added strips of thick felt nailed on the top of joists, between them and the floor boards, but still unsuccessfully. I believe an oak or framed floor to be the only remedy. Dennett arching, a floor composed of iron girders and concrete, appears to be free from this defect.—THOS. CHAS. SORBY.

[2097] TUNNEL EXCAVATION.—As "Surveyor" states the section of tunnel to be a segment of a circle, I



think the accompanying horseshoe arch must be the correct outline, the area of which (working to the dimensions given) would be about 286·16ft., being the sum of the area of the sector ABCD, and the triangle ADC. Rule to find area of any sector:—As 360° is to the number of degrees in the arc of given sector, so is the area of the whole circle to area of sector. The area of the triangle is so simply found that it would be superfluous to give a rule here. Whenever engaged on earthworks I have always measured to the full extent of excavations.—T. RASHLEY.

[2098] SPEAKING TUBES.—In reply to "H. H," I put a speaking tube from a large hotel to the stables (about 200 yards). I used the common 4in. rain water full pipe under and across the street, made the joints tight with putty; I also put a ½in. lead pipe through it, soldered a whistle on at the stable end, at the other end I fixed a pair of common household bellows. It has now been in use since 1850, and has had nothing done to it but a new pair of bellows, the others being worn out; of course the speaking is through the 4in. pipe.—C. S. S.

[2099] REMOUNTING PHOTOGRAPHS.—It will be found easier and preferable in all respects so rise "face mounts," (viz., thick cardboard cut with a bevel edge to outline of the photograph, the edge gilded or not, in accordance with taste) placed over the present mounts, and covering about 1-16in. of the edge of the photograph; by this means you hide the soiled margins without running risk of injuring the photographs by removal and remounting, and can at any time easily replace the face mounts when soiled, and at the same improve the appearance. Photographs mounted on boards only always have a poor appearance, which is obviated by the means herein proposed.—J. C. C.

[2100] TAYLOR'S PATENT TILING.—This tiling, if laid properly, is capable of keeping out the wet, and should be laid by the company's own men.—L.

[2100] TAYLOR'S PATENT TILING.—I have used Taylor's patent tiles on seven or eight occasions, and in one case at Sheffield, where the tiles were laid by the company, have seen them blow off by the score in a high wind, the fallen debris choking up the gutters and breaking other tiles in their descent. In another case at Brighton, also laid by the company, the wet frequently comes through. I have found them most dangerous things to walk over for any inspection or repair of roofs, &c.—T. C. S.

[2102] PIPES AND SMOKE FLUES.—I have tried terra cotta smoke flues and combined smoke and air flues of the same material, but find them too difficult to fix to be of any service. Few chimneys are straight enough to allow of their use, and to get them into the curves of the chimneys it is necessary to have them cut at the joints, which is a troublesome and expensive process. In the case of the combined smoke and air flues there is considerable difficulty in making a joint sound enough to prevent the smoke passing in to the air flue. Perhaps Messrs. Doulton or other makers may be able to give some information.—X. M.

[2104] TEMPERATURE OF DAIRIES.—It is absolutely necessary that means should exist in all dairies for preserving an equal temperature throughout the year; the cold of winter being hardly less injurious than the heat of summer. Care should also be taken to secure a plentiful supply of pure water, effective drainage by which the water may be carried rapidly away—thorough ventilation, and facilities for the exercise of the most fastidious cleanliness. The building should, if possible, be built on the side of a gentle declivity facing the west, and sheltered from the north and east winds. In order to maintain an equal temperature the walls should be of a considerable thickness and built with a hollow space in them through which a current of air may pass; the roof should also be of brick, of a curved or pavillion form, and the walls and roof may be plastered. The floor should be sunk about 3ft. under ground, made to slope to a drain (with bell trap) in the centre, and paved with tiles or polished stone. On three sides of the dairy small arches should be turned about 3ft. high, carrying a shelf of slate or marble 3ft. wide, to hold the pans containing milk, and a little above this shelf ventilating bricks should be placed with shutters sliding over them to open or shut, according to the weather. Several landed proprietors in this county (Shropshire) and in Cheshire, have recently erected expensive and highly ornamental dairies on their estates, fitted up with massive marble tables and milk coolers, and with a constant stream of water passing through them, but these are kept more as a luxury than an object of profit, and they seldom unite all the conveniences essential to a good dairy, because the architects who plan them are seldom or never practical farmers. I shall be happy to give "W. W." any further information on the subject.—A FARMER.

[2105] HEATING ENTRANCE HALLS.—I have used Pierce's pyro-pneumatic stoves with copious supply of fresh air, and found them answer well for heating hall. The stoves are now made by Mr. Penfold, and might be bought from either of the firms referred to. I have also used a stove manufactured by Steward and Smith, with the best results.—T. C. SORBY.

DEWSBURY.—A new Congregational church has this week been opened at Dewsbury. The whole of the front and the wings are constructed of tooled ashlar, from the neighbourhood of Huddersfield, and the remaining external portions of the building are faced with pitched Elland Edge wallstones, with the dressings of Huddersfield stone. The church windows are continued in one length through the gallery. The cost of the entire building, including fittings &c., is about £8,000. Messrs. John Kirk and Sons, of Huddersfield and Dewsbury, are the architects.

WATER SUPPLY AND SANITARY MATTERS.

IRRIGATED MEADOWS.—New irrigation works are being carried out on the Craigmillar property near Edinburgh, in accordance with plans prepared by Messrs. Stewart & Menzies, architects, Hill-street. It is proposed in the meantime to irrigate forty acres to the east of Cameron Toll, but if the experiment should turn out to be a successful one, arrangements will probably be made to take in a greater extent of land. The works now being carried out consist of the usual irrigating feeders and sluices. The inlet sluice for the irrigating feeders commences at the Powburn, near Cameron Toll, and the Powburn is diverted from its present course into the Braidburn at the point where it enters the Prestonfield property.

RAINFALL AND EVAPORATION.—On Monday last a paper was read at Edinburgh before the Royal Society of Arts, by Mr. Alex. Leslie, C.E., on "Rainfall and Evaporation in Relation to Water Supply." The paper was divided into two parts, the first of which related to the loss sustained by evaporation and absorption in various dirtricts, both in England and Scotland. Details were given of a numerous set of observations, from which it was seen that the loss varies in general from 12in. to 15in. annually, but exceptional years give different results. The second part had for its subject the greatest floods found to flow off certain areas, measured in tens of cubic feet per minute. This was found to be different in various places, depending on the configuration of the country through which the flood passed, and with a similar rainfall the amount run off differs very considerably. It was found to vary from 2 or 3 to as high as 30 cubic feet per minute. The chairman said the society were indebted to Mr. Leslie for the important facts he had brought before them. He held the opinion that the majority of the rain gauges were too small, and that they were not placed at a uniform height, but he left that matter to the Meteorological Society.

LAND AND BUILDING SOCIETIES.

NEWCASTLE BENEFIT BUILDING SOCIETY.—The 20th annual report and balance sheet of this society have just been issued. During the year 876 shares have been entered 21 realised, 26½ redeemed, and 45½ withdrawn, leaving at the present time on the register, including entrances the last subscription night, 873½ shares. The accounts have undergone a thorough audit, and the mortgage securities have been carefully examined by the auditor and committee appointed for that purpose. The profits made during the year will be allotted immediately after the annual meeting, by way of bonus, to all shareholders whose shares have been entered not less than one year, in accordance with the altered rule.

Our Office Table.

THE BOMBARDMENT AND THE PUBLIC WORKS OF PARIS.—The public edifices of Paris more or less damaged by projectiles are the churches of S. Sulpice, S. Etienne-du-Mont, and the Pantheon; the Polytechnic and Normal Schools; the Lyceums of Corneille, St. Leonard, and Descartes; the Ecole de Droit, Ecole de Medecine, and Ecole des Mines; the Sorbonne, the Observatory, the Gobelins; the Museums of Cluny, of Natural History, and of Mineralogy; the hothouses of the Jardin des Plantes, containing a magnificent collection of orchids, which are completely destroyed; the hospitals of the Val de Grace, La Pitié, La Charité, Les Enfants Malades, La Salpètrière, Les Jeunes Aveugles, Enfant Jesus, La Maternité, and Lourcine; and the ambulances of S. Perine, Dames Augustines, and the Jardin des Plantes are also damaged.

THE SURVEYORSHIP OF BRIDEWELL AND BETHLEHEM HOSPITALS.—This appointment is apparently much coveted by the profession, although it is not easy to say why it should be so in the face of the requirements of the Governors and the scanty remuneration offered. Upwards of seventy candidates sent in their applications at the time appointed. From this number thirteen were first selected, and on Monday last the number was reduced to five, from among whom the successful candidate will be appointed on Monday next. The names of the five gentlemen selected by the Governors are—Mr. J. T. Christopher, Mr. Jas. Edmeston, Mr. Frederick Marrable, Mr. F. W. Porter, Mr. Richard Roberts. We can only repeat with regard to this matter the opinion we have before expressed, that the eagerness exhibited by architects in the pursuit of these appointments and their indifference to the imposition of humiliating conditions is not calculated to raise the profession in the estimation of the public generally.

LIGHTHOUSE WORKS AT THE CHICKENS ROCKS.—The arduous and difficult work of erecting a lighthouse on the Chickens Rocks, off the Calf of Man, in which the Commissioners of Northern Lighthouses are engaged, has so far progressed satisfactorily. The work at the Chickens—a dangerous tide-covered rock which lies about a mile off the southern point of the Isle of Man, in the very hottest part of a rapid tideway—has been in progress for two years. It is under

the charge of the Commissioners of Northern Lighthouses, and designed by the engineers. Last season afforded 84 days on which landings could be made; but as the rock is covered at an early period of the tide, the time available for work has sometimes not exceeded an hour. The tower is built of granite from Dalbeattie, the stones being dressed at Port St. Mary, in the Isle of Man. Its outline is a hyperbola, and the masonry has been raised to the height of 13ft. The light will be revolving, and will be elevated 115ft. above high water.

INSTITUTION OF SURVEYORS.—At the ordinary general meeting, held on Monday, January 16th, the following names were read and passed for ballot, viz.:—As Members,—Richard Albert Notley, 27, Royal Exchange; Perry St. Quintin, 27, Royal Exchange. As Associates,—Edward E. James Castle, 4, Brick-court, Temple; Arundel Rogers, 2, Paper-buildings, Temple; Hugh Shield, 3, King's Bench-walk, Temple; Julian Horn Tolmè, 1, Victoria-street, Westminster; Frederick Meadows White, 4, Paper-buildings, Temple. The following candidates were balloted for and declared duly elected:—Thomas Fenwick Hedley, Sunderland; Alfred Owthwaite Sedgwick, Watford, Herts.

MEETINGS FOR THE ENSUING WEEK

MONDAY.—*Institution of Surveyors.*—"On the Land Purchases of the Tunbridge and Dartford Railways." By Mr. Edward Ryde. 8 p.m.

TUESDAY.—*Institution of Civil Engineers.*—Discussion on Mr. Bridges Adams' paper "On Train Resistance on Railways." 6 p.m.

FRIDAY.—*Civil and Mechanical Engineers' Society.*—"On Limes and Cements." By Messrs. R. M. Bancroft & H. E. Hunt. 7.30 p.m.

SATURDAY.—*Associated Arts' Institute.*—"On Traditional Ornament in Goldsmiths'-work" By R. H. Soden Smith, M.A., F.S.A. 8 p.m.

Chips.

Mr. W. E. Frost has been elected a Royal Academician in the place of Mr. McDowell, honorary retired member (since deceased). Three new associates have been elected.

The trees between the Albert Memorial in Hyde Park and the Kensington-road are being transplanted.

The Civil Service Commissioners are advertising for candidates for two technical clerkships; we presume they want architectural draughtsmen. The salaries are £150 per annum, rising £10 yearly to £300; and £100 rising to £200. The clerkships are to be the subject of an open competition, with an entrance fee of 10s.

On Monday last the Council of the Royal Academy examined the drawings submitted by candidates for the probationership. We are informed that the architectural drawings were very numerous, and that more than the average number of candidates were successful. This is evidently due to the alteration in the rules and the appointment of an instructor. The probationers' drawings for full studentship appear not to have been up to the mark.

The private view of the Watercolour Exhibition at the Dudley Gallery takes place to morrow, and the exhibition will open to the public on Monday.

The fine collection of pictures which belonged to Munro, of Urvan, and are now in the possession of his sister, Mrs. Butler Johnstone, is about to be exhibited in the South Kensington Museum.

We are able to announce that the lecture which Professor Tyndall has been kind enough to promise to the students of the Royal Academy will be on "Light." It will be delivered in March.

The building for the Exhibition of 1871 is now quite completed, and the reception of goods will commence on Wednesday next.

The art workmanship competition of the Society of Arts has this year, we learn, been fairly well responded to. The judges met to award the prizes on Tuesday last. Some specimens of iron-work and marquetry are spoken of as "specially good." Several manufacturers competed under the new regulations, by which the names of the workmen are appended to the objects exhibited.

The restoration of the north side of the choir of Lincoln Cathedral is now resumed, and the ceiling of the north-west transept repaired. The gallery over the north aisle has been removed.

The iron railings and brick wall at the bottom of Norfork-street, Strand, have been removed, and the thoroughfare thus opened to the Thames Embankment is directly opposite to the Temple station of the Metropolitan District Railway.

The death is announced of Sir George Hayter, principal painter in ordinary to Her Majesty, at the age of 78.

Mr. Clement Dunscombe, late assistant engineer to Mr. Baldwin Latham, has been elected, out of 102 candidates, to fill the post of Surveyor to the Borough of Kingston-on-Thames, vacant by the resignation of Mr. Slagg.

Timber Trade Review.

PRICES, 24th January, Per Petg. std. hnnd.:—Quebec 1st quality bright yellow, 12ft. 3 × 11in., 19*l* to 19*l* 5*s*; do. 2nd quality floated, 12ft. 3 × 11in., 12*l* to 12*l* 10*s*; do. 2nd quality dry floated, 12ft. 3 × 11in., 12*l* 10*s*; do. 3rd quality floated, 12ft. 3 × 11in., 9*l*; do. 3rd quality dry floated, 12ft. 3 × 11in., 9*l* 10*s*; Petersburg 1st yellow, 11*l* 10*s* to 13*l*; do. superior quality, 12*l* 10*s* to 14*l*; Dram 2nd yellow, 8*l* 5*s*; do. 3rd yellow, 6*l* to 7*l* 10*s*; Bollsta mixed yellow, 8*l* 15*s* to 10*l* 10*s*; Christiana 1st yellow, 7*l* 10*s*; Gothenburg mixed white, 9*l*; do. 3rd yellow, 8*l*; Gefle mixed yellow, 9*l* to 10*l*; do. 3rd yellow, 7*l* 15*s* to 8*l* 15*s*; Hudikswall 2nd yellow, 9*l* 15*s*; do. 3rd yellow, 7*l* 10*s* to 8*l* 15*s* Munksund 1st yellow, 9*l* 10*s* to 9*l* 15*s*; Norkoping mixed yellow, 7*l* 15*s* to 9*l* 15*s*; Sundswall mixed yellow, 9*l* 5*s* to 9*l* 15*s*; do. 3rd yellow, 7*l* 10*s* to 7*l* 15*s*; do. 4th yellow, 7*l* to 7*l* 5*s*; do. 3rd white, 6*l* 15*s* to 7*l*; do. 4th white, 6*l* 5*s*; Sandviken 3rd yellow, 8*l* to 8*l* 10*s*; do. 4th yellow, 7*l* to 7*l* 15*s*; do. mixed yellow, 8*l* 10*s* to 8*l* 15*s*.

Davis, Greets Green, brickmakers.—Standing & Littler, Garston, near Liverpool, paviours.—T. G. & J. T. Ladyman, Rochdale, builders.

THE BUILDING NEWS.

LONDON, FRIDAY, FEBRUARY 3, 1871.

THE FAMILY COACH.

WHETHER or no the application of the whip behind, so gently administered by one of the most venerable and venerated drivers of the professional "Family Coach," referred to in the pages of a contemporary, will for long or at all deter "aspiring" *gamins* from audacious attempts to accelerate the pace of the vehicle in question, is open to considerable doubt. For our part, while we cannot help smiling somewhat at the irate demeanour of the offended official, and at the rather amusing combination of the paternal with the magisterial element in the rebukes he has administered from his lofty position on the box-seat, we are inclined to consider as far more ridiculous in their way the fussy overtures of contradictory and absurd advice which are shouted out on all sides of him and his colleagues, not only by the *gamins* aforesaid, but by bystanders in general. In fact, the drivers, guards, and proprietors of this Family Coach are just now pestered out of their lives by a noisy troop, some of whom, clambering up behind, are content all the time to be carried along by it, and to add their own weight to the burden; and others who, taking no part in its proceedings and stuck' hopelessly in the mud themselves, yet shriek out so persistently about everything the coachmen do or leave undone, that it is no wonder the nerves of the latter should be disturbed. And what would these malcontents, if any purpose can be gleaned amidst all this contradictory clamour? "Leave the old hackneyed, beaten road," say some, "and go straight as the crow flies, and thus save some miles of distance." "But we can't go across ploughed fields, and should stick in the hedges and ditches if we did, remonstrate the coachmen." "Harness double the number of horses to the old rattle-trap, and so get along quicker, do!" shout others. "But we have got no more horses, nor money to buy any with," is the mild and not unreasonable reply. "Then try steam as the motive power, and so keep pace with the spirit of progress of the age," cries another "aspiring Gambetta" of the craft. "Yes, and sit on the safety-valve, perhaps, and get blown up sky-high for our pains!" is the final and authoritative, though perhaps hardly logical and consequent, rejoinder of the irate driver, who has been stung beyond all endurance.

To drop metaphor, however, there is a good deal deserving consideration in the retort made in defence of the Institute by its Secretary, Mr. Donaldson, to his "aspiring" friend, Mr. Phené Spiers, that "all the Associations formed for the improvement of the rising classes have in vain been tried and failed, and become bankrupt in funds and efficiency." Perhaps the assertion is rather too sweeping, and certainly the Architectural Association might well be excepted from such a category, since it is to all appearance more flourishing than ever. But then it must be remembered that that body wisely and modestly confines its action to efforts of self-improvement; and further, that its very existence precludes the Institute from obtaining any considerable number of students. The Architectural Exhibition has just died a natural death. The Architectural Museum is quaking for its existence, and the Art Classes are painfully struggling into the light. The Academy has just appointed Mr. Spiers himself a teacher of Architectural Art. Professors Lewis and Kerr hold forth at the University College and King's College respectively, and how much attention do the clamorous malcontents pay to the undeniable advantages which these several institutions have for long held, or are now holding out to the profession? Why, the Architectural Exhibition rooms used to appear like a melancholy desert. The magnificent library of the Institute is hardly ever visited. The echoes of the empty Architectural Museum answer, Where, where are the students to study the precious treasures collected here at such infinite cost and trouble? The Committee of the Art Classes are in despair at the falling-off already of the few students who were at first enrolled in their lists. The Professors alluded to are not yet overburdened with hearers, and Mr. Spiers is able to speak for himself as to how many such he has been able to collect. The aggregate will be found to be pitiable, and yet the Family Coach is, forsooth, at fault because it will not add to the competition for these apocryphal, sadly-neglected architectural students. For our part, we think the authorities of the Institute are quite right in refusing to go forth piping in the market-place to suit such obdurate children, who have no intention of listening to the voice of any charmer.

The Institute has already conceded so far as to have set up, in obedience to previous clamours, a magnificent steam engine to crack a few halfpennyworth of nuts, in the shape of the Voluntary Architectural Examinations, and these have but proved hitherto a *fiasco* not for want of energy on the part of the examiners and moderators, but for lack of the material to be examined. Look at the result of last year, and see what a mouse the mountain brought forth after all the labour, the pains of which were trumpeted to the world. For any good produced the Institute might as well have thrown the £100 this machinery cost them on that occasion into the Thames.

Another equally absurd outcry is that for a diploma; and the Institute is, in our opinion, quite right in turning a deaf ear to it. A diploma, such as is sought for, is about as likely to be obtained as a slice out of the moon; and if it could be obtained, what would be its use, and who wants it? Depend upon it it is only the incompetent who demand it. We have little sympathy with that highly respectable but mediocre majority of the profession who ask for such protection. Those who know the ground they stand upon are in no wise afraid of free trade. No family coach can drag a load of incapables up the hill of fame, and no royal or special road can be made for its ponderous wheels. It is not the machine that is in fault, nor even the driver. Let those who think it is that of the latter try their own hand at the reins. There is one merit at least in the concern—namely, that all its numerous proprietors have an equal voice in the direction of its affairs, and none are prevented from giving their opinions within it; and as to the grumblers outside, they can join its ranks themselves with the same aid, and try what their energy can do for the general good. If they refuse to do this, we can only advise the driver of the family coach to pay no heed to their clamour, lest, like the old man with the donkey, they at last have to carry it themselves.

SOCIETY OF ARTS.—ART-WORKMANSHIP, 1870-71.

IN issuing their instructions to competitors for the present series of prizes, the Council of the Society of Arts this year made a very important change. We read that, "having in view the International Exhibitions about to take place under the Royal Commissioners for the Exhibition of 1851," they have thought "it well to suspend for a time the form hitherto adopted in offering prizes for art-workmanship," and "have decided upon giving a series of rewards for special excellence on the part of all concurring in the satisfactory production of works of industry of the highest character. They consider that they can most effectually ensure their object by offering to manufacturers the highest distinctions they have it in their power to confer, and to workmen liberal money premiums." It will be remembered that it has previously been customary to select certain specimens of art-manufacture, which were photographed or cast, and placed before the workman for imitation or reproduction, giving him, however, the opportunity of choosing his own models or examples if he preferred so doing. We pointed out last year that the specimens exhibited under these latter conditions were the least satisfactory, because the workman produces much better results when he has some good model before him than he does when he is forced to rely upon his own taste and judgment in the selection of his copy. In our notice of the Workmen's International Exhibition at the Agricultural Hall, we had again to dwell upon this fact, and to show how frequently the skilled workman was led into gross errors simply from the want of a more discriminating taste.

The objects which have been forwarded in compliance with the new regulations are certainly less numerous than on former occasions, clearly showing that having to work from prescribed examples did not deter men from competing, as has been more than once authoritatively stated. Indeed, had it not been for the zeal with which Messrs. Cox and Son have come forward as manufacturers, the exhibition would have seemed an unusually small one. The part of the programme, moreover, which applies to manufacturers and to objects involving combined labour, has practically failed to produce the intended results, and we regret that it will therefore be scarcely possible for the Society of Arts to carry out their proposal of sending the premiated works as a contribution on their part to the International Exhibition, "showing the results of recent efforts which have been made to improve art-workmanship in this country." We must own that we are surprised to find that so few have availed themselves of the very liberal offers of the Society. The Exhibition is by no means representative of some of our commonest art-manufactures. One would have thought that here, if anywhere, both masters and men would have been proud to make a good show, especially in view of the forthcoming International Exhibition.

The wood-carvings are not up to the mark: perhaps the best of them is the dead pheasant, by Mr. R. G. Tuddsbury (No. 10). The bird is hanging by one leg to a sprig of oak, with some well-carved corn and foliage in the back ground. The material being lime-wood, the carving of the feathers on the breast is excellent, and the relief of the whole is well expressed. No. 5, an oak mirror frame of Elizabethan design, by W. H. Holmes, is very well executed, and in good keeping with the style chosen. Mr. J. Osmond's oak panel (No. 3), adapted from an iold example, is good in execution, but too uniform in the relief of the foliage. The oak frame by Mr. Nichols, with a very naturalistic treatment of flowers (No. 4), is coarse in execution and heavy in design: the scale of the ornament should in all cases be adapted to the object to which it is applied. The figure carvings, with the exception of S. Peter (No. 6), and the figures round the pulpit, are very poor. The pulpit (No. 1) and the lectern (No. 2) we have, if we mistake not, already noticed among the objects at the Agricultural Hall. They are here exhibited by J. F. Wilson, joiner, W. C. Anderson and J. Wilcocks, carvers. The pulpit looks more like foreign than English work; the design is fairly good; but the general effect of the whole is not pleasing. One of the best objects in the Exhibition is the marqueterie table designed and exhibited by Thomas Jacob (No. 12). With him were associated in its production C. Rich, marqueterie cutter, C. Helfer, engraver, G. Brown, turner, J. Platt, carver, and G. Tappin, polisher. The table, made of amboyna wood, has a circular top on a square stem, with inlays of various-

GILDING

is an easy transition. Gilt metal may be considered as, in the main, subject to the same rules as gold; but the same delicacy of treatment and high finish are not demanded. The relief must always be strong enough to clear itself, unless it be assisted by the burnisher, of which a more free use may be made. Gilding on wood, or other similar material, may be made more or less effective by judgment in execution to a far greater extent than would at first sight appear. The judicious or injudicious disposition of the burnisher may make or mar the whole piece. Surfaces which are much cut up should never feel the burnisher, which should be confined to such parts as present evenly-rounded or flat surfaces. The burnished parts should always be so placed as to assist in expressing the design. Carved surfaces should be in dull gold, care being taken that the "preparation" does not smooth away all the spirit from the work. When only a portion of the object is gilt, and the remainder shows wood as its material, I prefer that the gilt parts should also exhibit the texture of the wood.

FLAT SURFACE DECORATION IN COLOUR.

The same rules which we have been applying to the treatment of ornament in the solid apply in a different way to the coloured treatment of various surfaces. Here, similarly, the eye must be judiciously led to forget the imperfections of the material where it is imperfect, or to follow its excellence if it be excellent. A rough or irregular surface of wall must, in the first place, be absolutely without gloss, and its decoration must then be so carried out as to lead away from the considerations of surface. Continuous straight lines or fine curves are to be shunned, nor is delicate finish desirable. A certain breadth of effect and execution must be maintained, and the forms of ornament selected must be such as not readily to betray the slight distortions caused by uneven surfaces, but to lead the eye to follow the intention of their own forms. On the other hand, where the wall presents a singularly fine and perfect surface, this may be done justice to and explained, firstly, by making the coloured ground carefully even in tone and texture. It may even be thought desirable to maintain a slight gloss, but this must not be excessive. Fine details and strong lines may be used to any extent required, and the finish need only be limited by the skill of the artist. In this, however, a distinction must be observed as to the execution of those parts which are mere ornament and those which partake rather of the nature of pictorial art. The former are intended to add to the general effect of the room or building, and should therefore be executed in such a manner as to explain themselves and answer their end when viewed as part of the whole. However finely executed, the lights must be sharply preserved, and not toned off too gradually to the shades. A certain crisp solidity of touch, with a precision of intention, are indispensable, though they need never become obtrusive. I cannot do better than point to the decorations of Pompeii for examples of the execution of decorative ornament on a fine surface. When, however, pictorial art is introduced, I am far from desiring to limit the finish or to dictate the style or method of execution. The artist will, of course, comply with the condition that the general tone of colour and force of effect be such as to harmonise with the rest and assist the general result. Having done this, it remains with him alone to decide whether his work shall be most admired at a distance of one yard or five yards. It occupies the position of a gem in a fine setting, and invites admiration on its own account as well as by adding to the value of the whole. Yet, even with this freedom, the painter who has never painted for any surrounding but a gilt frame will find that he has much to learn before he can satisfactorily ally himself to the architect.

STAINED GLASS.

We have been considering how far the treatment of coloured ornament may be varied to meet the necessities of the surface to which it is applied, the variation being rendered necessary by the way in which the light, falling on those surfaces, affects the appearance of the ornamentation, and *vice versa*. We have, however, in stained glass windows, coloured ornament applied under totally different conditions. In wall treatment we had to *explain the surface*; but here we have nothing to do with surface, of which the eye can take no knowledge, the light being transmitted. It can, however, take note of outline, form, and colour, therefore especial care must be taken in respect of these elements of beauty. The leading forms must not only in themselves be pleasing, but must be so clearly defined as to be distinguished, in spite of the flood of light which pours through, the rays of which spread and overlap each other. But it is in dealing with the question of colour that the treatment of stained glass is really put to the proof. We have not only to arrange our colours harmoniously, but to make the most of our beautiful material. It is in the jewel-like appearance and play of colour that the great charm of stained glass lies, and our study should be to enhance, as far as possible, this special beauty. If we observe carefully the most admirable works of the old artists in stained glass, we shall find that one important means to their success lay in the skilful use which they made of the irregularity of their material. *With colours obtained by transmitted light, those are richest which vary most in depth.* This is an axiom which workers in translucent material (be it glass or enamel, or what not) should never forget. It is their first condition of success. Such homely illustrations as a decanter of claret, or a spoonful of currant jelly on a white plate, will explain my meaning as well as any. If the wine were in a flat vessel of uniform depth, the colour would be there, but half its rich play and flashing glow would be gone, for it derives these from the varied diameter of the vessel. So with the jelly, the colour of which is displayed (as in enamel) by the light reflected from its ground, the plate. If spread in an even coating, the colour is still beautiful, but the rich palpitating effect is no longer there. In large surfaces of one colour, the masses should be made up of several pieces of varying depth. In small spaces the varied thickness of the glass itself must be depended on. And where, as in a border, the same colour is repeated to a considerable extent, so far from matching each piece to the other, the skilful artist will seek how to *vary* them with most effect. Many of our best glass artists are well aware of this, but until the workman himself appreciates and understands how thus to give value to his work by studying his material, advance will be slow. Still, in knowledge of their material, the English stained glass workers of to-day surpass all their foreign rivals. Whatever excellence of pictorial design the much-vaunted "Munich windows" may possess, they betray absolute ignorance of the treatment of material. They are mere transparencies, and but for their greater (almost unfortunate) permanency, might just as well be painted on oiled canvas as on glass, of which they exhibit not a single characteristic. (Applause).

CONCLUSION.

We have now glanced at several of those materials which are in most general use for the purposes of art, especially of such arts as are most closely allied to the architect. In thus rapidly surveying the leading peculiarities of each material, I have endeavoured to point out that, although much may be done in *design*, much also remains in the power of the artist or workman under whose hands the crude lifeless material is wrought into the living treasure. It lies with him, not only to do justice to the conception of his own art in his own brain, but, in so doing, to seek for all the assistance and all the power of expression which he may derive from the substance which he has selected from the rich gifts of his mother earth.

A discussion ensued in which Messrs. Potter, Phené Spiers, H. W. Lonsdale, Lewis F. Day, Stamms, and J. G. Crace, took part, and the thanks of the Association were tendered to Mr. Crace for his instructive paper.

THE OLD AND NEW GENERAL POST-OFFICE.

THE "old and experienced official in Her Majesty's Office of Works" has, in the additions to the old Post-office, and in the design for the new building now being erected opposite to it, given us an idea of the amount of respect paid to the existing works of *architects*, and also the art quality of the productions to be expected under the Ayrton administration of his department; we say *respect* for the works of architects, because it is pretty generally understood, outside the Office of Works, that this is due from an architect when he has to make additions to, or alterations in, the work of a predecessor, and when that predecessor happens to be a man of the architectural "calibre" of Sir Robert Smirke, we should have imagined that "an old and experienced official" would not have disregarded such a rule; as an illustration, he need have gone no further than Somerset House to have witnessed the attention paid by Sir James Pennethorne—consistent with the requirements of the new additions—to the work of Sir William Chambers, the result being highly creditable to Sir James, and at the same time in harmony with the old building. We, of course, are not comparing the two as regards magnitude, but this first work under the—we may say—new system should not pass by unnoticed.

Externally the new addition seems to be central with and set back from the portico of the old building, and is higher than the top of the pediment, and consists of an erection presenting to the front a plain face of *cement work* with sloped sides, coped with stone, forming the gable end—we may term it—of the addition, which has side lights and seemingly skylights below; the two sloped sides of the end do not even agree, and there is an entire absence of intention to make the new work harmonize with the old. The face work of *cement* is certainly inexcusable. As a roof to an isolated workshop the work would be passable, but here the result is a spoliation of the dignity of the building by no means creditable to the "experienced official." A good view of it may be obtained from the corner of Newgate-street and Aldersgate-street, and we recommend our readers to visit the spot and see with what care our important buildings are treated.

As regards the new building, judging from the design as published by a contemporary, it is beneath criticism. We challenge the most observant critic to point out throughout the design one particle of originality, excepting, perhaps, the absurd rustication of the central columns supporting those of the pediment above; the design of the central door, of which a detail is given, is disgraceful, and the whole, omitting the central feature, might, perhaps, pass for a row of second-class dwelling-houses; but as a design for an important public building, is an insult to the art architects of the period. W. W.

SOCIETY FOR THE ENCOURAGEMENT OF THE FINE ARTS.

ON Thursday evening, 19th inst., the thirteenth session of this society was inaugurated by a *conversazione* at the Suffolk-street Gallery, Pall Mall, which was kindly lent for the occasion by the Council of the Society of British Artists. The Society for the Encouragement of the Fine Arts was founded in December, 1858. Its objects are indicated in its title. Through its agency, a point of agreeable re-union between the artist and the amateur has been established, where their mutual interests may be made known and cared for, and the principles which should regulate the arts in their important mission discussed and disseminated. The scheme of the Society, so far as it has been developed, includes exhibitions of works of art, when papers are read and discussions take place upon questions of art; lectures on all branches of the fine arts, when discussions are invited; and *conversazioni*, with performances of vocal and instrumental music. The opening *conversazione* was very numerously attended. In the course of the evening Dr. Heimemann, professor and lecturer at the Crystal Palace, delivered an address on the principles and objects of the Society, and a well-selected programme of vocal and instrumental music was gone through, under the direction of Mr. Alfred Gilbert, the hon. musical director of the Society. The choice specimens of art upon the walls of the various rooms comprising the gallery of the Society of British Artists were not the least attractive features of the evening's proceedings.

ART AND ITS BELONGINGS.

ART and its belongings, says Mr. Muckley, head master of the Manchester School of Art, require to be brought repeatedly before the notice of the English public, more than any other department of education, and if we are to succeed, it is necessary for assurances of its value to be insisted on continually by those who understand it best. The love of the beautiful in Art has yet to be recognised amongst us as one of the subtle and for the most part hidden instincts of our nature, and to those who can cultivate it from proper motives new and

continuing sources of delight and happiness it will bring as a reward.

With the earliest people of our species, Art instincts and a yearning beyond the bare wants of the flesh have always been manifested in a most extraordinary way, and the expressions of Art feeling which they have evinced in divers forms have been of a perfect kind, seldom erring either as to quantity, form, or colour; and just as the bird selects the never-varying materials to build its beautiful nest, with a knowledge of which we know nothing, just so was it with the earliest tribes of our race—the necessities of existence and the useful were certainly the first things for their consideration, and then the ornamental.

In his migratory movements, the rudest appliances to propel the canoe of the savage were first invented, and as soon as this condition was met, he carved a thousand beautiful devices on his boat oar. In search for food in the chase, he handsomely decorated his weapons, and the handle of his hunting knife was ornamented in a perfect manner and according to the highest instinctive expression of his natmre, but not until he had killed and eaten.

And so it is, I am willing to believe, with regard to our own position in the present era; the necessity for the useful up to a very recent period has been the all-absorbing theme, and that we do not as a nation repudiate the real and living worth of the beautiful I am convinced, but on the contrary, I feel certain the time has now come when this country, individnally, will desire a full development of the higher instincts of our being. The manifold form of its seekings may perhaps be vague, and to many appear unmeaning; nevertheless, I do feel it is in your power, and in the power of a few others in this city, to lead forward the cause of Art, to raise the standard of its appreciation as connected with the various branches of industry under our control, and the familiar objects intended to be in and about our dwellings: in short, to weave the golden thread through the lives of those with whom we live, and for which their children's children will thank you.

THE FOUNDATIONS FOR THE NEW LAW COURTS.

The following tenders have been received for the foundations for the New Law Courts:—

Gammon & Sons	£68347
Holmes & Nichol	66900
Lucas Brothers	65719
Myers & Sons	57435
Lee & Sons	56500
Taylor Johnson & Smith	54240
Markwick & Thurgood	49000
Holland & Hannen	48300
Kirk	48182
Webster	47500
Cubitt & Co.	46555
Brass	46240
Trollope & Sons	45473
Perry	44973
Browne & Robinson	44680
Hill, Kiddel & Waldram	42750
Higgs	41987
Henshaw (too late)	38350
Axford & Whillier	37175
Dove Brothers	36755

Certainly tendering must be a game of chance. In fact, it looks as if it were as bad as betting. It will be seen by the above that there was only the trifling sum of about £32,000 difference in estimating for the foundations of the Law Courts.

Building Intelligence.

CHURCHES AND CHAPELS.

BOSCASTLE, CORNWALL.—Minster church has just been reopened, after a general restoration under Mr. St. Aubyn, architect, of London. The galleries have been removed, and low free seats have taken the place of the former high pews. The pulpit has been removed to another position, and the harmonium and singers placed in the chancel, which has been restored at the expense of the rector, while the general restoration of Minster church has been effected at the sole expense of the lady of the manor, Miss Hellyar, to whom also belongs the advowson and patronage of the livings of Forrabury and Minster. Mr. Burt, of Launceston, was the contractor.

EDINBURGH.—A new oak reredos has just been erected in St. John's, Princes'-street. The design consists of a centre portion above the altar, and two side pieces connecting the centre with the east pillars of the nave. The centre portion is about 8ft. in height above the super-altar, and 7ft. long, and is formed of three richly-traceried arches, each flanked with an elaborately moulded and panelled buttress, and finished on the top with a deeply carved and moulded cornice and open cresting. The buttresses are carried through the cornice, and terminate in gableted and crocketted pinnacles. The three panels within the three arches are at present covered temporarily with red cloth, corresponding with that of the altar below, but it is intended that they shall be filled in with an ornamental design of some kind, probably on a dead gold ground, and it is contemplated also to bring out the leading lines of the design by gilding, as was done so successfully with the traceried ceiling of the nave. The work, which has been entirely executed in solid American oak, has been carried out by Messrs. Davidson & Read, of Frederick-street, from the designs of Messrs. Peddie & Kinnear, architects.

FARRINGDON, DEVON.—The parish church has been entirely rebuilt from the designs of Mr. W. White, F.S.A., of Wimpole-street, London, and was consecrated by the Lord Bishop of the Diocese on the 14th inst. The parish is a small one, containing little over 300 inhabitants. The style of the building is transition from First to Second Pointed, and consists of chancel and chancel aisle, nave and north aisle in three bays, the easternmost bay being carried out transeptally, a south porch and western tower, with an oak shingle spire capable of receiving four bells, but at present there is only one. The spire is surmounted by a large vane. We believe there is only one other shingle spire in Devonshire, that at West Worlington. The walls are built of local stone, with Ham Hill dressings, and the interior is lined with brick. A good deal of the Beer stone of the old building has been used and mixed with the Killerton stone; it has a very good effect. The roof, which is an open deal one, is covered with plain tiles. Accommodation is provided for 150. Chairs are provided, and the floor underneath them is composed of wood blocks, on a principle of the architect's, and as adopted latterly by him at Lankey Church, near Barnstaple. In the passage up the centre of the nave, the old mural stones that were in the ancient buildiog have been again laid down, but they are lined with ornamental tiles. On the chancel floor Minton's tiles of considerable richness have been laid. The chancel is lighted by three stained glass windows, the gift of the Ellacombe family, which has long been connected with the parish, as the monuments on the walls testify. The east window is a three-light one, and represents the Nativity, Crucifixion, Resurrection, and Ascension. This window is the gift of General Ellacombe. The other two are small two-light ones, and are placed on the south side. Ward & Hughes of London supplied them. The choir stalls are of oak, as also is the pulpit, which is raised scarcely 18in. above the floor. The altar is formed of a panelled front, with detached shafts carrying a massive marble slab, over which is a marble cross. The old Norman font, which was very much dilapidated, has been carefully restored. It is Late Norman in character, and the restoration has been carried out in accordance with the fine example of a similar date existing in S. Mary's Steps Church, Exeter. It has a massive oak cover, which is new. There is a little stone carving upon the building, which, as the meritorious effort of an amateur, deserves a passing mention; it has been executed by the clerk of works, Mr. George Vickery, during his spare hours. Mr. Mayell, of London, was the builder, and the total cost of the work has been about £1,350. The farmers of the parish provided the cartage for drawing the materials free of expense.

HACKNESS.—S. Peter's Church, Hackness, near Scarboro' was re-opened on the 18th inst., after restoration by Mr. Ewan Christian. Under his direction the galleries have been taken down, all the plaster removed from the walls; the seats, which were narrow and inconvenient, replaced by handsome oak sittings, more conveniently arranged; the old vestry thrown into the church and a new vestry constructed. The ceilings have been removed and open roofs substituted, the roof of the chancel being of higher pitch than before. The wall of the south aisle, being very dilapidated, has been taken down and re-built. In the chancel, an old window which was blocked up has been opened out, and another old window has been restored, and all the windows have been re-glazed, some new ones being inserted in the north aisle. The contractors for the work were the Messrs. Pedbury, of Selby.

HULL.—On Saturday last the new Church of S. Silas, Hull, was consecrated. The building contains sitting accommodation for 660 persons, and consists of nave, with north and south aisles, chancel, organ chamber, and vestry, and is built in the Gothic style of the twelfth century, from the designs and under the superintendence of Mr. Samuel Musgrave, Hull. The church is constructed of bricks and faced with red stocks, with bands of blue Staffordshire bricks, tracery, and other dressings. Ham Hill stone has been used. The interior of the church has Bath stone columns, with moulded caps and bases, and parti-coloured brick arches and stone labels to the nave arcade. The chancel has an apsidal termination, and has moulded brick arch and stone sub-arch resting on bold moulded corbels and shafts of Bath stone, with carved capitals and moulded annulets and bases. The contractor for the whole of the works was Mr. Musgrave, of Hull.

LYNMOUTH, NORTH DEVON.—The new church of S. John the Baptist, now erecting from the designs of Mr. E. Dolby, of Abingdon, near Oxford, is nearly complete, and is expected very shortly to be available for use. The style is Early in character, and the building consists of nave with south aisle, apse, and organ chamber, with porch at north-west corner of nave. There is a bell-turret for two bells on the western gable. The edifice is built of limestone, and the same material is displayed on the inside as well as outside walls. The dressings of the exterior are of Ham Hill stone, and those of the interior of Bath, Ham Hill, and Forest of Dean stones. There is a stone groined roof to the apse, springing off moulded and carved corbels, the roofs of nave and aisle being of open timber. The windows, excepting those on the north of nave, are small lancet ones, with a very deep splay. An arcade of three bays divides the nave and aisle, the capitals of which are somewhat richly carved with conventional foliage. The whole of the floors are laid with Maw's tiles. The stalls are of oak, as also is the altar-table, which latter is raised by a series of steps to some altitude above the level of the nave. The rest of the church is to be seated with chairs, excepting only in the part used by the school children, for whom deal benches are provided. The whole of the work is being executed by Messrs. Oliver and Son, of Barnstaple, at a cost of about £2,000. The carving is by Hems, of Exeter. Mr. Lewis officiated as clerk of works during the earlier part of the work, but latterly the services of a clerk of works have been dispensed with.

WILLESDEN.—Two handsome memorials have lately been erected in the parish church of S. Mary, Willesden, which greatly improve the chancel. The one is a reredos of Caen stone and various coloured marbles, with light open tracery showing the east window at the back, with the words, "Holy, holy, holy, Lord God of Hosts," in gold letters on a blue ground beneath the window. The other is a very rich encaustic and mosaic pavement for the sacrarium. Both memorials are from the designs of Mr. Tarver, architect, and are given by the Mason family and Mrs. Metcalfe respectively.

THE HORSE SHOE CLOISTERS, WINDSOR CASTLE,—The restoration of this ancient pile of buildings at the west end of S. George's Chapel, Windsor Castle, is progressing rapidly. The herring-bone brickwork of the houses, divided into panels by oak beams, will, when finished, present a picturesque contrast to the rest of the Castle architecture. The architect is Mr. G. G. Scott.

PRESERVING WOOD FROM DECAY.—By the process of Mr. Archibald B. Tripler, of New Orleans, wood is said to be preserved from decay in the following manner:—The wood is cut into two or more equal parts or slabs. These pieces are bored at equal distances to receive the trenails to unite them, and they are immersed in a solution of coal-tar and powdered charcoal, either hot or cold, in equal or unequal parts, which not only thoroughly impregnates the slabs with carbon, but coats the surface with an adhesive material, so that when put together their adjacent sides will adhere together, and form interior partitions or walls of antiseptic or preservative agents, extending from one end of each slab to the other. These slabs are then united with trenails, or double pins, in such a manner as to lock them as firmly and solidly as if they were one piece. The timber thus prepared is immersed in a solution consisting of asphaltum, or mineral pitch, 80 parts; sulphur, 5 parts; arsenic, 5 parts; coal-tar, 5 parts; powdered charcoal, 5 parts;—in all, 100 parts. This solution will cover the surface, and fill up the joints and crevices between the slabs, rendering them impervious to water, and effectually preventing atmospheric decomposition by insulating it from the decaying influences of the elements.

EXHIBITION OF THE WORKS OF OLD MASTERS AT THE ROYAL ACADEMY.

Another Notice.

OUT of evil comes good. When the British Institution collapsed through the inertness of its old members, and the interesting exhibitions of ancient masters that used to take place in Pall Mall, had to be discontinued, it seemed very doubtful whether any such display of the works of the great painters of past times would again be given. The thanks of all Englishmen are due to the Royal Academy for the spirited way in which the matter has been taken up by it. It was thought that the admirable collection of last year, as being the first, and so got together with extraordinary zeal and pains, was little likely to be rivalled in future years. To some extent the former collection did stand by itself, especially in some of the larger works—but still the present exhibition is a splendid sequel to its predecessor. In some respects it surpasses it, especially in the Early Italian and the Spanish schools. In one respect the large collection, numbering 426 pictures, is less instructive than some of the smaller ones in Pall Mall, inasmuch as there is not the same opportunity of comparing the various specimens of the same master and different masters of the same schools. A little more classification would have been advantageous. But with so fine an assemblage of the choicest paintings in our sight, we must not be too critical about the details of the exhibition. The first feeling upon going through the rooms was one of bewilderment at the variety. It was some time before one could settle down to study the collection, of the general quality of which there can be no question. It is admirable. There are, however, several paintings which should never have been admitted. Most notably the so-called Muller and Turner, neither of which have more than a colourable resemblance to the works of those masters. Of course some attributed to Raffaelle are not by him. There are so few originals of his in this country that it is as well to show the reputed ones, especially when, as in the present instance, undoubted examples of his beautiful works will show the intelligent observer why the copies or school pictures are not by him. The greatest contributors are Lord Ashburton, Mr. Wynne Ellis, the Earl of Warwick, the Earl of Dudley, Lord Overstone, Mr. Thos. Baring, and the Marquis of Westminster. But many who have sent fewer pictures have equalled, as far as quality is concerned, the largest and noblest contributors. Lady Eastlake, for instance, sends only three, but for every great quality they are surpassingly good. Mr. Louis Huth's "Old Chrome," is a host in itself; for facility, power, vigorous treatment, and truth to nature, it is scarcely to be excelled. The Marquis of Lansdowne sends only two, but then one is the portrait of Lawrence Sterne, by Sir Joshua Reynolds; Mr. G. C. Schwabe's beautiful pictures, by Dyce, are another instance of quality above quantity.

We will begin our detailed notice with the landscapes, of which there is a splendid show, both by our own and foreign artists. The Marquis of Westminster's landscape by Philip de Koning possesses all the excellences of that great but scarcely appreciated painter. We have little doubt that many so-called Rembrandts, especially those most highly finished, are really his work. In the present instance there is a grand expanse of country, with Cleves in the distance, done with the accuracy of a photograph, but entirely free from all hardness—the great distance is admirably portrayed. It is, in fact, a perfect bird's-eye view of the scene. With less breadth, but painted with equal success, are Jacob Ruysdael's "grand water mills," No. 56 belonging to Mr. Wynne Ellis, a work of very great merit—the tumbling out of the water as the sluices are opened is exactly true to nature; and 64 belonging to Mr. G. Field. But even these, in our opinion, are eclipsed by the Marquis of Westminster's extraordinarily fine example of Hobbema, No. 96, "A Forest Scene with Figures."

Of the English school we have already mentioned the grand Chromes 7, 35 and 45, all splendid examples. The oaks in No. 7 are beyond all praise. It seems only right that such a vigorous hand, of such unhesitating power, should have dashed off the prince of trees. There are several fine Constables, the finest being No. 16, "The Hay Wain," which was exhibited in Paris in 1825, and gained the gold medal. This is a truly magnificent picture, and admirably true to nature; the patient, inquiring dog, the quiet ducks, the noisy carters, the light through the trees in mid-distance, so skilfully thrown in, all bring the scene literally before the eyes. Somewhat less important, but equally true and capital, is the view of Flatford on the river Stour, lent by Miss Constable. By Calcott there are two specimens, both beautifully drawn, but ill coloured, chalky in tone, and quite unnatural. The sea-piece, 124, would be a remarkable bit of description if the water were only wet and of the right colour.

We must not close our remarks upon this part of the collection without noticing the grand Burghem landscape, the perfect keeping of which is so delightful. This is another of the great Westminster Collection. Seldom has any artist lived to paint such a landscape and such figures and cattle. Notice especially the admirable finish of the white cow. There is scarcely anything more charming in the whole collection. But of all marvellous things in the landscape way, surely nothing surpasses the peep through the windows of the exquisite John van Eyck's S. Jerome, called in the catalogue (191) "A Philosopher in his Study." If it was not too much almost to expect Royal Academicians to trouble themselves about pre-Raffaelite stuff, such a curious misnomer would be astonishing. This philosopher is the most perfectly correct S. Jerome that was ever painted. He is clad in red; his red cardinal's cap is at the side; his lion is rampant in the background; his favourite birds are running along the foreground; and the picture is one of the choicest things we have ever seen. It possesses every virtue of the highest possible finish, without any of its drawbacks. As we look at it we wonder how ever such a touch could have been attained. What superlative excellence of colours! 450 years have not changed them. The picture is as fresh as when it was elaborated. The landscapes through the openings in each side are simply astonishing. The amazing amount of detail, all in perfect perspective, without the slightest hardness, in the space of two or three inches! This picture throughout will repay the most minute attention and scrutiny. In minuteness it surpasses even the other examples of this glorious painter, fine as they are. Mr. Hope's very pure and carefully painted "Virgin and Child" is too well known to need much description, though at South Kensington it has never been possible to examine it as well as it can now be seen. Many who have often seen it before will be surprised at the extraordinary delicacy of the finish of the flesh, the glowing gems of the diadem — the exquisite chiselling of the sculpture. It may be interesting to note that the representations of the church and the synagogue are almost identical with the famous carvings on the door of Rochester Cathedral.

The third, and to some extent the most important, of the Van Eyck paintings is Lord Dudley's beautiful example, "The Celebration of High Mass." Though nothing can surpass in taste and finish the charming "S. Jerome" before mentioned, this excels it in variety of interesting detail, greatness of subject, and broader scope. Whether we consider the admirable harmony and splendour of colour, the exact representation of every most minute particular of the scene, or the composition and feeling of the figures, this is in every way a most extraordinary painting, and worth the most earnest study. It is particularly valuable architecturally, and for its ritual characteristics. As in Mr. Hope's picture, the sculpture is most beautiful. The carpets and coverlets are a study of themselves. One use of triforium galleries is indicated—viz., to enable the servants of the church to let down the costly hangings, which even now in some foreign countries form so striking a part in the festival decorations. Special attention is due to the gorgeous metal dossel, with its elaborate chasing and enamelling. The detail is so perfectly given as to enable any competent person fully to realise the work as it really existed. From these inestimable gems of art we will turn to the somewhat later Italian works, but before doing so we must not pass over the richly-coloured and finely-conceived "Last Supper," by Giotto. From the whole feeling of this picture one cannot fail to notice how much the English school of the fourteenth century was affected by the Italian, especially in the taste for colour. Foremost among the fifteenth-century works of Italy is the great triptych by Fra Angelico de Fiesole, which, notwithstanding the darkening of the colours generally, is a fine specimen of the master. It has been said that he could only paint angels, saints, and good people; but this picture, in our opinion, contradicts the common saying. Very few paintings of the same date show more power in description of evil passions and suffering than this. The tyrant with the snake diadem is marvellous; so are the envious ones, and the quarrelsome tearing each other's flesh. In some of the vicious groups a very fair knowledge of anatomy is shown. There is amazing power, considering the date, in the avaricious man held down by the hair of his head while the demons pour molten gold down his throat. Still, doubtless by far the most attractive part of the subject is the grand choir of Heaven, seated in its eternal serenity of peace, and the joyous circling hands of the Blessed dancing, as it were, through the clear blue ether; one, hardly believing that such blessedness could be hers, is directed by the angel to turn from the downward road of misery. How lovely is the ethereal buoyancy of the ascending saints as they fly through the air. When the picture was in its original lustre, the upper part, where the angels' wings are beautifully stamped and indented, must have sparkled like gems, as we sometimes see happens in the finest Italian miniatures of the same date, such as occurred in Mr. Ottley's sale, now in the choice collection of the Rev. T. Fuller Russell. Another very remarkable picture, though in every way inferior to this, is "The Nativity," ascribed, possibly with truth, to Botticelli, though if so he must have been considerably over seventy years of age. The circle] dance of angels is very similar to what we have just noticed, as is also the loving embrace of the angels. All the shepherds are crowned by angels with the evergreens, and peace to the men of goodwill is portrayed. The Devil, in dismay, and grinning horribly, is forced to retreat from the happy sight, while an angel choir is carolling on the roof of the inn. There are other works of this master. 294, one of his great circular pictures, is a capital example —very religious and monumental. None is equal in feeling to the choice specimen at South Kensington, belonging to Lord Elcho. Of pictures of this class scarcely anything approaches "The Wise Men's Offering," by Andrea Mantegna—an admirable production in the artist's best manner, though a good deal the worse for age. Few pictures so fully and beautifully tell their story. It is, in fact, of the very highest quality. The various expressions of reverence in the young Eastern, the negro, and the old king who is offering his gold, is most striking. The finish of this picture is equal to anything but the Van

Eycks in the whole collection. By Filippo Lippi we have a fine study for an adoring angel in tempera (No. 281). In the driest, but still a grand and impressive style, is Carlo Crevelli's great picture (303). The richness of the ornamental decoration, fruit, and flowers, and the splendour of the dresses, are remarkable; but there is an exaggeration of muscular development and expression which detracts much from the works of this artist. These faults are more especially to be noted in the Pieta (318). The collection cannot boast anything by Leonardo da Vinci equal to what was shown last year; still there is a good representation of "Christ bearing the Cross" (275), and two fine crayon drawings (268 and 270). By his imitator, Luini, there is only one questionable example (290), a replica of the figure of Christ in the picture (so terribly retouched) in the National Gallery of his disputing with the doctors, which is ascribed to Leonardo da Vinci. It is a pity that the paintings by this great man have been so frequently ascribed to Leonardo, possessing, as they do, most valuable qualities of their own, and certainly never needing any other name to recommend them. Of Leonardo's contemporaries, we have a first-rate work of Lorenzo de Credi's. It is astonishing that so great a painter should almost till our time have been disregarded, as merely a copyist of Leonardo's works—to which, in fact, in colour and execution, they really bear little resemblance. There are few finer instances of this distinguished artist than Lord Dudley's "Holy Family" (302). The colour is exquisitely pure—nothing can surpass the intensity of feeling thrown into the adoring, reverent face of the little S. John. The landscape in the background is excellent. Giovanni Bellini is splendidly represented in the present collection. It is difficult to imagine finer specimens than Nos. 92 and 315; the former the property of Lady Eastlake, the latter of the Earl of Dudley—an exquisite "Virgin and Child;" both mother and infant of wondrous beauty. No. 92 is more important in subject—"The Virgin and Child surrounded by Saints." He is blessing the donor of the picture. The chief interest of the whole is concentrated upon the divine infant. It is one of the most religious pictures we know. On either side of this, also belonging to Lady Eastlake, are good examples of single figures by Giovanni Baptista Cima. Of the same school Lord Dudley has a "Holy Family" (300), by Marco Basaiti, which is in all respects, though certainly authentic, very inferior to the picture by him in the National Gallery. This is partly due to its having been carelessly restored at some time or other. We now turn to the great master of Raffaelle. By Perugino we have five pictures, all of small size and importance, but interesting as showing whence his greater pupil derived his earlier training. By Raffaelle himself there are but three originals, one large "Crucifixion" (307), said to have been executed when he was only seventeen. It is entirely like Perugino, but inferior to his better work. As one might expect, it wants power; the angels with flying bands are very weak; the repose of the Saviour is good, but the best point is the S. Jerome. Very different in power and quality is the priceless little gem (309), "The Three Graces." As at Leeds, so here, this forces itself upon one's notice, and claims for itself the pre-eminent place, though in such princely company. We doubt if any picture of its size exercises so magic a fascination upon all beholders. 285, the Marquis of Westminster's "Holy Family," is only a school picture. There is but one Francia (319) a good example, and that is all. There is also only one Sasso Ferrato, a fair specimen, exhibiting all his faults and beauties. The hard contrast of colour is scarcely pleasing. Of the school of Venice there are many splendid things. There are ten by Titian. Excluding the portraits for the present; the two finest are the Marquis of Westminster's "Woman taken in Adultery" (63), a splendid composition, though hardly true to the Gospel narration, and Lord Dudley's (365) "Susanna and the Elders." The treatment of the subject is very curious, but the painting is excellent. The loveliness of the face reflected in the mirror is enchanting; the landscape in the background is capital. "The Golden Age" (334), by his fellow pupil, Giorgione, is a gorgeous piece of colouring—the feeling as deep as the tone of colour—all sunshine and happy peace.

Conspicuous for rich and harmonious colour are the pictures by Tintoretto, of which there are four; 95 is a sketch of a large picture at Venice; 151, the great one from Hampton Court, lent by her Majesty. Notwithstanding its merits in colour it has many faults—exaggerated mannerism, heavy unmeaning shadow with great indistinctness of outline. In every way better is Lord Dudley's "Christ Delivered to the Jews" (328). By Palma Vecchio and his pupil Bonifacio there are good examples, 329, 357, which may well be compared, the latter surpassing his master in taste, colour, and composition. His models are very fine. Of the later Italians we have good but uninteresting Carlo Dolces, 73, 81; a poor Domenichino, 167; and several Guidos—3, a very sweet "Sleeping Christ," the Virgin Mother adoring. The most important one is "S. John in the Desert," 276, lent by the Marquis of Westminster. We must conclude our notice of this part of the collection with Paolo Veronese. Of the four pictures by him by far the finest and most interesting is that lent by the trustees of Lord Taunton, a very lovely instance of the favourite subject, "The Holy Family with S. Catharine." The only fault is that the composition seems somewhat cramped. It is quite possible that the canvas may have been curtailed. It is seldom that so grand an assemblage of Italian art almost from the earliest time has been brought together.

DECORATIVE ART.

MR. E. J. POYNTER, A.R.A., delivered a lecture very recently at the Midland Institute, Birmingham, on "Decorative Art." He commenced by saying that the lecture would deal with the elements of beauty in decorative art; the first part being devoted to the subject of our art manufactures, and the second to painting. He announced that whatever was made by man was capable of being made either beautiful or ugly, in a more or less degree, and their productions might be divided into three broad classes: first, those objects which, being made simply for use, without after-thought of beauty, were not susceptible of decoration or were not fitted for it by reason of the rough usage to which they were exposed; second, that vast class of productions which, being also made for use, have been found capable of being ornamented, and whose beauty of appearance was considered of more or less importance; and, thirdly, those objects which were made purely for purposes of decoration and for the sake of their beauty. After enlarging upon the beauty of fitness and the beauty of workmanship and appropriate decoration, the lecturer said no work of art manufacture could have any pretensions to be called beautiful unless it had the first and second elements of beauty—fitness and workmanship; and, unless it had these two qualities, it could not, by any possibility, be rendered beautiful by the most elaborate and best executed ornament which could be applied to it. He attributed the decline of art in this and other countries to a dread of appearing to be able to afford handsome things, and, combined with that, especially in this country, a desire of rapidly making fortunes—the root of all that was sham and bad about us. Expensive shams took the place and commanded the name of beautiful work, and this was so much a part and parcel of the spirit of the age, that the people had really come to believe that progress meant this and nothing more. He pointed out in detail what the elements of beauty were which were necessary in a work of art manufacture, enforcing the fact that without good construction and good workmanship no work could have any value as a work of art. He next considered the question of decoration, treating of it first with regard to smaller objects, such as household furniture, plate, &c., and dealing with the larger matter of decorative painting in the second part of his lecture, illustrating the principles he laid down by references to the works of Michael Angelo.

SUITABLE LAND FOR SEWAGE PURPOSES.

IRRIGATION in some form or other is sure to be sooner or later the universally adopted method of disposing of our sewage, and it therefore becomes all interested in the matter to turn their attention not only to the best method of irrigating the land, but to the selection of land best suited for irrigation purposes. The latter part of the process has not to the present time received the attention it demands, and we therefore were glad to see the subject treated with his usual success by Mr. J. Bailey Denton in a paper recently read by him at Maidstone. The paper is throughout a valuable one, dealing exhaustively with the sewage question in all its details, and bestowing special attention on the point above alluded to. When irrigation was first proposed many seemed to suppose that sandy and waste lands were the proper places to receive the sewage. The old idea of its being, after all, somewhat of a nuisance, has not yet left us, and we were careless about its value so long as we could insure its final disposal without polluting our streams and rivers as of old. Mr. Bailey Denton's experiments, confirmed by the opinion of Dr. Voelcker, the well-known agricultural chemist, point to clay lands as the most advantageous for the distribution thereon of sewage. If properly drained and subsoiled, the water percolates through them as easily as through a sandy soil, and, generally speaking, the crops raised from such land will be of a superior quality. Sandy and gravelly lands not only require more sewage than clay soils to insure a productive growth, but they frequently allow the sewage to pass through them only partially filtered down from the surface to the drains or to the subterranean water level existing lower in the earth.

BRISTOL PORT AND CHANNEL DOCKS.

FOR some years past (says the *Railway News*) considerable attention has been paid to the improvement of the navigation of the Avon and the approach to Bristol, and various plans have been suggested by eminent engineers for the improvement of the harbour and the establishment of docks at a more commodious position than at Bristol. In 1828 Mr. Milne proposed a masonry pier at Portishead. In 1839 Mr. Brunel proposed a floating pier at the same place, to be formed of large pontoons; and two years later Sir John Macneill proposed a breakwater pier. In 1855 the construction of a dock was suggested as suitable for the Portishead shore, and Mr. Neale further proposed that it should be a floating dock. The opposite side of the channel—viz., the Gloucestershire side—has been selected as an appropriate location for docks by a number of engineers. The late Mr. Rendel reported in favour of Avonmouth as the best ocean steam-packet terminal station in connection with the port of Bristol, but he insisted that whatever harbour was adopted the river Avon must be made to flow through it, in order to secure a sufficient scour by the flood of all tides. Mr. Hawkshaw's plan was to construct a steam dock at the mouth of the Avon for the accommodation of the ocean steamers, and to connect the dock with Bristol by a railway laid on the margin of the river. The result of inquiries which have been made at various times is that while Mr. Neale recommended permanent dock works at Portishead, Messrs. Rendel, Thornton, Howard, Hawkshaw, Page, Fowler, and Abernethy have recommended docks at Avonmouth, and Messrs. Milne & Brunel and Sir John MacNeill have been in favour of a pier at Portishead. In 1864 a new Act was passed, authorising the construction of docks at Avonmouth, and the works have for some time past been in progress, under the direction of Mr. Brunlees. The lock of the Chanel Dock at Avonmouth is 450ft. long and 85ft. wide. The dock itself is 1,400ft. long by 500ft. wide, the available water area being about sixteen acres, with a length of quay wall of 3,200ft. The depth of water over the Channel Dock cill at ordinary high water of neap tides is 36ft., and the depth of water in the dock is 23ft. 6in. Proposals have been made for constructing docks at Portishead, the lock of which is 450ft. long and 65ft. wide, the dock itself being 1,800ft. long and 500ft. wide, the area of water being equal to about twelve acres, and the length of quay wall 2,200ft., depth of water on cill 23ft. 6in., and in the dock 17ft. 6in.

NEW A.R.A.'s.—The Royal Academicians and Associates met on the evening of Thursday, 26th ult., to elect three A.R.A.'s. Messrs. H. S. Marks, F. Walker, and T. Woolner were chosen by clearly-pronounced majorities.

ISAMBARD KINGDOM BRUNEL.*

ISAMBARD KINGDOM BRUNEL was born on the 9th of April, 1806, the only son of Sir Mark Isambard Brunel, who, after some American experience as a civil engineer in America—consequent on his Royalist sympathies proving unacceptable to the Revolution, which at that time was paramount in France—had settled in this country seven years, and had been married nearly that time to an English lady, Miss Sophia Kingdom. On the completion of an important commission entrusted to him at Portsmouth by the Government, Sir Isambard Brunel removed to London, and continued to live in Lindsay-row, Chelsea, until the heavy responsibilities connected with the progress of the Thames Tunnel compelled him to live nearer thereto. At Chelsea young Brunel commenced his education, under the Rev. Weeden Butler, who resided in the neighbourhood—having been previously taught Euclid by his father, and exhibited considerable talent for drawing, even at the age of four years. We next find him at Dr. Morell's school, at Hove, near Brighton. An extract from one of his letters in 1820 reveals an early liking for the profession he adopted, or inherited. A passing and comparatively uninterested reference to the progress of his classical studies is followed by the description of "an amusing job" he had been about, viz., taking a plan of the town, which he had got "pretty exact." For the attainment of "a more exact plan," however, he requests the loan of his father's "long eighty foot tape." From Hove he proceeded for two years to the Collége Henri Quatre, at Paris, and in 1823 permanently took his position in his father's office. In 1825 the Thames Tunnel was commenced, and Sir Isambard's diary bears frequent witness to the energetic devotion displayed by his son under the many difficulties which attended its construction. In the accident which, on the 1st January, 1828, put a stop to the works for seven years, he nearly lost his life, and was most severely injured, remaining under medical treatment for several months. On his recovery, he applied himself with energy to his profession on his own account. His first "competition venture" was sending in four designs for the then contemplated Clifton Suspension Bridge. These, however, did not find favour with Telford, who had been requested to advise upon the plans submitted, and who, indeed, reported equally unfavourably of all; submitting a design himself in the new competition which followed, which was also in its turn rejected. Brunel was ultimately appointed engineer, but financial difficulties prevented the completion of the bridge until some time after his death.

In 1833 he commenced his career as a railway engineer in the service of the newly-started Great Western Railway Company. We cannot trace here the history of his long-continued exertions in behalf of that company. It differs little from the history of all who had to encounter and vanquish the obstinate resistance offered by those who, a few years later, with equal blindness, plunged into utopian schemes for the construction of new lines similar in all but the need for their establishment to those they had formerly opposed. Brunel's connection with the Great Western Company continued until 1851; he also planned other lines in the United Kingdom, and also in Italy and India.

His abstemiousness in everything but tobacco probably contributed in no slight degree to the enormous capacity for work which he possessed. At times he appears to have been able for weeks together to do with but two or three hours' sleep out of the four-and-twenty, and that frequently taken in his arm-chair or travelling carriage. His exertions in behalf of railway enterprise would alone have won him a first-class reputation, but his genius for work led him to seek for fresh triumphs in the field of ocean steam navigation. In 1836, mainly by his influence, the Great Western Steamship Company was formed, and in April, 1838, the *Great Western* successfully made her first voyage from Bristol to New York in fifteen days, with an expenditure of only three-fourths of her coal, to the great joy of her owners and the discomfiture of Dr. Lardner and others, who had advanced the opinion that Atlantic steamers could not carry sufficient coal for the voyage. The success of the *Great Western* led to the construction of the *Great Britain*, which was built of iron, and launched in 1844. This vessel, in which, with the exception of an experimental trial in the *Archimedes*, the screw-propeller was for the first time adopted, after successfully accomplishing several voyages, ran ashore in Dundrum Bay. She was rescued by Brunel, but the misfortune caused the collapse of the company, and the vessel passed into the hands of Messrs. Gibbs, Bright & Co., of Liverpool, who, after refitting her, started her again in 1851, as a regular steam-ship between Liverpool and Australia.

The success attending the adoption of the screw-propeller led, in 1841, to Brunel's appointment to conduct experiments for the Admiralty, with the view to the application of the principle to the ships of the Royal Navy. He appears to have met with the usual amount of red-tape opposition and petty ill-will, which all appear destined to encounter who are unfortunate enough to have dealings with Government officials, and although his exertions led to the ultimate successful adoption of the screw, his services were never acknowledged, either by any pecuniary or other recompense.

His last great enterprise, the building of the *Great Eastern*, was conceived by him shortly after his appointment as engineer to the Australian Mail Company in 1851. The misfortunes which so long appeared inseparable from all and everybody connected with the apparently unlucky ship are too fresh in the minds of our readers to need repetition. After ruining the company under whose auspices she was originally projected, and even when built refusing for a long time to move into the water, she was at length successfully floated in January, 1857. Even then, for a long time she continued to appear somewhat in the character of a white elephant, and her designer was not permitted to witness her triumphant career in the laying of the Atlantic cables. He appears, however, before her completion to have entertained some idea of her adoption of such a purpose, for when Cyrus Field came to England in 1856, in connection with the then proposed cable, and visited the *Great Eastern*, then nearly finished, Brunel said to him, "There is the ship to lay the Atlantic cable."

On September 5, 1869, while engaged in preparing the *Great Eastern* for sea, he was attacked with paralysis, and gradually sinking, died on the 15th of that month, in the 54th year of his age. A window to his memory has been erected in Westminster, and a statue, executed by Baron Marochetti, awaits a site, promised by the First Commissioner of Public Works. More lasting monuments to him, however, far exceeding even the memorials of his works, are the benefits which they won for science and commerce. The Atlantic cable itself must ever carry to and fro, with its thousand messages, some memory of Brunel's fame, for it is not too much to say that without his ship its successful completion would have been a thing yet to be accomplished.

As a lesser form of memorial, this biography by his son is very valuable. Its accuracy and completness are worthy of commendation, and the object of its author, viz., "to provide as far as possible the materials on which a just judgment of his career can be based," appears to us fully attained.

* "The Life of Isambard Kingdom Brunel." By ISAMBARD BRUNEL, B.C.L. London: Longmans & Co.

ON THE NEW ST. THOMAS'S HOSPITAL.

(*Concluded from page* 62.)

IT was thought desirable throughout the wards to have a smooth surface of flat ceiling, but throughout the corridors and a great portion of the hospital the arches and girders are left to show the construction, the soffits of the arches being finished with a setting coat of plastering. The joists and sleepers, or concrete and paving, are laid on the top of the Dennett arching in the ordinary way. The waggon-headed ceiling of the chapel and the groining of the aisles is also executed in the same material, the aisles having stone ribs. The thickness in the panels is 5in., and in the stiles 10in. The reason which induced me to adopt this mode of construction for the chapel roof was not only the satisfaction of having a real sound solid construction, but it afforded an opportunity of carrying up several flues to the apex of the roof, which must otherwise have cropped up in an objectionable mode on the balustrading. The flues are carried across the groining or aisles on the back of the main ribs, then up the piers of clerestory walls, and again on the back of the main roof. Provision being made for sweeping at certain points easy of access. I may here mention that the flues from all the low buildings are taken across the corridor ceilings, and carried up with the main building, thus avoiding all risk of smoke and disfigurement. The ceiling of the Governor's hall is constructed with iron girders and Dennett arching for the same reasons. The flues for the rooms on the lower floors had to be disposed of, and instead of interfering with the parapet and balustrading, were carried over the back of the cove, and taken out of the roof in the ordinary way. The "Dennett" material is certainly very handy in execution; it accommodates itself to any form of arch or groin; it is strong, has great resistance against fire, and, when set, does not exert any lateral pressure; but care must be taken, and a liberal allowance made for expansion during the process of setting, and, finally, I believe it is as cheap if not cheaper than any other fireproof construction. The superficial area of arching used at the hospital in floors and flats is about three hundred and thirty-seven thousand feet.

The rivetted iron girders, of which there are about 1,250 tons, were made in Belgium at the Selassin Works, and although not quite so neat in finish as one would wish (many being exposed to view), yet at the same time they are composed of excellent material, and stood the proof tests well. They were delivered very regularly, and the delay which so often occurs from the non-delivery of ironwork was avoided. The flat roofs over low buildings and corridors, which in many parts form terraces of communication, are constructed in a similar way. The surface of arching is covered with concrete, laid to the required fall, and then covered with asphalte—"Pilkington's patent," which consists of the introduction of a layer of felt between two coats of asphalte. The lower coat is laid in polinceon, about half an inch thick, and the upper coat in Seysell, half an inch thick, with flusbing of the same material. The whole, as well as the paving in the basement, has been executed by Mr. Pilkington in an excellent manner. The paving and channel stones used in the areas are the patent Victoria stone, composed of granite chippings and Portland cement cast in moulds, and indurated by a process somewhat similar to Mr. Ransome's. It forms a capital paving, and a considerable saving has been effected by using it in lieu of rubbed Yerk. The traffic in the areas is of course unimportant, but the paving in question has been severely tested in the Poultry and on Blackfriars Bridge, and is standing the test well. The corridors are paved with tiles one foot square and inch thick, in alternate squares of red and buff, with black berders. They are executed in Ransome's material specially indurated, and when one considers that this material is found most effectual as a grindstone, I am induced to expect that it will stand the effect of friction as well, if not better, than any natural stone. The cost of such paving bedded and jointed in Portland cement is very moderate. The quantity required will be about 30,000ft., and I do not think so good an effect could be produced in any other material with equal durability at so small a cost. The floors of wards are laid with wainscot oak as being non-absorbent, and the walls

* Read by Mr. HENRY CURREY, F.R.I.B.A., before the Royal Institute of British Architects, on Monday the 23rd ult.

are plastered with Parian cement for the same reason. It has been endeavoured to incorporate a tint with the finishing coat of the Parian, with a view to avoid the glare of the natural white colour, and painting hereafter. Certain experiments were tried, and it was found that with a backing of Portland cement and a setting coat only of Parian, a more uniform tint was produced than by using Parian throughout. Although great care has been taken in the manipulation, the result is not wholly satisfactory. Had we been able to wait until the walls were more completely dry, a more uniform tint would probably have been produced.

The ward windows are constructed in three divisions, as shown on sections, the lower part being to open in the usual way, and the upper sash drops to the depth of the transom, which is quite sufficient for clearing the upper stratum of air in the wards. The whole of these sashes and frames, and the greater portion of the doors, were made in Sweden by the firm of Messrs. Ekman. My assistant, Mr. Harris, went purposely to Sweden to inspect the works, and brought back a most satisfactory report of the machinery, drying chambers, and general capabilities of the establishment for turning out good work, and the result has fully justified the confidence placed in them.

The ground floor of one of the pavilions has been used up as a drying-room (by building up temporarily the various openings) in which all the floor boards and other joiners' work have been thoroughly seasoned. One of the many newspaper critics, seeing these openings built up, regretted that the governors were unable to utilize the whole of the hospital, and that some of the wards had consequently been built up. A little inquiry would have enlightened him and explained the reason of the temporary blockade.

In designing the joiners' work, all mouldings and quirks have been dispensed with as far as possible, as such parts only afford harbour for vermin. The wainscot floors are tongued with hoop-iron, the nail holes stopped with coloured putty, and prepared for waxing and polishing. The windows of the pavilions are glazed with plate-glass, with a view to a more equal temperature, and the corridors are glazed with flatted crown.

The warming and ventilating arrangements are indicated to some extent on the drawings hanging on the walls. It was determined to depend as much as possible on natural ventilation, avoiding all costly arrangements and fanciful theories, at the same time providing the means of changing the air during cold and boisterous weather and at night. The main extraction shaft is carried up in the well-hole of the staircases, and in this is placed the smoke-flue from the boiler, consisting of a wrought iron tube 15in. diameter. The boilers for warming purposes would not of course be available in the summer, but the furnace for the supply of hot water and baths would be continuous in its operation. In the upper part of this shaft are also placed the hot water cistern, and if found necessary, hot water coils will be added to assist the rarefaction. Shafts are carried from the ends of all the wards, both at the ceiling and floor level, and from the centre at the stove shaft hereafter mentioned, communicating with a horizontal trunk in the roof, which trunk is connected with the heated shaft previously referred to. To replace the air thus extracted, fresh air is introduced by means of zinc tubes laid between the Dennett arching and the floor boards, communicating with the stoves and hot water coils, thus passing over a cool surface in summer, and tempered in winter by contact with the heated surfaces before entering the wards, the whole admitting of regulation by valves. Each pavilion has its independent means of warming and ventilating, avoiding as much as possible all complication in the arrangement, but the pipes are so arranged that in the event of a break-down in any one block, its neighbour can come to its assistance during its temporary failure. A chamber is formed under the ceilings of the corridor in basement and ground floor, into which the whole of the rooms in the low intermediate buildings forming the out-patients' and casual departments are ventilated, and this chamber communicates at each pavilion with the main extraction shaft before described. The wards generally are warmed by three open fireplaces, aided in cold weather by an auxiliary system of hot water. The corridors and staircases are also warmed by hot water. The open fireplaces stand in the middle of the wards, with vertical shafts. These fireplaces might have been arranged against the outer walls, but bed space would thus have been sacrificed. The stoves might have been placed as they are, but with descending flues to the outer walls. This, however, would have involved great complication in the arrangement, and risk of smoke and difficulties in sweeping, and the piers, already small enough, would have been so riddled with flues that they would have been unequal to carry the weight imposed. It was therefore thought best to carry up a vertical shaft throughout. It may detract somewhat from the appearance of the wards, but it has, I think, great compensating advantages. The shafts are constructed, as shown on the drawings, with an outer case of cast iron, and a inner smoke tube 15in. diameter. The hot metal does not, therefore, come in contact with the atmosphere of the wards, but the space between the two tubes becomes an efficient ventilating shaft, which is connected as before with the main trunk in roof. The smoke tube is carried down to the basement, and is swept from below without disturbing the wards. The whole arrangement is capable of easy removal for repair. A cast iron socket is built into each floor, supported on two small bearers running from girder to girder, and the Dennett arching is made good to the same all round, thus avoiding any communication from floor to floor. The outer casing is of cast-iron, put up in pieces and bolted together, and is easily removed at any time should it be necessary to repair the smoke tubes. In the upper story the iron casing is discontinued, and a brick casing built on the concrete floor, which is more convenient for passing through the roof and carrying the external shaft. It will be observed that the three stoves go into one flue. This is made of ample dimensions, and a valve is provided at each stove to close the connection with the flues when the stove is not in use. As far as it can be tested in the present unfinished condition of the work, the arrangement works satisfactorily. The stoves are formed with an air chamber at the back, having a large heating surface of metal (but which cannot be heated sufficiently to vitiate the air) standing in a pan of water, somewhat similar to the Gurney stove. The ventilation of the water-closets and lavatories is entirely independent of the wards, and is carried up the shaft in the river turret, in which are placed the hot-water tanks for supply of baths and water coils. The stone shafts at the angles form the termination of the foul linen and dust shoots, which are carried right up to the external air. The ventilation of the museum and school buildings is on the same general principle, the ventilating and smoke shaft being contained in the tower at the southern end of the building. The whole of the warming and ventilating works have been most satisfactorily carried out by the well-known and experienced firm of Haden & Son, of Trowbridge, and I am glad to bear testimony to their ability and the careful and considerate attention to all works entrusted to them.

The risk of fire is reduced to a minimum, but considering that an alarm even of fire would act most injuriously on many cases, a system of fire mains and cocks is provided throughout the building. The cocks admit of being served either from the rising main or from the large tanks provided in the towers. A special main has been laid by the Southwark and Vauxhall Company to supply the building, and a constant service will, it is expected, be supplied; but in the event of any accident happening to the main, provision is made by an arrangement of back valves to supply the cocks from the tanks. These arrangements have been carried out by Messrs. Shand & Mason, whose name is a guarantee for their efficiency. The gas services have been executed by Messrs. Strode, and although not calling for any special description, I may say that they have been carried out in the usual satisfactory manner by that firm.

The lifts, of which there is one to each pavilion, demand a few words of explanation. They are constructed upon the hydraulic ram principle. A boring was made to a depth of 70ft., and lined in the usual manner for about 22ft. through the gravel with cast-iron cylinders to keep back the water, and from this point to the bottom through the clay the well is lined with brickwork. In this well is sunk a cast-iron cylinder, 11in. internal diameter, strongly bolted together in 9ft. lengths, and within this again comes a hollow ram, 9in. diameter, working through this cylinder, screwed together in 9ft. lengths. On the top of the ram the ascending room is attached, consisting of a strong iron frame with iron roof, all strongly trussed together and lined with match boarding. At the top and bottom of this room, on each side, are V guides, lined with gun metal, the top ones having springs to prevent oscillation or sudden shocks. At each side are suspending irons, to which are attached strong chains passing up a groove in the brickwork and over wheels 3ft. 8in. diameter to the counterbalances on each side; these counterbalances work in recesses, and are grooved to run in guide irons. The guide bars for the ascending rooms are of cast iron, placed the whole height to ensure a steady movement. A gear rod passes through the cage to control the lift, and self-stopping gear is attached. The lifts are worked by a fall of water from large tanks fixed in the roof of each block, 104ft. from basement, each tank containing 2,500 gallons. The stroke or rise of each lift is 63ft. The pressure of water is 45lb. per square inch, and the lifts are calculated to raise six persons each time. This principle has been adopted as affording the most perfect safety attainable. The overhead gear is placed at the sides in a chamber specially provided, so that in the event of any fracture thereof, no damage would arise to the cage. There is also one food lift to each block. They are upon the rack and piston principle. The machinery, which is in the basement, consists in each case of a cylinder, 11in. diameter, with piston and rack working in it, with tooth wheel and large drum wheel, on which is coiled the wire lifting rope, passing to the top of the building and over a one-grooved pulley to the cage, which has guides top and bottom; this cage runs in T-iron guides, fixed in each side of walls, from top to bottom of lift hole. A separate wire rope is attached to the top of cage, passing over grooved top wheel to the counterbalance, which is also guided on each side by angle iron guides. The lift is worked by a rod passing up at the corner and communicating with the valve at the bottom. The weight intended to be raised is 1 cwt. The height is 63ft., and these lifts are worked from the same tank as the passengers' lifts. They are easily controlled at any floor, and stop themselves, at the highest and lowest points. The whole of the lifting apparatus has been specially designed and carried out by Fred. Colyer & Co., Engineers, St. Mary's Iron Works, Leman-street, London, the whole of the work being of the most substantial character, and nothing has been neglected to ensure thorough efficiency, combined with perfect safety

The electric communication has been executed partly by Messrs. Reid, Brothers, of the City-road, and partly by Messrs. Moseley, and the ornamental ironwork by Messrs. Skidmore.

In conclusion, allow me to say a few words as regards the cost. The ultimate cost, exclusive of the site, will probably be about £400,000, including foundations and fittings, or £650 per bed, which, in the absence of any detailed explanation, appears to be a large sum; but if all extraneous buildings are allowed for, and the cost of one pavilion taken which accommodates 111 beds, it will be found that the amount would be reduced to £250 per bed, and considering the cubic allowance of space, the number of attached rooms provided, and the character of the work generally, such amount does not appear to me to be excessive. The cost of the building, exclusive of the concrete foundations and the enclosure railing, is about 9d. a cube foot. The contract, among other things, provides a large medical school building, a building for the training of nurses, large administrative offices for the civil department of the hospital, five residences and extensive out-patients' department, and the enclosure of 8½ acres of land with stone curb and iron railing and parapet walls.

I have now only to bear testimony to the excellent manner in which Messrs. Perry have carried out the work, and to thank Mr. Bullivant, the Clerk of Works, and all parties who have assisted me, for the zeal and ability with which they have performed their several duties.

DISCUSSION.

The PRESIDENT (Mr. T. H. Wyatt) said that whatever difference of opinion might exist as to the relative merits of the pavilion or other systems of hospital construction, there could be no question as to the merit attaching to Mr. Currey for the lucid way in which he had described the new S. Thomas's Hospital. There were several visitors of the medical profession in the room, and he would first call upon Dr. Balfour.

Dr. BALFOUR, having thanked the President for the opportunity of hearing Mr. Currey's

paper, and Mr. Currey for having given him the opportunity of personally inspecting the works, said he was very much struck with the great care which appeared to have been taken to provide for all the contingencies of the medical service and the school service of the hospital. Perhaps the highest compliment he could pay to Mr. Currey was to say that on only one point could he find anything that did not come up to his expectations. He was not quite prepared to endorse the opinion that the system of ventilation by shafts in the centre of the wards was perfect, because he feared that in the summer time, when the fires were not burning, and, consequently, when there would be no heat in the centre tube, the system of ventilation might possibly get out of order, and the foul atmosphere of one ward get into another ward. He was not aware that there was any arrangement to prevent such an occurrence. This, however, was the only point of detail which he considered open to criticism. The school arrangements were particularly good, and the care that had been paid to the general arrangement, and to the ventilation was (with the exception of the point alluded to) highly satisfactory.

Mr. EDWARD HALL, F.S.A., Fellow, said that Mr. Currey had not quite accurately described the arrangement of the plan of the Lariboisière Hospital at Paris. That hospital had its ward-blocks surrounding a central court. He thought Mr. Currey said that the ward-blocks extended at right angles to the central corridor. He (Mr. Hall) believed that that arrangement had been carried into effect in two or three hospitals in Great Britain. The first hospital in which the principle was adopted was that at Blackburn. The plan of the Lariboissière was that of a central court with corridors round three sides of that court, the administrative buildings being situated on the fourth or entrance side, the ward-blocks approached by the eastern corridor extending toward the east, and those approached by the western corridor extending westwards. He thought that that arrangement was worthy of a little more attention than it had hitherto received in this country, because the plan was considerably more compact, and allowed of better communication between the several blocks and the administrative department. Another point which he desired to submit to Mr. Currey's consideration was whether it was really most advantageous to cover the interior walls of the wards with Parian cement. At the time when the best mode of constructing hospitals was under discussion, it was considered that Parian cement was the best possible material for the purpose of coating the ward-walls, and that a highly-polished hard surface was greatly to be desired. But in one of the most important buildings of this kind which had been constructed (Chorlton-upon-Medlock) the walls were covered with lime-white, because the funds did not allow of the use of Parian cement; and it had been suggested of late years that it would be very much better to avoid the use of Parian cement, which, good as it was, was liable to absorb some of the miasma—a fault which it was highly necessary to avoid—and that if lime-white were generally adopted for this purpose, it would be possible to renew the surface of that coating periodically, while that material would also act as a preservative against infection. It would be well to bear in mind the many important points which Mr. Currey had only slightly touched upon. The question of the number of cubic feet of space allotted to each patient was very important. He believed Mr. Currey had given a larger number of cubic feet per bed in his wards than had been given in any other case. The distance between the pavilions had also been increased, but not, he thought, to an extent incommensurate with the extra height of the blocks.

Dr. FITZGERALD said he had been over the new buildings, and he was highly pleased with the whole arrangements, which were eminently satisfactory in nature and extent. The school and museum arrangements seemed particularly excellent, and compared very favourably with those at University College.

Dr. CARTER said he had had the advantage not only of hearing Mr. Currey's paper, but of accompanying that gentleman over the buildings several times. At the time when the removal and reconstruction of S. Thomas's Hospital were in contemplation, a note of alarm was sounded by a great medical authority—Brownlow-Moore—as to the danger of building hospitals as permanent structures, and the late Sir James Simpson expressed his fear that hospitals became saturated in course of years with the miasma thrown off by the sick, and ventured it as his opinion that the best plan would be to construct hospitals of a temporary nature, so that they could be destroyed at certain intervals and re-erected on other sites. The great weight of Sir James Simpson's name, he (Dr. Carter) thought, caused undue importance to be attached to his utterance on this matter, giving his conclusions a prominence not justified by the grounds from which he deduced them. As this new S. Thomas's Hospital was the most important work of the kind carried out as a *permanent* establishment since the expression of these opinions, he thought it would be some satisfaction and re-assurance to Mr. Currey and to architects generally when he said that it was the general opinion of the medical profession that Sir James Simpson, on the occasion mentioned, sounded an unnecessary note of alarm, and that there was every reason to believe that the new hospital might be kept as wholesome for all time as any building of its kind possibly could be. His (Dr. Carter's) colleague, Mr. Holmes, had lately contributed to the *Lancet* some criticisms of Sir James Simpson's remarks on this point, which would doubtless be found worth perusal by architects. As to the best material for coating the walls of the wards, he might say that lime-white had been used for the purpose in the new hospital built by the parish of St. Pancras at Hampstead, and since handed over to the Metropolitan Asylums Board; but he thought that with due care and frequent cleansing with a wet sponge, a smooth surface was infinitely preferable, for the products of the miasma escaping from the patients was most injurious when disturbed while in a dry state. He was highly satisfied with the accommodation and arrangements of the hospital, but had to criticise one small detail. He thought it would be found that there was not quite light enough in the operating theatres, and that more window-space would have to be provided before the surgeons felt quite at home in them. With this exception, however, he had no fault to find with Mr. Currey's arrangements. (Cheers.)

Professor DONALDSON complimented Mr. Currey upon the lucidity of his paper, as well as on the successful completion of so important a work. With regard to the observation by a previous speaker that the new S. Thomas's Hospital differed from the Lariboisière, it was true that the arrangement was different (necessarily so, on account of the site), but the principle was the same. With regard to the defective lighting of the operating theatres, that could easily be remedied. He begged leave to propose that the best thanks of the meeting be presented to Mr. Currey for the very interesting and lucid paper he had read. (Applause.)

Professor KERR said he had very great pleasure in seconding that vote of thanks. He thought they must all have felt that Mr. Currey was a singularly happy man to have got through this great work without a single difficulty. The reason of this might be that he had had a commission so liberal in its character, and had brought to bear upon the execution of the commission—he (the Professor) would not say a very thorough acquaintance with the subject, but a straightforward mode of doing business, and an absence of straining after effect, which two considerations went so far, as could be seen by Mr. Currey's example, to ensure success in such a matter. The description Mr. Currey had given of his work showed that he had, from the foundation to the vanes of his highest pinnacles, one object in view—to do his work with the utmost substantiality and with the utmost liberality, and he (the Professor) thought he had never heard or read the description of a transaction of building that carried more completely to his mind the appearance of everything having been done well and for the very best. (Hear, hear.) The site was one which had afforded Mr. Currey great liberty as regarded space; that was a thing which seldom fell to the lot of an architect. He had availed himself of the privilege in the most intelligent manner, and he (Professor Kerr) thought, from what he heard, that the public were universally inclined to consider this hospital to be a *chef d'œuvre* of its kind, and he personally thought it was one of the most popular works of the age as regarded its efficiency and the likelihood of its proving a success for the purpose for which it was intended. There was one point upon which he should like to say a word, especially as Mr. Ransome was present. He referred to Mr. Currey's use of artificial stone in this building. He (Professor Kerr) confessed that once or twice when he heard the matter mentioned he was inclined to doubt whether Mr. Currey was justified as an architect in using the artificial stone in the way he had done, but from Mr. Currey's description he was perfectly satisfied in that respect. In the way in which Mr. Currey had used that material he had fulfilled its proper purpose, and he need not fear to withstand any criticism which might be offered upon the subject from an artistic point of view. If he (the speaker) understood the matter aright, the capitals of the Corinthian columns were of artificial stone—and he might mention an incident which occurred with regard to these capitals. A certain stone-carver had been promised, as he considered, all the carving work of this hospital. He went on the ground one day and complained that he was being badly treated. The clerk of works, or the person who received him, asked him what he meant. The carver said, "I see Corinthian capitals fixed in their places which were not carved by me." The clerk of works told him that if he would accompany him to the shed he would see these Corinthian capitals by the hundred. They both went to the shed, where the carver was compelled to confess that at a little distance he could not distinguish the artificial stone capitals from those in Portland stone. This tribute was deserving to Mr. Ransome, because he could manufacture his stone so as to be, to all intents and purposes, *the* material which it professed to imitate. He believed these capitals were made solid, or very nearly so, and of such material as to equal the Portland stone. Mr. Currey mentioned the circumstance of this stone being superior to the natural material in the form of grindstones. It had been said that Nature did not undertake to find us in grindstones, but architects would be pleased to hear that Mr. Ransome had invented another stone which was superior to the one referred to, and if Mr. Currey had waited for a few years he would have had a better stone (laughter). He (Professor Kerr) had seen specimens of the new stone of the same kind as Portland stone and of the same kind as certain "barnacles," and he thought that when the time came architects and builders would all feel very much surprised at the extraordinary effects and qualities of this new stone. He understood Mr. Currey to say that the corridors were paved with artificial stone, as it was found to wear better than tiles. That was well worth understanding. Of course they were all acquainted with tile-paving, than which, for ornamental purposes, nothing could be better; but for paving on a large scale, this artificial stone was far superior. It was not a laminated stone, and that, perhaps, was the reason of its durability; but he should like to hear Mr. Currey say whether it was equal to Portland stone as a paving. The very important question of hospital construction which had been raised, and the able discussion by the medical gentlemen in the room as to the best surface for the walls of the wards, had been very interesting. Those of them who had not given much attention to the particular question might have suggested that the ordinary rule might be applicable to hospitals—that Parian cement with a polished surface, being non-absorbent, was liable to a certain disadvantage as regarded the trickling of the water of condensation down the surface; but the propriety of using a polished surface for the walls of a hospital ward was now, to him, unquestionable. Some of them, too, might have suggested that if the lime-white were necessary as a mere coating on the surface, the wall itself might be of Parian cement with the lime over it. Dr. Carter said he preferred the polished surface, as capable of being cleaned when required without much trouble; but a lime surface involved greater trouble in cleaning (or rather removal), and was attended with much greater risk both to the men employed in the work and to the patients in other parts of the hospital. He heartily seconded the resolution moved by Professor Donaldson (Applause).

Mr. JENNINGS thought that on such occasions as that they should look at all the points in connection with the subject. He had not heard any notice taken of any other covering for the walls than Parian cement or lime-whiting. In Liverpool, tiles and enamelled slate were much used, and it was a question whether glazed tiles were not capable of being used for the walls of wards. It was perfectly clear that a surface of glazed tiles or enamelled slate would not be liable to retain infectious matter, but, on the other hand, they would be still further liable to the evils of

condensation of the atmosphere unless the ventilation was perfect. He imagined, however, that the provisions made for ventilation by Mr. Currey would be sufficient to carry off the air in such a state as to prevent condensation. He did not see that Mr. Currey had made any special provisions for carrying off the carbonic acid gas, which would not have to be carried off from the upper but from the lower parts of the wards; nor was he aware whether Mr. Currey considered that the opening of the tubes to the edges would afford sufficient ventilation to the wards in summer. He was quite aware that the carbonic acid gas would sometimes pass up to the top, owing to certain circumstances, and that it would not always remain at the bottom. He should like to know what precautions were adopted for carrying out the carbonic acid gas under such circumstances, and when there were no fires? At Sir Charles Barry's dining room the ventilation now and then acted the wrong way, and put out the gas, and the same result had often been experienced by all present who had tried to heat by hot chambers.

Mr. FOWLER said that the admirable paper read by Mr. Currey suggested to his mind three subjects of congratulation. Firstly, he congratulated Mr. Currey on the satisfactory conclusion of so perfect a monument as the new hospital might fairly be considered. (Hear, hear.) Secondly, he thought they should congratulate the profession generally on the liberality with which the Governors of the Hospital had enabled their architect to carry out the work. (Hear, hear.) The third party who were to be congratulated were the poor, on having the means of such a magnificient hospital put before them. Twenty years ago the subject of hospital accommodation was not so thoroughly understood as it was now. He supposed they might now think that they had arrived at some tolerably definite ideas upon the subject; but twenty years ago it was a very open question as to what the arrangement should be. In the building of a hospital with which he was familiar (but of which he was not the architect, and therefore he would not name it), the wrong plan was, undoubtedly, ultimately adopted, after a long discussion of the merits of the various methods of arrangement. From what had been clearly demonstrated in subsequent examples of hospital construction, it was impossible that the hospital referred to could have been a success, for the architect was limited to an expenditure of about £100 per bed, though twenty years ago that was considered a very liberal outlay. The expense of the building cubed out was little more than half that of Mr. Currey's S. Thomas's Hospital (9d. per foot cube), viz., 5½d. per foot cube. It was now known that that scale of expenditure was too low to provide an efficient establishment, and it was a matter on which the profession was to be congratulated that in twenty years it had made such satisfactory progress.

DR. MASSEY said he thought it was quite unnecessary for him to speak of the various merits of the new hospital, for they were so very numerous. With regard to the ward construction, he might, however, say one or two words. Like the rest of the buildings, the wards had a great many merits. The lifts being constructed separately from the wards was a great advantage, and he thought the floors would prove as non-absorbent as the walls, being of well-polished solid oak, fitted together with the accuracy of a piece of cabinet work. The lavatories and water-closets at the ends of the wards were admirably ventilated and thoroughly cut off from the wards. He thought, however, that there were some points in the ventilation that he should have liked to have heard a little more fully discussed. Mr. Currey had not stated the proportion of the outlet to the inlet area. He (Dr. Massey) supposed there must have been some proportion fixed upon. Neither had Mr. Currey stated the proportion of both inlet and outlet area, either to the size of the wards or the number of patients in the wards. The general system of ventilation adopted, he (the speaker) should have liked to have heard a little more about. It appeared to him that there were summer and winter ventilations—the former, he assumed, by the windows (and nothing could be better); but with regard to the winter ventilation it appeared to him not quite so clear that it would work well. There were two methods of inlet, as he understood, the one along the floor in connection with hot water coils, the other by direct communication with the stoves. It seemed to him that heating all the inlet air in this way, unless it was done with great care, would render it too dry for the use of the patients. Moreover, the outlets were, as he understood, at the end of the ward, not in the end walls, but in the side walls, and likewise round the chimney. He also understood that the air escaping through these outlets at the ends of the wards would go through long horizontal flues into a common tube, and that, in fact, the place would be ventilated somewhat on what was known as Jebb's principle—the principle on which so many gaols were ventilated, and to which there were grave objections. The air that was warmed at the stoves before distribution came into the ward in close proximity to the outlet chimney, beneath which chimney there were gas jets, and he thought that the hot air, from its inlet being so near to these gas jets, would be to a great extent lost by being sucked up the outlet chimney.

DR. BALFOUR asked whether there was anything to prevent the foul air from one ward getting into another.

Mr. CURREY said he did not think such an occurrence possible.

The PRESIDENT (Mr. T. H. Wyatt) said that for several years he had given a good deal of attention to the study of hospital construction, and he had no hesitation in saying that Parian cement was by far the best material for coating the walls of the wards. At the Middlesex Hospital several years ago that material was used; it was sponged down regularly at intervals, and the hospital authorities had never had the slightest difficulty with regard to condensation. He could not at all conceive that a rough surface was advisable for such a purpose. He had great pleasure in going over the hospital a day or two ago with Mr. Currey. He considered that the construction of the hospital was excellent in every respect.

The thanks of the meeting having been tendered to Mr. Currey, that gentleman said he thanked the meeting for their kind appreciation of his architectural services in connection with the hospital. In replying to the points raised in the discussion, he referred, in the first place, to the shafts in the centre of the ward. It was not intended, he said, to depend on these shafts for the ventilation, but the shafts being there to subserve another purpose it was determined to utilise them also, if possible, for purposes of ventilation. The main means of ventilation were provided at the two ends of each ward, both at top and bottom, by much larger shafts. A rarefying power in these shafts would be got both night and day, summer and winter, because they were warmed by the furnace for the heating of the baths. Mr. Hall was quite right in his criticism about the Lariboisiere Hospital. The Parian cement question had, he thought, been fully disposed of by the medical gentlemen present. The wards of the old S. Thomas's were of Keene's cement, and were regularly washed down every summer. An objection with regard to the use of tiles for this purpose was that there were so many joints, which would harbour vermin. Of course enamelled slate, in much larger pieces than the size of the tiles, got rid, to some extent, of that difficulty. To the best of his recollection, the inlets for fresh air had an area of about 50in. to each patient, and the outlet area was much larger. With regard to the deficiency of light in the operating theatres, that could of course be easily remedied.

The PRESIDENT then announced that the next meeting would take place on February 6th (Monday next), when a paper will be read by Mr. E. B. Denison, Q.C., "On Domes."

GOSSIP FROM GLASGOW.

[FROM OUR SPECIAL CORRESPONDENT.]

HAMLET had some hope that a great man's memory might outlive his life half a year—if he built churches. Had Hamlet lived nowadays, and, to "recover his wits," been sent to Glasgow instead of to England, he possibly might recover them this much, that henceforth it would not be in the churches a man had built he would seek the perpetuation of his memory, for he would find that sometimes the man lived longer than the church. One of the most able architects that has at any time practiced in Glasgow was William Stark, who flourished about the beginning of the century. Among his principal works is S. George's Church; and there is a looming probability that some of those who saw the laying of its foundation-stone may see also the disinterring of it. A proposal to raze the church has been before the Town Council, "the head and front of the offending" being that, lying like an island at the mouth of a river, it necessitates West George-street, in debouching on Buchanan-street, to divide in two and diverge by each side of it. The spire, conceived in the imagination of an artist that was akin to a poet's, is the most original, unique, and perhaps the most beautiful in the city, and with Hamilton's palatial Club-house—grand in its general effect, although somewhat crude in its details—composes a charming pictorial "bit" in our civic scenery. Whether Hamilton, the later artist, had in his mind's eye this picture, it is these two buildings, not individually but in composition, that lift Buchanan-street—the Regent-street of Glasgow—out of the low level of a dull monotony. The spire, however, is the more valuable and independent, relieving the line of a ragged horizontality, and of itself sufficient to give picturesqueness to the street. S. George's Church appears in a no less important aspect as the terminus of a vista from George-street East, the street which at no great distance is the northern boundary of our principal square—our intramural garden and sole statue-site. And yet I have heard it argued that it obstructed the view—the view being an horizon of the "croon o' the causey." There are few buildings in Glasgow, certainly very few churches, either as features in the scenery to the ordinary passer-by, or as objects of special regard to the educated eye, that we can afford less to part with than S. George's Church. Its composition is at once stately and picturesque, its detail large, simple, and singularly expressive; and when Italian architecture is running rank riot in wanton extravagance, there is something refreshing in the occasional study of a design so thoroughly independent of "loudly" emphasized parts, multiplicity of mouldings, or meretricious carving, and, withal, imposing. Stark designed in the large, broad manner, not piecing as a cabinet-maker, but building as an architect. As his material was stone, his workmanship was mason-work. His designs are as free from prettiness as pettiness. They have no feminine finery about them, no weakness or falsity to smother or conceal by an overlay of "ornament." They are rich in that rarest of beauty, the "beauty that unadorned is adorned the most"—the beauty of truth.

It is perhaps not too much to say that the best modern buildings in Glasgow are by Stark. His other chief works are the Jail, the Old Lunatic Asylum, and the Hunterian Museum; and, strange to say, the evil genius that threatens St. George's Church has followed these also. The jail was designed when Greek architecture was little understood and less practised, and although suffering much from not being placed upon the platform that the architect intended, it left his hands a grand example of monumental art—simple, severe and majestic. It early excited the admiration of Hamilton, the architect of that great Greek work, the High School, Edinburgh. Of late years it has been tinkered and cobbled and patched to meet certain necessities, a torture that Greek is, of all styles, the least capable of bearing.

> The roof's unbroken line,
> The long majestic march, and energy divine,

has been destroyed that height of ceiling and ventilation might be given to miserable Law Courts that in every sense are unworthy of the sacrifice. A rugged sky-line has robbed the building of half its dignity—the "entire and perfect chrysolite" is broken. A new bridge in the neighbourhood of the jail will shortly be opened, and it is to be hoped that the new levels of roadway will be such as will give to Stark's great work a long desiderated elevation. The old Lunatic Asylum has been converted into a workhouse, and that, of course, necessitated many alterations and additions. Stark's plan was a rotunda crowned by a cupola, and with arms radiating from it. The arms have much outgrown their original proportion, and offices for this and that purpose have so clustered like parasites about the central building that the harmony which was first supreme is now crushed out. The dome—as original in its design as is the spire of St. George's Church—is, however, from many points still a "leading feature" in our stone and lime scenery.* The Hunterian Museum—an exquisite gem—is now as if it had never been.

> The solemn temple,
> Yea, all which it inherit, hath dissolved,
> And, like an insubstantial pageant faded,
> Left not a rack behind.

This is literally the case. Not only the seen but the unseen has been removed: the very foundation has been dug out.

> The deep foundations that we lay,
> Time ploughs them up, and not a trace remains.
> We build with what we deem eternal rock:
> A distant age asks where the fabric stood:
> And in the dust, sifted and searched in vain,
> The undiscoverable secret sleeps.

* It would be ungracious to cast any reflections on the architects who have designed the alterations in the lunatic asylum and the jail. They were fettered by inexorable conditions, and could have little pleasure in their work. I believe that they all venerate the genius of Stark, and would much rather have commissions for new work than for altering his.

To quote to-day's newspaper, "a line of rails is being laid on the site of the Hunterian Museum;" in other words, there is now the railway "chair" where was once the seat of learning. Railway "sleepers" do not dream of art: the dome and portico were in the way, and the iron horse of Stephenson was a more resistless assailant to Classic walls than was even the wooden one of Epeus.†

With Stark's Hunterian Museum has perished an architectual work of the very highest merit. Can anything be done to save his admirable spire? The church itself from several circumstances—perhaps partly from parsimony, and partly from the situation being at the time of building on the very fringe of the city—is, except in the façade towards Buchanan-street, as bare as a barn, and I think few things could have given the architect greater pleasure than to have seen it as thoroughly swept away as is his Hunterian Museum. Indeed, it is the taking away of the church, and of the church only, that is really wanted, if the only object intended is to facilitate the traffic; and were the street-level of the spire pierced, as is that of S. Mary's, it might be made serviceable for several purposes—a receptacle of a statue or a drinking-fountain, a place of shelter from a passing shower or of safety from two passing omnibuses. This is, however, a minor plea; the argument for the preservation of the spire is its excellence in itself, and its value in giving a pictorial cast to its locality.

There are buildings, however, shorter-lived than even churches and museums. On the 20th of September last, in the neighbouring burgh of Hillhead, a "tenement" fell while it was being built. In its fall six workmen were killed, and at the last held Circuit Court of Justiciary, David Law, sen., and David Law, jun., they having acquired from the City of Glasgow Bank a right to erect said tenement, were tried for "culpable homicide and culpable violation or neglect of duty." The indictment set forth that "the walls were carelessly or insufficiently founded, and not built of sufficient materials; or the tenement was otherwise built in an unsuitable manner." After an examination of from forty to fifty witnesses—labourers, operative and master masons, civil and military engineers, timber-merchants, quarry-masters, architects, and although last not least, a measurer—the jury, after a deliberation extending over fifty minutes, returned a verdict, unanimously finding David Law, sen., "Not Guilty," and by a majority finding the charge against David Law, jun., "Not Proven." I subjoin part of the evidence of one of the witnesses for the defence, and allow my readers to deduce what they can from it. He deposed that he had received instructions from a gentleman who represented the City of Glasgow Bank, to "come and go" about the Messrs. Law's buildings; that he understood "come and go" that he was not to be too rigid in insisting on the work being of a first-class character; that he granted certificates for the building; that for the house which fell there was no specification, nor any statement regarding the quality of the work; that so far as he knew the work was not supervised by any architect; and that he understood that Law's sons were the architects. As, according to the newspaper report, this last statement was received with "laughter," it would appear that the proper functions of the profession are really beginning to be recognised. Whoever has been to blame, six lives have been lost, and at least the operative masons are dissatisfied with the verdict. On the evening of the 14th of January they held a meeting in the Trades Hall, at which it was resolved—"That this meeting appoint a committee, with power to add to its number, for the purpose of obtaining the moral support of the leading working-men of Glasgow and suburbs, with the view of bringing the Hillhead catastrophe, with the legal blemishes of the trial, significantly before the public, and to memorialise the Home Secretary for a special inquiry on the late decision." Now that the operative masons are taking action, it may be asked why was it that those operatives who deposed to the building being dangerous nevertheless remained to work at it? Had there been an attempted reduction of wages they probably would have left.

I said some time ago that the Clydesdale Banking Company intended to build new offices in S. Vincent-place. It has since invited one London, one Edinburgh, and two Glasgow architects to compete in making designs. I understand that each competitor is to be paid for his work. The site is on the north side of one of our widest streets, and hence affords an excellent opportunity for architectural effect.

Dr. Zerffi has been recently lecturing in Glasgow, Paisley, and Greenock. At Paisley he complimented the architect of the lecture-room (Mr. Honyman, of Glasgow), on its merits as a work of Grecian architecture.

The annual exhibition of the Glasgow Institute of Fine Arts will be inaugurated on Monday evening, 30th of January, by "a full-dress *conversazione*." Those who have been favoured with "a private view" say, as they have said for years past, that this is the best exhibition ever opened by the Institute.

NEW ELEMENTS OF HAND-RAILING.—PLATE XX.

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page 64.*)

PLATE 20.—QUARTER-CIRCLE STAIRS—WREATH IN TWO PIECES.

FIG. 1 shows ground plan. Centre line of rail struck with a radius equal to one step and a half.

This arrangement gives three balusters on landing. The rail may be four or six inches wide. The concave side of wreath will present a curved line, having neither cripple nor deformity. The grain of the wood runs nearly in the same direction as that of straight shanks.

Let the quarter circle be divided into two equal parts. This makes the joint at C; so that one mould answers for both pieces of wreath. Draw tangent through joint, and square with C O. This gives four tangents of equal length, as shown by A, B, C, D, E. These are unfolded at Fig. 2.

Have the two square steps and landing stand in same position as those on plan. This done, draw pitches cutting at T and L. Join T L (and not the corner, as shown by mistake of engraver.)

Then the pitches H L K, on lower part of wreath, are equal to those above—showing that one mould answers both pieces.

Find height, by drawing from joint K, which gives A H. Next find a direction for ordinate by extending H L, cutting at 2, which gives A 2.

Fig. 3 shows construction of mould.

Let O A E be a right angle. Make its sides equal O A, Fig. 1. Join O E. Let O C equal O A. Make A B equal one of the tangents on plan. Join B C. Let A 2 equal coresponding letters on the right. Join 2 C extended. Let seat be drawn through O, cutting at P, and square with ordinate.

Next, draw from A and B parallel with ordinate. Make P R, the height, equal that of A H on right. Join R V. This is the pitch.

The elliptic curves are more readily obtained by drawing the pitch through O, and parallel with P V. Then extend seat, and let O S equal O A. This done, set off on each side of S half width of rail.

Now draw square with seat cutting pitch, and we have the wide end of elliptic.

The drawing is now ready to lay a board on for the mould. See that the tangents K, L, H agree with pitches on right having corresponding letters. Square sections show the joints and application of bevels. Cut the slab off the shank, and work it to bevel. Draw a line through half thickness of rail as shown. Continue this along beveled edge, and square with joint. Transfer H 6 to it. Mark pitch, similar to that shown on left.

Be careful to make no mistake in application of bevels. The mould, as it now lies, represents upper surface of lower piece of wreath. This answers for piece above, by reversing.

The strings for these stairs may be plank.

The cylinder staved.

The joints should be screwed from the back.

* This series of articles is a reproduction of ROBERT RIDDELL'S work on the subject, published in Philadelphia, and by Trubner and Co., London.

We hear that there is some likelihood of the removal of the Knightsbridge Barracks, a scheme being again under consideration for building first-class residences on the land it now occupies.

DECORATIVE PROCESSES.

By "An Experienced Workman."

(*Continued from page 70.*)

WE have now to describe the operation or process of graining oak by the oil colour method. It is a commonly-received opinion amongst a certain class of architects and others that oak graining is a mere mechanical art, and that, as a natural consequence, any person of average intelligence may execute such works. No greater mistake could possible be made. It is true that numerous machines have been made and patented for effecting this purpose, an account of which we purpose giving in our next article; but with the single exception of one patent—which only professes to assist the grainer—the whole of them are mere makeshifts, none of them finish the work as they profess to do, but require the hand of the highly skilled workman to piece up and patch the work after them. There is also in all machine work of any description, whether applied to graining or any other process, an absence of the individual character or originality which marks the production of the individual mind. There is a charm and a feeling about work executed by the hand which gives it a value no mere machine work can possess. As we have before remarked, the grain and markings of oak are so varied in form that no two pieces can be found exactly alike. Now machine work, from its very nature, necessitates a repetition of pattern, which cannot be avoided. Hand-work, on the contrary, can imitate every variety and follow nature so closely that no two pieces need be alike. There is also in hand-work a wide scope for the inventive faculty and the exercise of good taste (both in form and colour) and skilful workmanship. As a rule, strong contrasts between the ground and the graining colour should be avoided. The figure and grain should of course be seen clearly, but only so clearly as to be distinct without interfering with the general and uniform quietness of tone necessary to fulfil the conditions required by the laws of harmony and good taste. Violent contrasts and gaudy colouring are always vulgar, brilliancy and richness of colour are not necessarily vulgar; it is the absence of the guiding power of knowledge and pure taste in their arrangement which degrades them to the rank of vulgarity. In this respect the colours of woods are the same as any other colours as regards decorative treatment, and require the same care in handling, or else discord is sure to result. Too much care cannot be bestowed in avoiding these errors in colour and form. We have before spoken of the importance of good combing, and of the various kinds of combs used; we now proceed to describe how the work is done. The graining colour is brushed over the work in the ordinary manner with a pound-brush, care being taken not to put too much colour on, or else it is very liable to be dirty. A dry duster is now used to stipple with, which, if properly done, will distribute the colour evenly; it is now ready for combing. In the real oak it will be found, as a rule, that the grain is invariably coarser on one side of the panel than the other; this arises from the very nature of the growth of the tree; it is, therefore, well to imitate this pattern, and in order to do so we take first a medium or coarse-cut gutta-percha comb, and draw it down one side of the panel; then use a finer one to complete it. This comb will leave the marks of the grain in clear unbroken lines from top to bottom of the panel. We now take a fine steel comb and go over the whole of the previous combing; but in drawing this comb down, we either move it in a slanting or diagonal direction across the previous grain, or draw it down with a quick and short wavy motion or curl; both the former and the latter motion will break up the long lines left by the gutta-percha comb into short bits, which of course represent the pores or grains of the real wood. It will be obvious that there are several other motions of the comb having the same end in view; and by using the gutta-percha or cork combs in conjunction with the fine steel an infinite variety of grain may be produced. Some grainers are in the habit of using the coarse steel combs with one or more folds of thin rag placed over the ends of the teeth; but this is a style of combing which has nothing to recommend it, and very much may be said against its use. A natural variation in the grain may be produced by one comb alone, according to the manner in which it is held. For instance, if we take a coarse or broad-toothed gutta-percha comb, and commence at the top of a panel with the comb placed at its full width: if drawn down in this position it will leave a grain of the same width as the width of the teeth; but if we start with the full width, and gradually turn the comb or slightly incline it to one side—that is to say, on its edge, we thereby graduate the grain from coarse to fine at pleasure, and by holding the comb at a certain inclination we may actually make very fine grain with the coarse comb. This style of combing is very useful for varying the grain upon the rails and stiles of doors or other woodwork, and for defining the joints, and a very great variety of grain may be thus produced. A very important point, requiring strict attention, is the formation of the joints in the wood, as much of the effect of otherwise good work is lost in consequence of neglect in this respect. In looking at a real oak door, the joints of the stiles and rails are clearly and sharply defined, not by any defect of workmanship, but by the difference in the run of the grain, the stiles being perpendicular, and the rails horizontal. The rails being cut sharp off by the stiles, show a perfectly straight line. The light also acts differently upon the two, simply because the grain or fibre of the wood is exposed to its influence under different aspects. This also tends to produce a difference in the depth of the colour of rails and stiles, and panels also. It will be evident that no imitations can be considered really good except they include these seemingly unimportant points.

It is a common practice for grainers to imitate a broad piece of heart or sap of oak upon the back rail of almost every door they do, and many of them are not even content with that, but daub the stiles over from top to bottom with it also. There is nothing so vulgar or in such bad taste. Now if the joiner in making an oak door was to put such wood into the rails and stiles, the work would be at once condemned by the architect, and very properly so too, simply because this part of the oak is not suitable for the purpose, and is never used in good work. We like to see the heart of oak well imitated, but it should only be done upon those parts of the work on which it would appear on a real oak door, namely, on the edges of the doors and on mouldings. On these parts the joiner cannot avoid it, because we see as it were two sides of a square; for it depends upon how the tree is cut into planks as to whether the board will show the grain and figure alone, or whether the heart and sap is seen. If we examine the stile of an oak door and we see grain and figure on the stile proper, we are sure to see heart or sap upon the edge of it. The wood may, of conrse, be cut so that we get both heart and figure together, but in this form it is very rarely used, except for boat building and for coffins, and never for doors. This fact should be borne in mind by the grainer; if it is, and he strives to assimilate his work to what is right and usual in the real wood, there can be no doubt but that he will produce better work, and it will be more in keeping with the real. There is a vulgar pretentiousness about what we may call the sappy style of work which is very undesirable.

The work being combed will now require to be figured. These figures, as a rule, cross the grain more or less abruptly, and of course of different shapes, sizes, and forms, a knowledge of which can only be acquired by study of the real wood. The figure may be wiped out with a piece of soft rag, held tight over the thumb-nail. This should have two or three folds over the nail, the superfluous rag being held by the other hand to prevent it hanging down and smearing the grain; and every time a figure is wiped the rag should be moved slightly, so that the same part of the rag will not be used twice, thus insuring clean work. It will often happen that the thumb-nail will get broken, or is too weak to stand the work; in these cases, or, in fact, in any case, a good substitute or artificial thumb-nail may be made of gutta-percha, thus: A piece of thin sheet gutta-percha is put into warm water, and while soft is wrapped around the end of the thumb up to the first joint. It is then pressed with the hand, so as to fit and take the shape of the thumb and nail. This cannot be done at one heating, but will have to be put into the hot water again, and the end pinched and squeezed into form to the shape of the nail, and to fit easy upon the thumb. When this gets hard it may be trimmed into perfect form with a penknife. This artificial nail will answer the purpose admirably if properly made; and even when the natural nail is good the gutta-percha will serve to save it from injury. Good figuring may also be done by using the blank end of the steel comb with a rag folded over its edge. We have also used a piece of gutta-percha to take out the lights. This should be square-ended, about one inch wide, and three or four inches long. Using this, instead of the thumb-nail, we have made very successful work of a certain class, but not of the best. Many grainers use a piece of thin horn, in shape something like a spatula, about three or four inches long and three quarters of an inch wide, with rounded ends, and quite flexible. With this tool the figure is cut or scooped out—we know of no other word which so aptly describes the motion required to effect this—a sort of quick, side-long motion, very difficult to describe and requiring a very considerable amount of practice before it can be worked with any success. There is, however, the same objection to this tool as may be urged against the gutta-percha for figuring, namely, that neither of them take the colour clean away, but leave an accumulation of colour on the edge of the figure, which is fatal to good work, and therefore we cannot honestly recommend the use of any method but the wiping out with the thumb-nail or its substitute. When the figure is wiped out, it will require to be softened. By softening, we mean the imitation of those half shades seen upon and about the figures in the real wood. Between and around the lights or figure in oak there is always a lighter tint of colour; this arises from the fact that immediately next the lights or figure the pore or grain is invariably darker than it is in the plain parts or spaces between the figure; and this is imitated by doubling a piece of rag into a small roll, and with the side of this the grain is partially wiped away, but not to the extent of taking off the whole of the grain. The grain must still be seen, but of course will not appear nor be as dark as it is on those parts on which it has not been disturbed; and this is exactly the appearance of the real wood. It is only by strict attention to these small matters that success is obtained.

We now come to a recent but most admirable system of graining oak by means of over-combing, which is worked exactly the reverse of any of the foregoing methods; that is to say, the figure is first wiped out, and the combing or grain is done afterwards, when the graining colour is dry, in this wise: The graining colour is mixed somewhat thinner than for ordinary graining, and is brushed over the work sparingly, leaving it just sufficiently strong to show a clear distinction between the ground and the colour. The

light or figure is then softened by drawing the end of a flat hog-hair fitch or a small thin mottler across each figure, and slightly softening with the badger-hair softener. The figure is then broken up a little with fine lines across it in parts, such as may be seen in the real wood; but previous to wiping out the figure streaks of light should be wiped out and softened on one side of the panel or across the stiles, in imitation of the reflective lights seen in oak. The colour should also be partially wiped off the rails or stiles at their junction; this tends to define the joint. The colour is now let to dry hard, when it will be ready for over-combing,—that is combing or graining over the figure (hence its name), and this will have to be done somewhat differently to the ordinary combing. As thus: The colour is rubbed in as before, and combed solely with the gutta-percha combs, but these are specially cut for the purpose; they are best about 2in. wide. The first must be cut with teeth about three-sixteenths of an inch in width, the next one-eighth, and the third about one-sixteenth. The broad-toothed comb is first used, and must be drawn down the panel with a wavy motion in short or long curls; either will answer our purpose now. The next size of comb is then drawn straight down—the straighter the better. This has the effect of breaking the wavy combing into short and long straight bits, similar to the pores or grain of the real wood. Both the first and second combing may be varied by holding the comb in a slanting direction, and may be fine or coarse, according to the width of the combs used; now take a soft rag folded, and with this partially clear off the grain which runs over the figure, leaving only a sufficient quantity crossing the light or figure to be just distinguished exactly as it appears upon the figure in real oak. The grain is also wiped off in parts on the plain spaces between the figure, in order to break it up and take away any apparent formality. If this method be well and properly done, a thoroughly deceptive imitation may be produced, and except this end be kept in view no really good work will result. In combing a door or other work, we have before spoken of the importance of clearly defining the joints, and we may add that we very often see good doors spoiled from inattention to this point. It will often happen that the joints of the rails and stiles are not exactly level with the mouldings. Mouldings in some cases are planted partly on the stile; in these cases the joint will be a certain distance, as it were, up the centre stiles and inside the back rail, while in ordinary doors, where the mouldings do not project beyond the panel, the joint is not covered, but is uniform with the edge of the stile. Grainers are but too apt to disregard the difference between the two, and are thus led to make false joints, and in nine cases out of ten the true joint will in time open, and thus we have apparently two joints instead of one. The joints should never be made in any other position but where the joints actually occur in the wood of which the door is made.

(To be continued.)

WINCHESTER TOWN-HALL COMPETITION DESIGNS.

THE designs which have been submitted in competition for the proposed new Guildhall and public buildings include, as usually is the case, a variety of ideas, but few well-considered plans, and fewer still that can lay claim to that combination of essentials which is needed for the special object in view. In no case, it may be asserted, do we find the combined requisites of a well-arranged plan and suitable exterior treatment. In one or the other of these necessary conditions they all seem to us to err. And yet we would not speak disparagingly of a collection which numbers nearly 50 designs, and which necessarily embraces a large amount of thought, trained skill, and laborious execution. When we recollect that each of these designs is illustrated and explained by nearly a dozen drawings, and that the combined labour this collection represents may be estimated by years, not months only, a fair idea of the labour and expenditure entailed may be gained, and the corporation and citizens of Winchester may well congratulate themselves on this response to their invitation, which is even larger than the bait they held out could warrant.

The designs may be considered, for the purpose of review, first, as regards *arrangement*, and secondly as to *external character* or style; and they may be further divided or distinguished by the position assigned in the several plans to the Assembly Room, a feature of considerable importance, not only on account of its relative size in the structure, but its value as a local requirement, thereby entailing upon the architect much careful consideration. The positions assigned to the Assembly Hall are as varied as the cardinal sides of the quadrangular space at disposal. As six of the designs have been distinguished as "recommended," we will first consider their merits, real or assumed. No. 1, "Tria Juncta in Uno," has a compact plan, and the arrangement appears to be economical. The Assembly Room is provided on the 1st floor. The style adopted is a sort of Italian Gothic, freely treated. No. 8, "Caer Gwent," has also an Assembly Hall in the front, on the 1st floor, and the distribution of plan, though admitting of improvement, is good. The museum occupies the eastern side. The style is Gothic, and of not so expensive a kind as one which seems to have gained most favour. The front façade is rather heavily treated, though the gables of hall windows slightly breaking into the high-pitched roof are pleasing. We cannot admire the squat manner in which the side tower is terminated. No. 25, "Utile Dulce;" the plan or this design appears to have elicited some local commendation no less than its exterior treatment. Confining ourselves chiefly to the arrangement, there is an irregular and scattered disposition of parts which rather detracts from some good points internally. The hall is placed on the west side of a central corridor running nearly its whole length, and is approached partly by it, and also from the end. Ample means of egress are provided—a very desirable point—but we think the lateral corridor has some disadvantages. It prevents the hall being lighted on the corridor side, and its great length is architecturally a mistake, as it appears too lengthy and wasteful of space for the purpose it serves. The walls struck us as being very slim for the size of such a hall, and we hardly think the lighting confined to one side will be very satisfactory. The museum is located along the principal front, and occupies the upper floor. It is entirely lighted from a longitudinal flat skylight along the front roof, which might have been supplemented by side lights along the upper part of façade, which is now usurped by useless and unmeaning areading. The style adopted by the author is Gothic of the English school, and the detail seems to be well studied. There is, however, a superfluity of costly elaboration lavished on the front elevation, and much useless and expensive ornamentation in the shape of angle turrets and other excrescences of doubtful character. The principal objection we have to the exterior is the jumbled way in which the upper portion of the central tower is notched into the roof and springs from the lower portion of tower, the attempt at originality here being particularly awkward and whimsical, so much so as to seriously mar the effect. The cost of this design, moreover, will, in our opinion, be sufficient to set it aside.

No. 26, "Manners makyth Man," has a very compact plan. This plan covers less area than any other design exhibited. The hall on the ground-floor is rather long, and the entrance, limited to one in the centre of its longest side, is too limited. The walls are excessively massive and contrast rather strangely with those of other plans. We think the author has not given sufficient space to his approaches and stairs. In other respects there seems to be careful study evinced. Externally this design is shown by a well-drawn outline perspective, evincing the hand of an artist. The design, however, has more of a fortress character about it than that of a building destined for civic uses, the centre tower being overpowering in its mass and height, and the grouping and severity of the masses generally are rather more picturesque than architecturally appropriate. Although not quite so much condensed in superficial area as the last, "Concentration," No. 27, has a remarkably compact and well thought-out arrangement. Forming a rectangular block, there is perhaps less lost room in this plan than any others. The hall is located along the back, and is amply approached by entrances at the east and north sides, though rather indirectly. The only fault seems to us to be the number of exterior steps required to gain the principal apartments, though it must be remembered an excavated basement on the intended low site for this building would be very questionable; probably the author had this in view. The conveniences of this plan appear to be more complete than any of the others. The proportions of hall and its roof are good, and the arrangement of the whole plan is, as we have said before, well considered, and fully bears out the motto adopted by its author. The external front of this design, which is in the Gothic style, has, perhaps, a somewhat commonplace appearance, but its defects in this respect, which are chiefly those of detail, are quite overbalanced by the merits of the plan and its general proportions. If the same amount of study had been bestowed upon the façade which the plan evinces, this would probably have been the most successful design of the whole collection. No. 38 (red star in circle) is a pretentious effort in the Italian style. The arrangement and proportions of this design are both wasteful in area and extravagant in the heights of assembly room and other portions. The author claims for his plan ample means of ingress and egress. He has truly outdone himself in this effort, for the area at disposal is completely squandered and intersected by ridiculously wide corridors crowding out all available lighting and air spaces. The superficial area covered by this plan is the largest of any. The Italian façade, shown by an effectively coloured drawing, with its extravagantly high and frittered centre tower, and the columnar wings of a commonplace type, broken cornice crowned by statues, is certainly ill-adapted for the Winchester site and surroundings, and far too costly. No. 46, "Faith," is illustrated by a carefully and elaborately got up set of drawings. The plan is hardly so well considered as some of those above noticed; the entrances are defective. The hall and council-chamber are cleverly managed as regards their roofing and lighting, while the style and treatment adopted is bold and effective. The vigorously-tinted perspectives display an effective tower and front towards the High-street, which contrasts rather favourably with many others exhibited. We think this design should have certainly displaced No. 38 in the committee's selection of the number recommended. There are a few other plans that deserve a passing notice, such as No. 2, "Perseverando," in which the arrangement is condensed and compact: No. 3, not a badly conceived plan in general, but in a very heavy Gothic style of treatment, with a tower cumbrous and unrelieved. The same author's Italian design is better. No. 9, "Alpha," has a plan capable of improvement, the corridors being too wide. The style is Gothic, and the front is relieved by an arcade open to the street, and generally this design is characteristic of the purpose of a town-hall. 13, "Caer Gwent," has a plan on a good principle, but not so happily developed; 14, "Justitia," has a well-considered plan; 16, "Rufus," has a miserable plan in the Tudor-Gothic style; 11, "Civis," has a badly-arranged and patchy plan, with a preposterously high tower. The drawings, however, are elaborate and striking.

The adaptation of style to site is a question of some importance in the selection of a design, and should be taken into account after the plan. The Winchester Corporation have selected a site which demands the exercise of some judgment and taste. Fronting the widest, flattest, and most open part of their picturesque and declivitous High-street, it is of primary consideration what character of structure would best harmonise with the adjacent buildings and scenery. We say "harmonise" in a relative and local, not absolute sense. Essentially of an irregular and picturesque kind, it becomes a problem of some difficulty to the architect whether a style partaking of rectangular masses and horizontal lines would contrast favourably with a situation so sudden in its abrupt lines. It is true the particular site is a flat one, but the objects in proximity are of a character that we think require some degree of assimilation in the style of the town-hall. We think on the whole a Gothic treatment the best, and those designs which con-

form to the continental Hotel de Ville type of structure, having a prominent and well emphasised tower, either in the centre or at the side, seem to us to adapt themselves most favourably. Ere this notice is in the hands of our readers, the selection of a design for this town-hall will have been determined, and we hope satisfactorily and with the guidance of a qualified judge. There are many other designs which we noted, but of which our space forbids notice here—some artistically conceived, as Nos. 18, 19, &c., but failing in essential points of design; while some others, as Nos. 20, 21, 29 and 45, would have contributed more to the credit of the competition by their absence.

[For telegram stating the result of this competition see p. 79.]

BUILDING NEWS SKETCH BOOK.

SEDILIA AND PISCINA, ST. PETER'S, PRESTON, SUSSEX.

THE sketch is taken from an interesting little church at Preston, Sussex, situated about one mile north of Brighton. The Sedilia and Piscina are in a very good state of preservation; the style is Early English (about 1230.) On the east wall of the nave, on either side of the chancel arch, were discovered, not long since, some frescoes, representing the murder of Thomas-à-Becket, and S. Michael weighing the souls of the departed, and are remarkable for the freshness of colour, and give a good idea of the state of art at this period. The church, fortunately, has undergone no alteration whatever.

GEORGE HOLFORD.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

LECTURE XIV.

THE fourteenth lecture of this course was delivered on Tuesday week last. In commencing, Dr. Zerffi proceeded to enumerate various examples of construction in the different styles he had mentioned in his previous lecture. Commencing with the oldest, or Proto-Doric style, he alluded to Stella and Hermes, in which the first attempts to construct Doric columns could be traced. The contractura in these columns was towards the base. There also existed façades of rock-hewn cellas or graves, of which those of Nouchia in Etruria and a rock-hewn grave at Nikoleia in Phrygia, were notable examples. In these constructions stiffness and austerity of form were the prominent characteristics. The columns were in some instances fluted, in others smooth, and the shafts marked with one or three rings. The oldest of temples, that at Cardacchio in Corfu, which might almost with equal justice be assumed to have been merely the cover of a well, was nearly proto-Doric in form. The pillars were slender and gently tapered, the capital strong, the echinus projecting, and the neck decorated. The distance between the columns was great. The frieze was without triglyphs, the pediment very high, and the fluting of the columns very flat. These were all the structures that could be traced prior to the seventh century B.C., when we had the Lax Archaic Doric style, of which the temples of Assos, in Asia Minor, and the Tavola dei Palladini, at Metapont, were examples. This style differed from the Proto-Doric, inasmuch as the distance between the columns was less, the columns themselves were shorter but more tapering, and the echinus boldly protruded. There were three incisions at the neck of the column. In the older constructions in this style the entablature was more than half as high as the columns supporting it, and the columns had twenty flutes; in the later forms the entablature was a little less than half the column, which had sixteen flutes only. The kymatium, or cyma, was round, but lighter than the Proto-Doric. The temple of Demeter, at Pæstum, might well be considered as belonging to this period, were it not for the fact that the columns were so closely set. In the Stern Archaic Doric style (seventh and sixth centuries B.C.) were the temples of Selinus and Ægina. Though, as far as the architecture of these two buildings was concerned, we might assume them to have belonged to the same period, they widely differed in their sculptural ornamentation. In the former temple the facial expression of the statues, the Asiatic fashion of the hair and beard, together with the conventional treatment of the drapery, led to the conclusion that it had been contemporary with the Monuments of the Harpies. In the latter, however, later influences could be traced. The special characteristics of this style were stiff outer columns, a high and strongly protruding abacus, which was one-sixth broader than the intercolumniation, a stiff and flat echinus, scotia, and rings below finishing the flutings of the shaft. The columns of the pronaos had sixteen Ionic flutings. The tapering was very considerable, being ·685 of the lower part, and the tapering in the interior columns was still greater. The marvellous temple at Ephesus (which the lecturer fully described in his former course of lectures) influenced the Greek artists, and stimulated them to greater exertions. The temples of Artemis at Syracuse, and that at Corinth, might be looked upon as attempts to rival that construction. Their dimensions were colossal, and though the old proportions were observed, the intercolumniation was as narrow as possible. The height of the entablatures was half that of the columns. The ruins of the temple of Corinth were generally accepted as being the most ancient remains of Doric architecture. The finished details and the treble incisions under the capital would, however, have justified archæologists in placing this building in the period in which the temple of Ægina was constructed. At the same time, these two temples presented examples of the transition to the Pure Doric style (fifth century B.C.). As examples of this style we had thirteen temples—viz., those of Zeus at Selinus; of Heracles at Agrigentum; of Zeus at Agrigentum; of Poseidon at Pæstum; of Athene at Syracuse; of Juno Lacinia, at Agrigentum; of Concordia at Agrigentum; the temple at Segesta; the southern temple on the western hill at Selinus; the southern temple on the eastern hill at Selinus; the temple on the Island of Ægina; that of Zeus at Olympia; and the temple at Bassæ. Having mentioned the chief characteristics of these buildings, the lecturer passed on to the Attic-Doric or Periclean style (fifth century B.C.) He said that in this style we found the spiritualisation of Doric power and typical regulation united with Ionic grace and individual expression. The old Doric might be distinguished as the sandstone or limestone style, and the Attic-Doric as the marble style. The treatment of the forms differed with the material. Those in marble were more elegant, the columns lighter, and the ornamentation more refined and profuse. Amongst the temples in this style were those of Theseus at Rhamnus, the Parthenon, &c. Even prior to the period of the Macedonian Doric style (four centuries B.C.), the Doric style ceased to be employed exclusively for temples, and was also used for profane buildings. At first the Ionic and subsequently the Corinthian order became more prevalent, in accordance with the increased refinement of the people.

The Ionic order was slender and beautiful, and was undoubtedly perfected by Greek taste. Dr. Zerffi here entered in detail into the characteristics of the three styles into which he had divided the Ionic order; and having dwelt at some length on the Corinthian order and its styles, he proceeded to the consideration of the ceramic art of the Greeks. He said that in speaking of prehistoric pottery in former lectures, he had referred to the principal styles. After form, strength and durability of material was the most important desideratum. This might be attained in three ways: (1) by simply drying the pottery in the open air, or in the sun; (2) by exposing it to a gentle heat; and (3) by exposing it to a more intense heat. The method of glazing pottery, he observed, appeared to have been altogether unknown to the Greeks; at any rate, it was not used by them, and hence the earthern vessels of ancient times were not entirely impervious to water. On the other hand, there were advantages connected with these porous vessels which had been subjected to a gentle heat only, as they resisted sudden changes of temperature better, and did not break so easily as those which had been more thoroughly baked. In making pottery which would be subjected to the action of intense heat, an entirely different treatment was required. The plastic forms should be well chosen, and such as might suffer through baking should be avoided. Metal or bronze motives, Telamons, &c., should not be imitated in ceramic works, for in such cases the material would be employed for a purpose for which it was not at all adapted. The style of the ceramic artist should be dependent on the three principal properties of the material used, viz., plasticity, homogeneity, and capacity for hardening. Ceramic art, said the lecturer, had developed itself to a certain extent in analogy with the geological formation of the earth, but in an inverted ratio. The oldest pottery (prehistoric) was coarse, and its material was provided by the latest formation of the earth, *i.e.*, the soil itself. Chinese ceramic pottery, however, formed an exception to this, as the Chinese people had used kaolin, which was of the primary formation. The productions of the mediæval potters, such as faïence, were made of materials obtained from the secondary formation of the earth's crust; and for the last three centuries we had made our ceramic works of materials found in the oldest formation. The oldest specimens of pottery much resembled each other, and it was difficult to distinguish the productions of Kelt, Teuton, Scandinavian, Greek and Italian, from one another. In such productions as assumed the trochoid form, there was evident a plastic tendency to strengthen the wave-like forms by additional ornamentation. This ornamentation consisted in geometrical figures, knobs, astragals, and guilloches. The Greeks highly improved upon this rude pottery. Their style and execution presented the greatest contrast to the productions of other nations. The lines were more defined, and the symmetry more perfect. The ceramic art of the Greeks flourished most successfully at Samos, and in other islands of the Archipelago. Its most striking characteristic was at that time that it ignored the use of the wheel. In other countries, where the wheel had been used from time immemorial, we should find that it had had a detrimental rather than an improving effect. In conclusion, Dr. Zerffi said he divided Greek pottery into two classes—the oligochromatic (from ὀλιγος, small, and χρωμα, colour), and the polychromatic. The first of these he subdivided into two sections:—(1), the Archaic; and (2), the Hellenic. He also remarked on the fact that the greatest Grecian sculptors had modelled designs for ceramic works, and had even practised the art themselves.

LECTURE XV.

Dr. Zerffi delivered the fifteenth lecture of the course on Friday afternoon last. In this lecture he concluded the subject of Greek ceramic art, which was left unfinished in the last lecture. After recapitulating the principal points respecting Greek ceramic art referred to in the preceding lecture, the lecturer drew attention to the evident traces of manipulation in some of the specimens before the audience. The introduction of the wheel and of glaze, which had taken place at a later period, necessitated the preparation of a firmer paste. This paste had to be subjected to great heat, in order to enable the artist to produce a greater variety of vessels. The transition from rude to improved works had taken place slowly and by degrees; in the beginning the paste had been coarse-grained, the ground colour yellowish-grey, but subsequently it became fine and the ground colour homogeneous. The glazing had been altogether dead. The black colour (not pure, but with a brownish tint), had been spotted, proving a want of experience in baking. In addition to the black glaze, violet, brownish-red, and white tints had been applied, but they had been badly fixed on the paste. With the exception of the pethoi (or wine jars) found at Thera, the vessels of the Archaic style were generally of moderate size. They were broad, compressed, the curves boldly interrupted, and the extremities abruptly connected. The ornament did not form, as yet, an integral part of the vessel. The general forms were pots, cups, flasks, &c., the oldest having been ornamented with points and simple lines drawn all over the vessel. At a later period the ornamentation had been restricted to the bulge, whilst rings, frets, or meanders had marked the upper or lower parts. Plant forms had then been introduced in ornamentation. A further progress was to be observed in the use of animal forms, which surrounded the vessel in parallel circles. In addition to animals and monstrous Asiatic combinations, human figures were also used. In studying these ornamentations a clear progressive development in the whole culture of the Greeks could be perceived. The Hellenic or pure Greek style comprised all the later productions of oligochromatic pottery. It essentially resembled the Archaic style, but possessed a greatly improved ornamentation. The paste was harder and firmer, the colour softer, and the best clay was employed. The black had a greenish lustre, and was without spots. Smoothness and elegance of form, and delicacy in the decorative ornamentation, render this style most interesting. The figures were no longer cut in with the needle, but were laid on with the brush with great accuracy. The frame

usually employed was dispensed with. This was an advantage, as it gave greater scope to a more connected ornamentation. In examining the general features of the Greek pottery of this period, we found that it was in many instances not so perfect in point of detail as in the total. The productions were the result of the freest, most conscious, and most accomplished mastery of all the conditions inherent in the material employed, and in the purpose of the product. In the first, or Archaic, period, the artist appeared to be struggling with his material, but in the second, or Hellenic, period we found him master of it. The curves became less bulky, and the transition from concave to convex lines less abrupt. Though a tendency to over-ornamentation was still to be observed, it was checked by an improved taste. A regularity in decoration was next to be perceived, more especially during the period from the Pisistratides to the Persian wars. All the productions of this epoch had been thoroughly correct, but rather stiff. That the vessel should form in all its parts one continuous line, with as little interruption as possible, became a law. The influence of the Doric-Ionic or Attic style, however, corrected this stiffness, and Greek ceramic art reached the very acme of its development. The decorative motives were in accordance with the gradual progress. The Asiatic types of monsters were used as frieze ornaments, and soon gave place to garlands, frets, or to useful domesticated animals. The creations of over-heated imaginations were replaced by heroes, such as Perseus, Theseus, Heracles, &c., always representing the triumph of valour, beauty, and honesty, over barbaric licentiousness, dishonesty, and despotism. There remained now only the polychromatic style to be described to conclude the subject of Greek ceramic art. This style had originated in a direct line from the first attempts in the art, when white pipe-clay had been painted over. The most celebrated specimen of the style was the vase of Arkesilas. The colours employed were prepared from red, violet, and yellow oxides of iron. During the period which corresponded to the introduction of marble in architecture and ivory in sculpture, we found these highly-coloured and richly-decorated vases. The paste was fine and originally white, and the colouring encaustic. It appeared that not only mineral pigments and metallic oxides, but also other colours could be fixed on the thin paste, requiring only a slow fire. Greek pottery was one of the most important aids to the study of Greek social customs, fashions, and even manners. The pottery, as Dr. Zerffi had previously stated, embraced no less than seven centuries of national development. In examining carefully the various representations on the different vases, we might trace two distinct fashions among the Greeks—the Doric and the Ionic. Simplicity, sternness, and austerity marked the Doric; whilst elegance, taste, refinement, and symmetrical ornamentation characterised the Ionic. Subsequently the Attic-Ionic had been developed, joining the two fashions into one of the very highest artistic perfection. After the age of Pericles a kind of over-ornamentation prevailed, and with it degeneration, corruption, and dissolution set in, socially, politically, and artistically.

To enable us to understand Greek sculpture an acquaintance with the dress of the nation was necessary. Dress, with the Greeks, had two objects—to disguise and to reveal. A linen garment, oblong in shape, was used as underclothing, and a square woollen one as cloak, mantle, shawl, or coat. The linen was white, and the wool (especially with the Dorians) tinted yellowish or brown. At a later period both linen and woollen stuffs were dyed by the Ionians. With the Dorians the dresses for both sexes were alike, but those of the men were shorter and less ample. The principal garment was the cloak, which was generally thrown over the left shoulder, leaving the right arm free. Sometimes it was thrown over both shoulders, thus beautifully draping the bust. This cloak rarely reached below the knees. The linen under-garment was only sewn on one side. Sleeves were not used till Asiatic customs had been introduced. The under-garment for women was very long and fastened by a girdle and then drawn up, thus falling in beautiful folds round the waist. The cloak for women was identical in appearance with that of the men. The Attic-Ionic fashion preserved the same principles, but the women were more wrapped up, and the under garments of both sexes had sleeves. When at rest the hands were hidden, and in speaking the left arm only was used to give emphasis to the oration. Some general observations on Greek dress, as compared with the costumes of the present day, concluded the lecture, which was illustrated with numerous specimens from the magnificent ceramic collection of the museum.

LECTURE XVI.

The sixteenth lecture of the course was delivered on Tuesday afternoon last. The lecturer commenced by observing that he would continue the subject of Greek dress, and also describe some of the weapons, customs, &c., of the Greeks, in order to pave the way for the consideration of Greek sculpture. Both upper and under garments, he said, had been fastened at the shoulders with pins, buckles, or other ornaments, in the manufacture of which the Greeks had excelled. The stephane, a kind of diadem, had been considered the fittest head-dress for women. It was either a broad or narrow ring, pressed deeply on the brow, and had a broad ribbon which confined the hair at the back of the head. It was to be observed that with the Greeks a low forehead in women had been considered a beauty. Great attention was bestowed upon sandals, though boots were also known. They were made of the finest purple leather, and ornamented with embossed work in gold, silver, and other metals. At a later period the character of the sandals had changed, as they covered the upper as well as the lower portion of the foot, and so partook more of the nature of the shoes of our own times. Little boots were also in use, and the men ornamented their sandals, shoes, or boots with a half moon. This probably originated in a superstition that the emblem of Diana would protect the wearers from injury. With regard to the mantles of the Greeks, there had been differences of opinion amongst archæologists as to whether they had been square or round. Winckelmann, notably, had asserted that they had been round. Dr. Zerffi said he was inclined to think that both opinions were correct, as he believed the Greeks had had their fashions, which were subject to change. These cloaks had been provided with tassels which were filled with lead, and thus served to make the drapery hang in elegant folds. In many instances the women had an upper dress over the under-garment in addition to the cloak. It was made of two square pieces, sewn together, and ornamented with frets, meanders, &c, but had no tassels. The girdle used by women was worn immediately below the bosom. The Amazons had formed an exception to this rule, as they had worn it round the waist, like men. Venus alone was provided with two zones or girdles, and these were shown in the beautifully-draped Venus which had been in the Palace Spada, and afterwards in the possession of Lord Egremont. The lower girdle (also called the girdle of Venus) was distinctive of the goddess of love. The women wore veils, which must have been exceedingly fine in texture, as Homer had described them as cobwebs. Caps, which had been arranged in folds and fastened by a ribbon, had been worn by elderly women only. Straw hats, similar to those of the Italians of our days, were also worn. Men had their hats of felt, which were tied beneath the chin. The dresses of the men had, in general, been simple, but they paid great attention to their hair, which hung down in long ringlets. They also allowed their beards and mustachios to grow; the Spartans, however, had shaved the upper lip. The Argives alone had worn the hair short, after their defeat by the Spartans, and it was only with Alexander the Great that this fashion, together with that of shaving all hair from the face, had become general. The women were accustomed to dress their hair very simply. It was rarely or never cut, except in the case of widows, and children who had lost their fathers, and was generally confined in a net. Rings were worn on the third finger of the left hand, and had been of iron with the Spartans, and of gold and precious stones with the Ionians. The cane was also an ornament with the Greeks, and had been simple or adorned with an embossed knob. Earrings were worn by women, and sometimes (though rarely) by men; the Achilles in the library of the Vatican had them. Bracelets were in fashion on the upper and lower parts of the arm and above the ankles; they were generally in the form of serpents or of twisted bands. When the Greeks degenerated they had worn silk under-garments, and upper-garments of purple wool and often of gold-stuff. The weaving of gold with other materials had been introduced by Attalus. The lecturer next proceeded to enumerate the colours peculiar to the different gods and goddesses, and went on to say that the Greeks had uncovered their heads when meeting acquaintances or superiors in the streets. He also described the Phrygian cap, and said gloves had been in use, as several figures on burial urns might be seen with them in their hands. Passing on to notice the accoutrements of the Greeks, he said that these had consisted of the helmet, the breast-plate or cuirass, and greaves. The breast-plate was either of linen or of metal. Those of linen were prepared by soaking the material in strong wine or vinegar, and then folding it eight or ten times; they were put on whilst still wet, and thus took the form of the body, showing the muscles in a very perfect manner. The breast-plates of metal were beautifully embossed. The helmets were not only of metal, but also of softer materials. This could be seen in a statue of a hero with a helmet crushed under his foot at the Palace Farnesi. This helmet had most probably been of leather or felt. The greaves had differed but slightly from those worn throughout the Middle Ages. They were of thin bronze, and ornamented with lions' heads at the knee. Their principal object was the protection of the shin-bone. The lecturer concluded by describing the weapons used by the Greeks. These had consisted of the spear, which varied in length from 5ft. to 8ft.; the two-edged sword, the blade of which had been first of flint, then of bronze, and finally of iron; and the shield, which was richly ornamented. The sword had the simple form of a cross. The club was not used after the time of Pisistratus. The archers and slingers were generally slaves, it having been thought to be beneath the dignity of a Greek to fight unless in a hand-to-hand encounter. Horsemen (who were but few in number) had been armed with spears from 8ft. to 9ft. in length, and with long swords. The geographical position of the country, which always influenced military organisation, did not render mounted soldiers necessary, and it was only after the retreat of the ten thousand under Xenophon (in the fourth century B.C.) that cavalry had been generally introduced.

Greek furniture and the first principles of sculpture will form the subjects of the next lecture.

ARCHITECTURAL ASSOCIATION.

AT the usual fortnightly meeting on Friday evening last, Mr. Rowland Plumbe, F.R.I.B.A., Vice-President, in the chair, Messrs. C. J. D. Guy and E. M. Forster were elected members. Mr. J. S. Quilter, hon. sec., having made several announcements, which will be found in the first paragraph of "Our Office Table" in this week's BUILDING NEWS,

Mr. T. ROGER SMITH, F.R.I.B.A., read the following paper

ON LONDON AS A FIELD FOR ARCHITECTURAL STUDY.

London is not—and it is as well to avow it from the first—a favourable field for architectural study. It is so very mixed: it includes so much that is devoid of all character, so little (comparatively speaking) that can rank as architecture. London is, moreover, so very vast, so bewildering, and so perplexing in its extent, that it is difficult to concentrate the attention, and to select or to grasp any instructive group or series of buildings; and, worst of all, to those of us who live and work here, London is so familiar, and to many of us so distasteful, that it appears difficult to see how any lesson can be obtainable out of it, or, at any rate, any lesson we may learn with pleasure. It is no doubt easier by far for a student of architecture to learn his art from single buildings, or from striking towns and cities visited for the express purpose of study, than to pick out from the vast mass of heterogeneous materials which compose a city like London those which shall be serviceable to him. If it were a question of choosing what city of all Europe or all England I should recommend to you as the most likely to be useful to the searcher after striking architectural examples, such as none of us could well miss or easily mistake, I do not think London (notwithstanding all I may have to say in its favour) is the place I should name as likely to be advantageous, except possibly to those whom a great deal of previous experience and travel has fitted for the mature study of the mixed field which the English metropolis presents, and who know well how to winnow out the wheat from the chaff. But the imaginary case of suggesting a place to go to is not the actual one. Here we are, all or very nearly all of us anchored here, working in London and living in or round London. The museums libraries, galleries, public lectures, streets, squares churches, clubs, and mansions of London are about us, and are the only advantages open to many of us and whether we choose it or no, some of them are every day exercising some sort of influence upon our taste and our practice as students and prac-

titioners of architecture; while the compact and striking series of examples which our cathedral towns or the cities of the Continent afford us are only reachable to many once or twice a year for a brief period, and not always that. Do not let me be misunderstood, however. Nothing that I am going to say should be taken as meaning that an architect can be educated without travelling, especially if he be a man of ordinary stuff. I hold it to be essential to our fit training that we should travel and sketch—aye, and that we should keep up the habit of travelling and sketching, just as it is essential for a surgeon to dissect or for a barrister to attend the courts. But still there is so much, so very much, which might be learned (even by a young student) in London; and it occurs so seldom that any one appears to profit as he might by studying London, that I have desired to point out to those who are rooted to this city for the greater part of the year that there is more good material for study within their reach (though not always *easily* within reach) than could be thoroughly exhausted even by years of study. It has seemed to me additionally worth while to attempt this, because, as I have said already, London is, in fact, influencing us in some way. If we are in the habit of glancing carelessly at its fine buildings without admiring them, or are familiarizing ourselves with its bad buildings without disapproving of them, we are blunting our perceptive faculties and doing ourselves harm, or, at the best, are missing opportunities of gaining good, instead of turning them to account and making the best of our surroundings.

It appears to me that an architect seeking to begin to learn something from the examples round him in this city is very much in the position of a person introduced for the first time to some magnificent library, such, for example, as that of the British Museum. The more previous knowledge he has the better use he can make of what he sees. A ripe scholar, anxious for information on certain points, will know the names of the authors he wants to consult, will find speedily whether they are on the shelves or no, and will be at home in the library in a few minutes. Such an one does not need to trouble the librarian greatly, and, in the same way, a man who knows architecture well, who has seen many cities and studied many books, will not require that any one should point out the lions of London, or even the lions' whelps, to him. Those, however, who are circumstanced as (I think I may safely say) the majority of the members of the Architectural Association are—that is to say, who are in the early years of their study of a very wide and complicated art—may bear with a hint or two, and when they can find a guide (one far more efficient than the present speaker can be, especially in this brief paper), would do well often to consult him, just as a novice entering upon the use of such a library as I have supposed would do well to get a literary friend to tell him what are the books he ought to make most use of.

An architect's business is to build, substantially, suitably, and artistically, and he requires, accordingly, to learn how to construct, how to arrange, and how to design. Of these three things, arrangement is more easily learned and practised on paper than the other two, and the practice of a good office will go a long way towards enabling a clever man to learn how to manage a plan conveniently. The case differs, however, with construction and design, and it is on the scaffold that construction is best learned, and by means of the sketchbook that the materials, and, to a great extent, the methods of design, are obtained. It is chiefly, almost wholly, this last division of our studies that will occupy us to-night, for the advantages in the shape of buildings in progress which London constantly offers to students of construction are too obvious for me to need to enlarge upon them at any great length. What a student will find in London to assist him in learning to design (exclusive, of course, of books, classes, lectures, and office routine, which are beyond my present subject) may be said to include (1) examples of good buildings to study, mixed buildings to criticise, bad buildings to avoid—these last, unfortunately, in great plenty—and (2) objects of art, or architectural specimens, fit either to improve his taste or to increase his knowledge of the features of buildings or of decorative art. I purpose to consider museums first and then buildings, both, as far as possible, in chronological order—usually the most convenient arrangement of architectural matters—and we shall consequently inquire what ancient examples, what Mediæval ones, and (to some extent) what modern ones are to be found in London.

Of ancient architecture (if we mean thereby the actual buildings of the Egyptians, Greeks, and Romans), there is none, saving a few Roman pavements, the best of which is that found in Leadenhall-street in excavating for the foundations of the late India House. Of specimens of the art of those nations, features and decorations of their architecture, and reproductions of their buildings, there is a wonderful amount in London. The monuments of Egypt present to us the most remarkable examples possible of grandiose simplicity; they are remarkable for the graceful beauty of single features and for their skilfully-applied surface decoration, and they are still more remarkable for their conventional treatment of statues intended to combine with or form part of buildings. You will find at the British Museum, and Sir John Soane's Museum, many specimens of the statues I refer to, in which the pose is thoroughly symmetrical and stiff, and most of the anatomy is only hinted at or indicated in what is termed a conventional manner. I believe that it would well repay a student's trouble if he were to examine *all* the statues, and to draw one or two of them carefully. The use made of these statues, the surface-decorations, and some of the varieties of capital, are all to be seen well illustrated in that neglected but magnificent architectural museum, the Crystal Palace. I shall have again and again to refer to this collection, and may therefore say here, once for all, that it is, I believe, quite the finest in Europe, yet so much over-looked that I never saw a student drawing there in my life except myself; but, as far as my own experience goes, no difficulty will be thrown in the way of any student desirous of studying there. At the Egyptian Court of the Crystal Palace, I would advise you to try and form some idea of the value of the repetition at regular intervals of the same ornament; of the powder of broad vast masses, as shown in the façade imitated there; and of the grace of the capitals and colouring. These last might be well sketched there, though, as far as concerns matters which can be studied elsewhere, I may as well recommend you as far as possible to draw at the Architectural Museum, as a more studious place. No doubt all this is imperfect and fragmentary knowledge, but it is a most valuable addition to what can be got from books or lectures; and a resolute, energetic student, desirous of making himself familiar with those points of Egyptian art which are likely to be of value in forming his taste and guiding him in practice—not, of course, teaching him to do buildings in the Egyptian style, but to introduce into the work he does in a modern style those qualities in which Egyptian buildings excel—will find material enough within reach. To such a one I especially commend the conventionalised statues. Passing by the Assyrian art, of which fragments having the deepest interest to the antiquary abound in London, we come to those specimens of Greek art which London can offer; and here I need hardly tell you the national collection and the Crystal Palace vie with each other in affording the student an opportunity of study of the most remarkable description. You can see not merely casts, but the actual sculptures themselves, which were the most perfect work of the most consummate artists the world ever saw, and you can in their vases see specimens of the perfection of refined form and of subtle surface decoration. My impression is that stay-at-home travellers will do well to concentrate such attention as they can bestow upon Greek art upon the sculpture and carving, for the simple reason that, in this climate, and with stone to build in, it is simply impossible to emulate and almost even to understand the beauty of so subtle a thing as a Greek building erected in marble, seen under the bluest skies, through the clearest atmosphere, and lighted up by the blaze of a vertical sun. It seems to me that all the attempts we have made to introduce Greek architecture have failed, just as attempts to grow an exotic plant out of doors must fail; and if I except the very clever designs of the Messrs. Thompson, of Glasgow, it is on the faith of drawings only, and from a conviction that they have worked in the spirit but not at all by the methods of the Greek architects. Greek art was succeeded by Roman, and all the architecture of Europe, and possibly much of that of the Mohammedan world, can be traced by direct lineal descent to that original; and inasmuch as the actual structural work, the architecture proper, bears a larger proportion to the whole mass of Roman art than it does to the art of the Greeks or Egyptians, there is more difficulty in your learning what you want to know about it from museums alone. On the other hand, the materials are not altogether wanting. The Crystal Palace once more supplies us with an example of the domestic architecture and the decorative painting of the Romans in its Pompeian House, and displays also many specimens of sculpture; while objects of all kinds, such as lamps, bronze implements, chairs, mosaic pavements, may be examined and sketched by you in the other museums. An exercise useful in itself, and more so in its results upon the artistic instincts, is the effort to become familiar with the differences between Greek and Roman art. Compare Greek statues with Roman, Greek coins with Roman, and so on through the various classes of objects which you can obtain access to, and you will, in addition to interesting yourselves, gain at the same time an insight into the nature of works of art that will benefit you for life. Greece and Rome, as you know, were succeeded by Byzantine and Ravenna as centres of artistic activity; and I must confess that I can point to little which will give you good ideas of the peculiarities of Byzantium architecture, though fragments of the sculpture and painting emanating from that school are to be found at South Kensington. The course of the round-arched architecture, which sprang from the Roman, and was modified in various ways in the earliest Christian centuries, eventually led it to our shores, and in the first actual buildings which we shall have to notice, we find London distinguished for at least one of the earliest and most perfect Romanesque buildings in Great Britain. Before, however, we come to existing buildings, I feel tempted, at the risk of interfering slightly with chronological accuracy, to conclude what I have to say about our museums. The style which, starting from Byzantium, ran east and south (just as the Romanesque ran west and north), and includes all Mohammedan architecture, cannot of course be studied from existing examples in any part of Northern Europe; but Mr. Owen Jones's skill and care have provided an admirable model of what may be taken as a good typical example of advanced Saracenic architecture in the graceful and elaborate Alhambra Courts at Sydenham. In Egypt and India a different development, simpler, grander, and more like Gothic, is found; but this specimen will enable the student to form some idea of the general characteristics of Mohammedan art. In all that relates to decoration, either coloured or simply surface-enrichment, the instinct of Eastern nations has been far in advance of ours, and no opportunity should be lost of inspecting Egyptian, Indian, Persian, Chinese, and Japanese work. Their sculpture, their carving, their inlays, their enamels, their woven fabrics, everything they produce, is to the last degree instructive, and the store of such things in London is now very great. The India Museum, the South Kensington Museum, and the shop windows of Regent-street and Bond-street, the specimens to be seen at Christie's or other auction rooms, and the various specimens to be found in private hands, afford endless opportunities of learning what perfect decoration means.

From the time when Mediæval art began to take the shape in which it first appeared, we shall find that we get actual buildings in London, but we get, in addition, an enormous accumulation of information (from sources difficult of access) upon the detail of architecture in our museums. The Sydenham collection, though rich in Mediæval examples is, I think, less instructive than our own Museum, owing to the mode in which various fragments have been thrown together in its Mediæval Court. The student must there be constantly on his guard, or he will do himself more harm than good; but the Mediæval tombs of which there are casts can be studied at Sydenham without this drawback, and are very useful examples. I hope, however, that there is no one in this room who needs to be told that at the Architectural Museum in Bowling-street, the sculpture, the carving, and the architectural features of every period, from the dawn of the Middle Ages to their close, may be found illustrated by casts and actual specimens from every part of Europe. Every arrangement to facilitate study will be found there, and it is hardly possible for any collection of fragmentary details to offer more advantage to the student than this does. The South Kensington collection supplements this gallery of casts by a series of objects of which the variety and beauty are almost embarrassingly great. Sculpture, carving, inlays, stained glass, enamels, mosaics, coloured decorations, ironwork, brasswork, goldsmiths' work, and all the numberless branches of the arts, are here represented by actual specimens of great extent and possessing great charms. To these one may add the Meyrick collection of armour, that at the Tower of London, the miscellaneous collection in the Guildhall Museum, the manuscripts in the British Museum, the collections at Sir John Soane's Museum, and the earlier paintings in the National Gallery; and we seem well supplied with the means of studying the details of an art which, more than any other, seems to require of the artist who would pursue it a complete and intimate familiarity with detail.

The Renaissance period is perhaps even better represented in our art museums than any other. The architectural detail, the sculpture, and the coloured decoration of the sixteenth century, are wonderfully well reproduced at Sydenham, and the objects in the Renaissance Court and the Italian Court are put together with far more consistency than the Mediæval ones. A certain amount of Renaissance work is to be found in the Architectural Museum at Westminster, but it is to South Kensington and the two collections of armour just alluded to that the student must turn who wishes to find the best fragments of architecture, decoration, pottery, wood-carving, metal-work, and artistic work generally in which this period was so rich.

In leaving the topic of our museums and their specimens and casts, I should like to anticipate an objection which may be raised by some of you to the extensive range over which I have directed your glance. Some may possibly suppose that, as architects, all you need know about is the forms of the moulded and otherwise architectural features of a building, and something of the shape which its enrichment will take; that is to say, that if you can do the plans, elevations, and sections, with the

profiles of the mouldings, it is all that can possibly be expected of you. The carver will contribute the ornament, the metal-worker and stained glass manufacturer will design the finials and the windows, Minton's or Maw's people will do the paving, and why, therefore, need you understand these things, much more the enamels, mosaics, embroidery or goldsmith's work, which are to be found among the museum specimens that I have recommended to your study? Now to this I have only two things to say in reply, and they put the answer on the lowest ground. The first is that no work of art or skill is so painful a failure, generally speaking, as that where the artist goes to the extreme limit of what he has been trained to do. A man doing the best human powers are capable of with the means at his command, even if he fall short, often produces the very grandest of all possible results, such, for example, as Giotto's paintings, or the Early Romanesque sculptures; but a man who manifestly has only got to a certain point along a road on which by patient industry he or any other person of fair ability might have gone further is in an entirely different position, and he becomes very clumsy and unsatisfactory in his work as he approaches that limit, just like a badly taught young lady playing a pianoforte piece that is just as difficult as she can possibly get through. If, therefore, you limit your technical training to just the minimum of what you think you are likely to want you will never put forth all your strength without its becoming painfully obvious that you are with difficulty doing what many another man would easily do, and the quality of your work as it approaches the limit of what you know will be inferior. The second answer is that though it may often be legitimate to leave a large part of the detailed design of detached parts of the work to the executing artificer, the artist who directs it all—the architect, that is—should understand the whole, should know how to subordinate each part to the effect of the whole, should be able to see at once what is wrong when any feature seems out of keeping, and should actually, in most cases, give the general design, and in some the minutely-detailed design, of those parts. But beyond this I hold that an architect's education ought to include familiarity with all that is ancillary to his own art. There is no decoration, no fabric, no art work, which may not be helpful to him, and which may not teach him something if fairly and honestly studied. The study must, however, be genuine study, not idle gazing, for let me remark, in leaving the subject of museums, that there is all the difference in the world between studying and staring. To use a large collection well, especially one so devoid of systematic arrangement as that at Kensington, a man must have a degree of method and concentration in his own mind, and must resist with energy the very strong temptation to become desultory, and loose, and lounging in his visits, which an attractive and extensive museum always exerts. To know one thing well is better than to know twenty superficially, and if out of twenty objects of art, all somewhat connected together, you select one, examine it, draw it, make a written description of it, and so master the details of its construction and design, it is all but certain that the other nineteen will very readily yield up to you an amount of information which, but for your careful study of the twentieth, you could not possibly have obtained from them. Of course in visiting a museum it is natural to spend a little time in walking round to see what is to be found there, but I am sure that it is most desirable to get to work *early*. If an object strikes you as supplying information you require, or as very beautiful, or very remarkable, in short, if it tempts you to study it, my advice would be—Out with the memorandum book at once; sketch away and make your notes before going farther, and you will, I think, rarely indeed find reason to regret your doing so. And though I have gone historically through several great periods, I do not mean thereby to insist on its being advisable to form a rigid course and follow it. If circumstances (say the buildings in hand at the office where you are articled), or the accidents of your own locality, direct your attention to any one style or period, follow it up, and in doing so try to recollect that it has its place in the great chain of events, and that you will have to supply other links by degrees. A course of reading, or, better still, a course of lectures, will make it desirable for you to be able to verify the history of architecture by a series of visits to the specimens I have pointed out to you, and under such circumstances they may with great advantage be used as a comprehensive series; but where there is not a great deal of leisure—where a student has, to a great extent, to construct his own method of study, and when a large chronological system seems formidable, chilling, and dull, my advice would be to plunge in at the nearest point, and to work away, penetrated with the conviction that a thorough knowledge of a comparatively small number of good examples, even if chosen almost at random, is a very good beginning indeed, and far more valuable than a fair superficial acquaintance with many periods of art without any intimate familiarity with any one.

We will now turn our attention to the actual buildings available, and for that purpose shall have to turn back to about the date of the Norman Conquest, or of Roman London. No actual structures of this date exist that are much worth naming to you, though we have some few specimens of good pavings. Of Mediæval architecture we have sufficient specimens standing to render London a fair field of study, if not a rich one, and if those places be included which can be reached with a little expenditure of time and money by rail, there is a very large series of examples to which the student's attention may be turned. The best among the early specimens of Christian architecture in London, and one of the best in England, is the chapel in the Tower. This very early round-arched example is in the best possible preservation. It is invaluable as an archæological example, and it is quite as good as a specimen of simple church architecture. It would not absorb a great deal of time if a student were to measure and draw the whole of it, every detail included, but I think the time would be well spent, especially as he would get a familiarity with two features that are rare in England—an apsidal east end and a vaulted gallery or tribune, an essential part of the early basilicas, but not common, except in the shrunken form of a triforium, in this country. Of round-arched architecture there are some interesting but scanty remains at Westminster Abbey, and though they will speak more plainly to him who has seen a good deal of the same sort of work than to an untravelled student, they ought to be visited. As specimens of what remains within reach of London I may just name S. Alban's, Rochester, and Waltham Abbey. A splendid example of Transitional work exists in S. Bartholomew's Church, Smithfield, restored with great care by Professor Lewis; and an equally good example, of a little later date, exists in the Lady Chapel of S. Saviour's, Southwark, a building of the utmost grace and beauty of design and detail. Almost every phase of Pointed architecture, from Transitional to Tudor, may be found and studied with the utmost advantage at Westminster Abbey. It is not too much, I think, to say that in the Abbey, with its cloisters and Chapter-house, we have a sufficient model for the stay-at-home student to learn all that needs be learnt in order to be familiar with the main elements of Gothic architecture. It is true that in some cases there is not a complete series of examples of every sort of thing belonging to every period; but there is almost, if not quite, every feature of some period, and every period in some feature. The arcading, and caps, bases, and mouldings, including large and small, would, I think, enable a quite perfect series to be made out of capitals, bases, and archmoulds. Nearly, if not quite, the same may be said of the vaulting, while of Late vaulting, one of the two finest examples known is Henry VII's. Chapel. Of tracery, avoiding what has been badly restored in former days, there is not so perfect a series, but still there are many varieties. The tombs, taken one after another, give a large series of tabernacle-work, sculptures, enamel, ironwork, bronze-casting and inlays. There are mural paintings in the Chapter-house and the Chapel of S. Blaise, and the ancient retabulum. There is magnificent sculpture in stone of every period, especially of the best, and there is a splendid example of Late sculpture in wood and tabernacle work in the stalls of Henry VII.'s Chapel; and last, but not least, there is the best tile paving now left entire in England in the Chapter House, and the best pavement in *opus Alexandrinum* on this side the Alps in front of the altar. In short (except, perhaps, stained glass), there is hardly a feature in a cathedral church which an architect cannot here find done, and well done, in some period of the Middle Ages. There is not a period, from the reign of the Confessor to the Reformation, which he cannot find more or less represented in the Abbey. If we pass from the study of detail to that larger study, at once more difficult and less cultivated in the present day—the study of general design—these four examples will be of the greatest possible value, as far as internal design goes. The Chapel in the Tower and S. Bartholomew's are, if I may be allowed the expression, insides that have no outsides; and S. Saviour's and the Abbey have had their outsides so marred by bad weather and bad architecture that it is not ways possible to get much good out of them; but it is not so with the interiors, and if the student will take some sketches and measurements in each example, in order to find out not only the nature of individual features but that of the buildings as wholes, he will be rewarded for his pains. You are no more a finished architect when you have only mastered detail than you are proficient in language when you know the vocabulary and some of the idioms. The genius of language, and that of architecture, uses, indeed, the correct materials, but in building them up into a whole it regards the beauty and fitness of the whole more than the propriety of the parts. There are a few more Gothic churches to be named, such as the chapel in Elyplace, the Dutch Church in Austin Friars, the Crypt of S. Stephen's Chapel in the Palace of Westminster, the Temple Church, the Chapel in the Savoy, and within easy reach, S. George's Chapel, Windsor, but they all suffer from the disadvantage of having been restored to an extent which more or less impairs their value as examples. Parts of the Temple Church, especially the western portion and its porch (comparatively recently laid bare) are of great value, however, and S. Stephen's Crypt is a good example of vaulting, and a good specimen also of lavishly-rich restoration.

Mediæval domestic work, like the Mediæval churches, must have disappeared wholesale in London at the time of the Fire, and it has been disappearing ever since. There still linger fragments and features which are precious to the antiquary, but I cannot recommend all of them as much worth the attention of the young architect in search of useful studies. The Tower, under good guidance, yields a certain amount of information, but almost every stone of it, except the chapel (already referred to), has been meddled with in some way, and, in fact, it is not till we approach Tudor times that available London examples are forthcoming. In Westminster Hall we have, however, one of the noblest specimens of secular architecture extant, in good preservation and in constant use, and it is as possible to get good from studying one secular example well as it is from one abbey. We can supplement Westminster Hall by Crosby Hall, the ruins of Eltham Palace, and the Gothic portions of Hampton Court, especially the hall, which is very fine. Lambeth Palace also contains sundry valuable fragments of various dates. If we now advance to that thoroughly English decadence or transition which gave so much that is picturesque—mixed, it is true, with much that is clumsy and uncouth—and to which we give the name of Elizabethan, we shall find a few examples scattered here and there, but not all of them easily available for the student. The Middle Temple Hall, parts of Holland House, the condemned Charterhouse buildings, are all that occur to me. But it London be poor in Elizabethan, there are excellent domestic secular architectural studies in the style, or earlier, within an easy run of London. Hatfield House is the best Elizabethan example on the north side, and, I think, the only one very easily reachable; but southwards a whole group are to be found all readily accessible by railway, and almost all open to the public, which, I believe, Hatfield is not. Near Sevenoaks we have Knowle, a fine and enormously large mansion, placed, like Hatfield, in a magnificent park, full of ancient furniture and plate, and, though not an imposing building, an instructive one. Not very far from this is Ightham Moat, and a few miles off are the moated house of Hever, Penshurst Place, and that most picturesque of all old-world villages, Chiddingstone. Indeed, scattered throughout the county of Kent there are many manors, farmhouses, and dwellings that it is most instructive to sketch and even to measure, if one desires to master the detail of late Mediæval and Transitional domestic work and the principles upon which those who designed that work in (an artistic manner (for it is by no means uniformly artistic) must have proceeded.

(To be continued.)

THE VALUE OF RUBBINGS IN THE PREPARATION OF MONUMENTAL DRAWINGS.

At a recent meeting of the Society of Antiquaries of Scotland, Captain T. P. White, R.E., read a paper "On the Value of Rubbings in the Preparation of Monumental Drawings." Passing on, after some introductory remarks, to consider the general question as to the value of rubbings, Captain White, referring to specimens of rubbed tracings exhibited on the walls, asked—Are not these tracings pictures in themselves, and must not drawings rigidly copied from them just as they stand retain to a large extent their veri similitude and pictorial character? It is this value, strengthened by an after-touching of the drawing on the ground, which I wish to compare with the value of unassisted freehand sketching. Let it first clearly be understood to what class of objects I refer in instituting this comparison. Any flat surface of a hard material—stone for example—with incised spaces carved on it, will give a paper-impression by means of rubbing with grass, kail, or other vegetable matter (better, I think, than with heel-ball or black composition). But it is essential that the carved work should be upon a flat ground, with simple hollows cut into it, in planes vertical to the upper surface. There must be no attempt to represent rounded forms by convexities or concavities. Everything pictorial must be restricted to outlines depending for their ornamental effect upon harmonious grouping, assisted by vertical relief, so as to form one flush surface. Now, these are precisely the conditions which obtain on flat tombstones, bare sculptured rocks, &c., but especially in the Mediæval slabs of this

class, and in monumental brasses. As an example of what I mean, look at the chalices on the drawings now shown. A real goblet, seen sideways, is of course round, yet on the stone it is represented by a flat surface—not a hemisphere—a profile outline, in fact, projected into a horizontal plane. An exception to this is met with in the effigies brought up into higher relief, and for that reason I do not consider such monuments fit subjects for rubbing. They fall properly within the domain of hand-sketching. Again, observe in all the slabs with ornamental foliage how every leaf is essentially a flat surface, with no other ornament but incised outlines. Knotwork, figures of animals, figures of men, sword handles, galleys, and so on—all are expressed by the chisel cutting perpendicularly down into the surface of the stone, and leaving a sharp edge. The only roundness, then, we need look for in these stones is in the edges of the incisures, which, after a lapse of time, will naturally get worn down, more or less according to the exposure. Another exception to this rule is in the headings, and to some extent in the larger figures of ecclesiastics cut in low relief. Sometimes—as was the case with a superb ornamental slab which my assistant, I believe, was the first to discover and trace for me—a stone is hidden away from exposure to weather and ill-usage, and thus the lines come out as fresh and sharp almost as if cut yesterday. The wonderful symmetry of the thread-like incisures, the faultlessness of every spiral sweep, speak for themselves in the rubbing. Conceive an artist refusing a perfect reduction from this slab to shade in, and setting to work instead to draw it freehand, in expectation of arriving at the same accuracy. The next question is this—Given a really good rubbing, carefully taken, what is likely to be its maximum faultiness, and from what causes? My answer is, that a good rubbing will be an almost perfect reprint of the stone, not merely giving all the outlines of the figuring in exact drawing, but reproducing every chip and crack in the upper surface of that figuring. It will be, in fact, like a life-size photograph—only often supplying much more than a photograph could do. Every little turn and twist, every minute deviation from uniformity in the pattern, every break in the edges, comes out clear and life-like; but always, of course, like the photographic negative, light in the hollows or shadowed portions, and dark on the upper surfaces. On the other hand, the worn roundness of edges, and any weather marks within the hollows, will escape the rubbing. But there is another property of the rubbing upon which I wish to lay particular stress, in contrast with what freehand drawing can attain to—this is, that in much obliterated slabs the rubbing will search out and record far more than the eye can possibly see on the slab *in situ*, at any stage of the sunlight—producing, so to speak, a resuscitation of what once was visible, but is so no longer. It was thus that the Saddell drawings showed more freshness of detail than is apparent on the ground. Often have I been struck with this peculiarity—this revivifying power in the rubbing. A notable instance is the ancient cross at Sanda Island. It will be seen what the rubbing shows, which has been reproduced in my drawing. I stayed two or three hours in the afternoon on the island, and saw the stone most of the time. Yet not the faintest indication of the various interlaced patterns, not even the divisions into panelling, except to a very slight extent, could be detected by the eye. I have here another fragment, on which one can make out a pattern of linked circles and beautiful underlying plaitwork that must have been very elaborate. Now, the surface of this stone is so unmarked to the eye that, after minutely examining it, and finding only a tiny hole here and there, I was obliged to rub it before I could decide if it was Mediæval or not. Could there be a more striking proof of this power of the rubbing? Or, again, look at this elegant slab at Saddell, one of those I formerly described as having on it a single sword, with surrounding tracery nearly defaced. The rubbing tells a different story, for it shows with a sufficient clearness the whole intention, character, and detail of the carving, almost as if we had seen it when freshly cut. In the drawing it is clear I must represent *more* than I saw on the stone, or else I shall be untrue to the life and spirit which, though hidden to the eye, still animate the sculpture. Rapidity of execution is another great point in favour of rubbings. Those three specimens I took myself in half an hour. How long would an artist be in doing justice to freehand drawings of them? Of course, my duties, which take me constantly through the localities where the rubbings were made, give great facilities for revisiting the ground and touching in the reduced copies. The next question is, how to utilise the rubbing for purposes of general illustration. Photography would only give negative transcripts, faithful enough of course, but according to my assistant, who tried it in one or two cases, not very satisfactory as pictures. Photographic prints would certainly be of considerable value if we could get nothing better, but then they would involve an expensive process. Still, what we should prefer to have is a positive pictorial representation as nearly a *facsimile* of the stone as possible. And this brings me to the concluding point in my observations. For, if I have established the high value of a good rubbing, and also of a photograph taken from it, that which shall substitute for the negative representation a positive one, with light and shade in their proper relative places, must surely be an advance upon either. So that, if a draughtsman sits down with a reduced pencilled copy of one of these rubbings, and simply effects the substitution I speak of, he must come a step nearer the end aimed at—namely, a perfect representation. Indeed, where the details of the rubbing are all obviously complete and intelligible, if he stopped there, and never revisited the ground at all, there would still undeniably be a drawing of a very high value to the historian, the archæologist, and the artist. Yet this is the precise position of the original Saddell drawings, the defects in them being entirely due to imperfections in the rubbings, caused principally by execrable weather at the time of taking them. The fact that those rubbings and the resulting drawings were slightly defective is used to build up the inference that all drawings "made up" from rubbings of "objects with a raised or irregular surface" must be entirely valueless. But I admit at once the desirability of touching up and perfecting the reduction on the spot. And when this is done, what unprejudiced person can doubt that the result must be a nearer approximation to the truth than the freehand work of the same draughtsman? Put into the hands of an artist the skeleton imprint or *facsimile* of that stone's sculptured surface for him to work upon, and you give him half the battle at once, and much more than half. Freehand drawing has its proper sphere, without undertaking too much. Glance at some of the more elaborate specimens of slab carving, and imagine what it would be to draw in by hand the multiplicity and extreme intricacy of detail here pictured! What would be the chances of getting into accurate position every touch and curve of a leaf or twist of a stem, or the endless ramifications of that running knot, or of that other interlaced wheel? Might not a crack be left out here, a chip there, and so on? Could every part of the carving be expected to appear in the unerringly true proportion given by the rubbing? Impossible, I say. You might set fifty draughtsmen opposite that rock sculpture to sketch it freehand, and not one of them would turn out the same drawing as any other. This, then, is the position I hope I have succeeded in establishing:—1st, that the monumental sculptured slab of the class generally found in the West Highlands is peculiarly suited for copying by the rubbing process; 2nd, that in point of outline accuracy such copies, and the drawings resulting therefrom, must more or less, according to the intricacy of the sculpture, surpass anything the freehand sketcher can attain to; 3rd, that in slabs much worn down, more detail oftentimes is caught and printed off in this way than is visible to the naked eye. And 4thly and lastly, that a mechanically-reduced pencil copy of such a rubbing, placed in the hands of a draughtsman, to touch in afterwards on the ground should, without sacrificing pictorial effect, be a more *scientifically* valuable illustration of the slab than a mere freehand sketch by the same draughtsman could be. But let me not be misunderstood. By "scientifically valuable" I mean valuable for the purposes of the historian and archæologist, that being undoubtedly the *primary* requirement. The *artistic* excellence of the drawings is for such purposes another but clearly a *secondary* matter. Were the point of issue one of pure art, the mechanism must at once be thrown aside. If we wanted simply a charmingly-executed picture and nothing else, then, of course, considerations of what constitute artistic merit proper would come uppermost, which would alter the case entirely. Personal skill, the individual mind of the artist, and such like qualities, would immediately affect the question. But it is just these personalities, or idiosyncracies, that we are not to recognise here—that, indeed, it is desirable to eliminate, except so far as they may serve in the capacity of handmaids to the strict object in view, that object being, I take it, to bring the nearest thing to the slab itself, with its collection of facts, before us on the paper. Yet by all means, having secured this first desideratum, superadd all the personal artistic embellishments in your power. And I see no reason, even from a pictorial point of view, why drawings fortified by rubbings may not reach, if not the highest, at all events a very high degree of excellence.

Building Intelligence.

CHURCHES AND CHAPELS.

BRISTOL.—The church of S. Nicholas, Bristol, was reopened for divine service on Sunday last. The old pews have been entirely replaced by seats of polished pine, with bench ends of oak. The chancel fittings have been taken away, and new fittings of oak erected, together with a new pulpit and priest's desk. The alterations have been carried out by Mr. W. Brock, of Temple Mead, under the direction of the architects, Messrs. Ponton & Gough. The total cost is about £600.

LEAMINGTON.—A vestry meeting was held in the Town-hall Leamington, on Monday, to take into consideration a report, presented by Messrs. Slater & Carpenter, respecting the condition of the parish church. On three several occasions portions of the stonework have fallen from the central arch into the body of the church, and persons have narrowly escaped serious injury. The alarm occasioned by these accidents led to the church being closed a few weeks ago, since which time an investigation has been going on as to the true condition of the building. A report was read to the Vestry, furnished by Messrs. Slater & Carpenter. Respecting the Four Evangelist columns, from which the main arch springs, Messrs. Slater & Carpenter reported that they were not constructed of the same material, nor were the several caps of the same height. The north-west and south-west columns were faced with Southam limestone to a height of 23ft. 6in., the upper portions of these, and the whole of the other two columns, being faced with Caen stone. They also mentioned that the other two columns are not of the same section, and that the arches overhead varied to the extent of three inches. Three of the Evangelist columns have "settled," in consequence of which the adjacent walls and arches were crippled and fractured. The north-west column was out of the perpendicular, and leaned 1¼in. westward. The south-west column also leaned westward 1in.; the south-east column 1in. southwards, and the north-east column 1in. northwards. The north and south walls of the nave were also out of the perpendicular, the former 1¾in., and the latter 3¼in., both walls leaning outwards. Messrs. Slater & Carpenter further mentioned that the small size and improper construction of the columns rendered them unfit to bear much more weight than had already been placed upon them. They also objected to the design, construction, and materials of the four great arches. The stones (Warwickshire sandstone) were not sufficiently hard for such a purpose; they were improperly jointed as well as imperfectly executed, and the arches having been erected without sufficient "centreing" they had settled irregularly, which had led to the portions of stone being driven off. The brick arches were not of sufficient thickness, and did not answer the purpose for which they were intended. In the end the Vicar announced his intention to open the nave for worship, and a resolution was adopted in favour of having the church inspected by a civil engineer.

MOLINE, UNITED STATES.—A new Congregational church at Moline, Iowa, was recently dedicated. The building is of brick, with heavy pilasters and dental work, and rests on a foundation of Joliet marble, cut in rustic. Its entire length is 120ft., and the average width 55ft. The styles are Norman and Gothic. The cost of the edifice is not far from 31,000 dols. The design was by W. L. Carroll, of Davenport.

BUILDINGS.

BANFF.—The new Court-house for Banff was opened on Wednesday week. The building is in the Corinthian style of architecture, and is built

of freestone. The court-room is 38ft. 3in. long, 28ft. 5in. wide, and 26ft. 6in. high. The rooms are heated by hot-water pipes. The cost of the building is £7,000.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

To OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—R. D. & Co.—J. H.—L. G. D.—J. H. & Co —R. & E. P.—T. B.—J. H.—W. A. B.—J. R. St. A.—G.H.G.—J.P.S.—C.B.A.

AN INDIGNANT PROVINCIAL.—We really don't know what you are driving at.

JOS. RILEY.—The advertisement was inserted in mistake.

BETA.—Your nice little letter on sandals is hardly appropriate for the BUILDING NEWS.

J. D. S.—Most of the numbers may be had.

AY. Z.—Next week.

Correspondence.

KITCHEN BOILERS BURSTING.

(To the Editor of the BUILDING NEWS.)

SIR,—At the inquest on the death caused by the bursting of the boiler of Mr. Rendell, C.E., we think he said that no safety valves yet invented are to be trusted. The true principle to go upon is to prevent the pipes from freezing. We have (acting under the guidance of an eminent authority in such matters, whose name we subjoin for your own information) succeeded in accomplishing this object, and, as we have patented the invention, we shall have much pleasure in submitting it to your consideration.

It consists of an iron tube screwed on to the up or down pipe near the range. The water enters at the bottom and comes out at the top of this tube. This tube is a cylinder, and open top and bottom, with a jet of gas burning through it, the whole thing being not unlike an argand lamp-glass, only the glass being hollow iron. The heat given to the water causes a very strong circulation through the pipes, and makes it impossible for them to freeze.

We adapt the same principle to the common water service pipes throughout the house, by adopting means to keep them empty at night, and keeping the water warm by means of our apparatus.

The whole is very simple and costs only a few shillings, and we think that after the trade and the public are warned through your columns that a simple remedy can be applied to obviate the constant danger of boilers bursting (besides expense of pipes bursting), the verdict of the jury will be very severe against any one who does not avail himself of it.—We are, &c.,

WATERSON & Co.

LUMP CONTRACTS AND THEIR SUBSTITUTE.

SIR,—Your article on "Lump Contracts and their Substitute" is to my mind a very comprehensive one; and goes directly to the root of all squabbles and vexatious lawsuits in the building trade. The scheme is evidently the result of long and thoughtful experience; and is to my mind preferable to that adopted by the London builders and the Fellows of the Institute—viz., the appointment of two surveyors, one nominated by the architect and one by the builders—and non-responsibility of client for any error. It is an axiom with me that as the client gets the benefit of the work, he, and he only, ought to pay for it; the builder certainly should be paid for his actual goods delivered. It seems to me obviously unjust to make either the architect or the surveyor responsible. "Professional odium," as you term it, would be a sufficient corrective of negligence or carelessness, and these are the only crimes for which any of the parties connected with the erection of a building should be asked to pay a penalty. Whoever thinks of asking his lawyer to pay for the result of wrong legal advice, or for the neglect or thoughtlessness of one of his lawyer's clerks? I have known several instances of considerable loss proceed from these causes, but "professional odium" is a sufficient deterrent to prevent a repetition. The correction of errors has always been a principle acknowledged by the Court of Chancery. Why not? It is absolutely necessary to good government. Every building contract—where there is a client, an architect, and a builder who want only what is fair—is a very simple matter, and seldom leads to a dispute. Builders, as a class, are no less honest than other men, and will, as a rule, do their duty when fairly treated; but there is a tendency to make them responsible, not only for their own errors and want of judgment, &c., but also for the errors, &c., of architects and their clerks—which has grown considerably of late years. It is no matter for wonder if some builder not overburdened with moral courage should attempt in self-defence to evade the strict fulfilment of his contract. The natural result of over-reaching on the part of the architect is either resolute resistance or evasion on the part of the builder. The firm with which I am connected has executed several works on the principle laid down by you. We have one on hand now for an influential railway company. The scheme you propose is, I believe, universal with their engineers. We have recently built a large hotel in the West of England on the same principle. In this latter case the quantities formed part of the contract, and payments were made monthly. Our application for every certificate was tantamount to notice for an appointment by the architect of a meeting of himself, the builder, and the surveyor at the building in the clerk of works' office. The architect invariably brought with him his own office copy of specifications and quantities, and, though our monthly certificates frequently exceeded £2,000, we could always agree upon the amount in about half an hour—no measurement of the building being necessary—simply abstracting such items from the priced quantities as were then executed, and approximately those partially executed. All extra works were measured up each month, when all day-bills were regularly rendered, corrected and certified, and for these works a separate payment was made, distinct in every respect from the contract sum. At these monthly meetings of architect, builder, and surveyor, such matters as delay occasioned by extra works, waiting for iron girders from Belgium, or other circumstances beyond our control, were adjusted on the spot, the terms of adjustment written on the extra bill, and signed by the architect. Hence all parties invariably met on the very best terms, and the adoption of a mutual "give and take" principle in trifling matters surmounted every difficulty. What the architect asked for was readily granted by the builders, and at the completion (some two months within the stipulated time) all parties were well satisfied, the directors especially, for they very handsomely paid us a bonus of £500 over and above the amount of the contract and claim for extra works. The architect in this case was a thoroughly practical man, holding high social status, with a considerable income independent of his profession.

Another of our contracts, for a very large town-hall, entered into in 1866, is executed on the same principle, but the working of it has been as different as it possibly could be. In this case, though there are large extras, every difficulty has been settled hitherto on the most amicable terms. In both these contracts, the former £25,000, and the latter over £50,000, the quantities were taken by independent surveyors, appointed by the architects, and no error of magnitude has been discovered in either case. Every builder should be paid to the full for all the work he does, and his contract should contain no legal clauses to prevent his obtaining this. The surest way to it is to incorporate the quantities with the specification and contract, at the same time protecting the proprietor against merely factious claims or fancied deficiencies. Errors in quantities are far more likely to occur in favour of the client than of the builder, because a surveyor cannot measure what is not shown on the drawings, and he may omit to measure something, or forget to put down as a multiplier the number of times any particular dimension should be repeated.

All extras or additions should be paid for at prices of, say, ten per cent. in excess of those in contract, because of the increased labour and attention required by the builder, as well as the confusion or disarrangement imported into the builder's arrangements, besides the expenses which are incurred by attending upon the surveyor—and in some cases absolute payment of half measurement, none of which are contemplated in pricing the estimates, each price being fixed at its minimum.

All deductions or omissions of work should be valued at, say, five per cent. less prices than those in contract for the same reasons. On one occasion our firm has actually had a contract in which these latter clauses were inserted, and in many others we have squared up the principle has been admitted by the architects.—I am, &c.,

A LARGE CONTRACTOR.

MEMORIAL TO THE LATE MARQUIS OF WESTMINSTER.

SIR,—One more has been added to the long list of be-muddled architectural competitions, so many of which have received well-merited publicity in your columns.

The Committee of the above Memorial issued no less than three different advertisements; first for "plans, specifications, and tenders," &c., for a cottage hospital to be erected at Shaftesbury, with the reservation usual in builders' competitions—"The Committee do not pledge themselves to accept the lowest tender." Next for "plans, specifications, and tenders," &c., but with the above reservation omitted, and "plans to be sent in under a motto, accompanied by a sealed envelope containing the name of the sender" substituted. Lastly, the following:—

"The Committee of the Westminster Memorial invite designs for a cottage hospital, to be erected at Shaftesbury, Dorset, in the Old English style of domestic cottage architecture. External walls greenstone, with box ground stone dressings, with brick internal walls, the roof covered with plain tiles. The hospital to contain six beds (in two double and two single rooms), a private room for the nurse, a day-room with south aspect for convalescents, kitchen, back kitchen, bath room, and offices. The architect to provide foundation plan, ground plan, one pair or bedroom plan, plan of roofs, four elevations, two sections, all drawn to a scale of 8ft. to an inch. A premium of 20 guineas will be paid for the approved design and drawings, which are to become the property of the Committee, who shall be at liberty to carry out the same (with or without modification) without further assistance from the architect whose plans are accepted, the premium to be considered as payment in full for the above-named plans, &c. The cost not to exceed £800. The drawings to be sent in on or before January 1st, 1871. For further particulars apply to the Hon. Secretaries.

"Shaftesbury, November 28th, 1870."

It will be seen the last advertisement is very explicit, the materials to be used, and even the "style" being specified. What the "Old English style of domestic cottage architecture" may be is doubtful; but one may perhaps logically deduce from a portion of the committee's syllogism that all cottage architecture in England is not domestic. This involves a doubt, and it is to be hoped that the committee will publish their selected design, so that the architects of England may be duly enlightened.

Through the course of a long and somewhat varied practice I have been lucky enough to steer almost entirely clear of competitions. The last (previous to this present one) that I entered upon was when I was "young and curly"—I am almost afraid to state how many years ago. The genial sportsmen of Dorsetshire wished to commemorate a county worthy, still beloved and living amongst them, whose chief claim to distinction was that he had kept hounds for fifty years at his own expense. A committee was formed and funds collected amounting to £1800. The committee would have a monument, and forthwith the usual tremendous bait was thrown out to greedy and impecunious architects. Designs were required for a column 100ft. high, to be built on the highest point of one of the bleakest of the Dorsetshire downs, totally inaccessible by any road, the column to have a staircase within, and sculpture without, and to be with or without an equestrian statue on the top. I resolved to compete; but my too tender conscience revolted against the equestrian statue. Why the tramway to get it to the top of the hill, and the scaffolding and other mechanical appliances to hoist it 100ft. high, would cost all the money the committee had to dispose of, and whence then was to come the vast column, the sculpture, and the winding staircase? I threw into my "design" a fox, a dozen hounds, half a dozen horses, and half a dozen scarlet-coated men, but as they were only accessories of the landscape and not of the column, I satisfied my too tender conscience, and (as I fondly dreamed) flattered the proclivities of the sporting committee as well.

Sir, I was not successful! An older hand than myself "embraced" in his design the fox and the hounds, supposed to be in the flesh, and the eques-

trian statue, supposed to be in stone. A kind of Hyde Park Corner "Duke" mounted on the top of the Nelson column—and, what was to the elder hand, no doubt, of more practical consequence, the enraptured committee rewarded his audacity with the premium.

The column was not erected; and I learnt afterwards, to my disgust, that the lucky (?) "prize-man" knew before he sent in his design that it never would be.

Experientia docet! Thus early I learnt that in architectural competitions, conditions are but empty words, and that while to be successful the architect must indeed be bold, he need feel no anxiety as to any assignable limits to the receptive capacities of ordinary committees!

But here, after the lapse of years, in the advertisement of the Westminster Memorial Committee, was matter once more to tempt one into the fussy arena of speculative competition, to gamble (not gambol) with straining frames, clean washes, ethereal greys, and vivid reds;—tremblingly I whispered with Young (and mine indeed were "Night Thoughts")

Some angel guide my pencil while I draw!

Seriously I thought it impossible at the present day that any architect would, be honoured with a premium who, designing a hospital, whether cottage, memorial, or however qualified, should forget that above all things, his hospital should *be* a hospital; that his first, second, and third should still be Hygiène, Hygiène, Hygiène.

But, alas! for fitness; alas! for the "Domestic Cottage" style!

Out of forty-two designs sent in, among them being some by men of experience and ability, the committee selected two, both of which more or less ignored the conditions of the several advertisements.

One of the two selected designs had upon it, *in full*, the name and address of the "sender," and another bore the motto "Perseverando."

The first was a Batty-Langley sort of design for a small villa, devoid of any special hospital arrangements, and in an art point of view simply beneath criticism.

The design of "Perseverando" has much more merit in it. It is fairly drawn and not extravagantly coloured, and is evidently the conscientious, and therefore so far praiseworthy work of a young man.

The elevations have the accustomed *rusticated* quoins of Bath-stone, stacks of octangular chimney shafts, moulded, capped, and based all in Bath-stone, regardless of expense; a plain square green-stone front wall, pierced by a centre doorway and by two tiers of small square-headed mullioned windows, the whole suggesting a doubt whether indeed the "Domestic Cottage" style is any new thing, or only that Early Gothic flower, which we cherished with such fond and possibly misguided affection during our pupildom.

As to "Perseverando's" plan, it is sufficient to note the salient features. General arrangement, cruciform, with front arm covered by a roof about 18ft. span, and of high pitch; the back nearly twice the width, covered by a roof of wide span and flatter pitch; wards for two beds, each 15ft. 6in. long, by only 10ft. wide and 11ft. high, having a window at one end only; corridors, only 3ft. 6in. wide; a central staircase, serving as a duct from ground to upper story, but with no roof ventilation: kitchen and scullery placed side by side under the wide flat roof, with no corridor of communication between the front portion of the building and the offices at the back of the kitchen; pantry opening direct into the kitchen; no hospital wash-house, so that the scullery, the kitchen, and the pantry are liable to be pervaded by the same ill odours; earth-closets, but with no provision for storing or drying earth, or for feeding the hoppers; the one nurse's day and bedroom on the first floor, leaving the convalescent room and the ward on ground floor free from supervision; no scheme of drainage whatever.

Such are a few of the features in the design of "Perseverando," but which, nevertheless, the committee have ultimately selected as the best.

They, however, show their sense of the fitness of the plan by calling upon the author to entirely remodel it, and also by withholding the promised premium.

Is this fair to the rest of the competitors?

Entre nous, I feel some commiseration for the committee plagued by forty-two designs!

The great French novelist says:—"What shall we do; we have only *one* Monthyon prize?" "Well, give it to some one who has done nothing to deserve it—that is the way the Academy mostly escapes from the dilemma!"—I am, &c.,

"L'HOMME QUI RIT."

RUDIMENTARY ARCHITECTURE.

SIR,—A little book useful to students who wish to get a general idea of the different styles of architecture, has lately been published, entitled, "A Rudimentary Manual of Architecture," by Thomas Mitchell. The preface states that it has had the benefit of the revision of three professional gentlemen eminently qualified for that purpose, yet not one of the three seems to have thought that the description of open timber roofs, on page 177, required any revision, although *king* and *queen-posts* are made to stand on tie-beams, and support the weight above instead of being suspended from the apex and supporting the struts, and the weight on the tie-beam below. Moreover, the straining beam between the heads of the queen-posts is spoken of as "a second tie beam." Such gross errors as these ought not to be allowed to pass unnoticed in a book intended for architectural students.—R. E.

Intercommunication.

QUESTIONS.

[2112] POWDER MAGAZINE.—I have been asked to furnish sketches for a powder magazine to be erected at a shooting range. It is to be 10ft. square, and 8ft. to wall head. Could any of our Volunteer architects give me a few hints?—S. B. W.

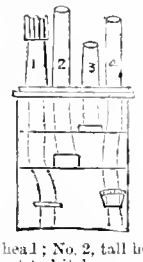
[2113] WELL SINKING.—I have a well 45ft. deep. The water comes from the bottom, as the sides were built in cement and pugged behind to keep out the surface water. I wish now to fill up the well with washed stones, so that I may not have so much standing water. The inside diameter of the well is 34in. Will some one kindly tell me how I may calculate the contents, so that I may only have my day's consumption at a time in the well?—AMATEUR.

[2114] FLOW OF WATER.—I should feel obliged if any of your correspondents would name the best formula for calculating the discharge of water from pipes. I want to know the quantity of water that a main of uniform size (say 6in. diameter, with a head of 180ft., and a mile and half long) will deliver in a given time. Also the quantity that a main of the same length and head, but composed of 9in., 8in., and 6in., pipes, would deliver in the same time. Also the quantity dischargable through, say, 20 ½in. taps, each running at the same time at the longest point of the said main. Would prefer the reply in plain figures, and would be glad if they would name some of the best works on the subject.—HYDRAULIC.

[2115] WROUGHT IRON GIRDERS.—I shall feel obliged if some kind subscriber to your journal will assist me in and show by figures how to calculate the depth, width of top and bottom webs, and thickness of iron plate to support a floor 1½cwt. per square foot superficial. The room

measures 20ft. 10in. by 20ft. An early reply will oblige.—ANVIL STOCK.

[2116] SMOKY CHIMNEYS.—I would feel obliged to any of your readers if they could advise me on the best means of curing four chimneys of smoking. I have tried several zinc pots without success. The chimneys are all together in the back stack of a six-roomed house, with kitchen built at the back, and carried by an arch into stack. I think the chimneys are nearly as straight in proportion as I have drawn them.—W. H. B.



No. 1, has a fluted head; No. 2, tall boy; No. 3, 2ft. red pot; No. 4, 4ft. red pot to kitchen.

[2117.]—TRADE PRICE LIST.—Can any of your correspondents inform me where I could get a Scotch trades' price list?—A JOURNEYMAN JOINER.

[2118.]—VENTILATING WINDOWS.—Having lately put in a new plate glass front to a shop, I should be glad if any of you correspondents could inform me of any means of keeping them free from condensed air, as during the greater part of the day things in the shop cannot be seen from the outside.—A SUBSCRIBER.

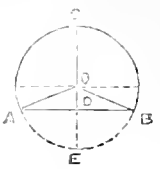
REPLIES.

[2079] COPYING ORNAMENTAL WORK ON TOMBSTONES.—As none of your correspondents have answered "I. M. A.," I will describe a simple method by which I have obtained copies of designs, either sunk or in relief. Obtain a piece of white paper, the thinner the better, and lay it over the design to be copied; then rub the paper, especially the edges of the design, with a piece of what shoemakers term heelball (black), which you could obtain at any shoemaker's. If you do this carefully you will obtain a well defined copy of the design in a few minutes.—FRANK CHESSELL.

[2087] ASPHALTE IN CHEAPSIDE.—Whether the heat is applied before or after laying the material does not affect the reply to the query. In defence of my statement I had the explanation of an agent of the company, and also their written description of the process in their lately issued pamphlet.—P. E. M.

[2090] TIN-LINED PIPES.—It is a great pity that the paragraph alluded to has obtained currency in this country. I can only suppose it originated in malice, it being opposed to the plainest facts. Water does not corrode tin, nor is there any probability of galvanic action being set up. Such action, if possible, would be but slight between these metals and would in no wise affect the value of an ingenious invention and most important sanitary aid.—P. E. M.

[2097] TUNNEL EXCAVATIONS.—The following is in reply to "Surveyor's" query in your issue for January 29. In the accompanying figure



Let C D = v = the versed sine of segment.
" A C = c = the chord
" A O = r = the radius B O = C O

Then to find the radius (r) of circle, of which the segment is a part, we have the followiog expression:—

$$r = \frac{c^2 + 4v^2}{8v} = \frac{c^2}{8v} + \frac{v}{2}$$

Also to find the number of degrees contained in the arc A C B we have sin L A O E = $\frac{c}{2r}$. Then 2 L A O E = L A O B, hence L A C B = 360° − L A O B, which call ϕ. Having found r and ϕ, we then have the following general formula for the area (A) of the segment:—

$$A = \frac{r^2}{2}(\phi^\circ \times \cdot 017453 \pm \sin\phi) \qquad 1.$$

The plus or minus sign in this form to be used according as the segment is greater or less than a semicircle. That is, if the segment be greater than a semicircle the plus sign must be used, and if less the minus sign. To find the area of a segment (when greater than a semicircle) having a table of areas of segments calculated to diameter = 1. Denoting the versed sine by v, and the radius by r, as before, put $p = 1 - \frac{v}{2r}$

Thus we find the value of p in the column headed versed sines, opposite to which value will be found the corresponding tabular area, which we will denote by t, then the area of the segment will be found as follows:—

$$A = 4r^2\left(\frac{\pi}{4} - t\right) = d^2(\cdot 78539 - t) \quad 2.$$

where d denotes the diameter of circle. The following rule for finding the area of a segment gives a very close approximation to the true result:—

$$A = v\left(\frac{2c}{3} + \frac{v^2}{2c}\right) \qquad 3.$$

When the segment of which the area is required is greater than a half circle, the area of the remaining segment must be found, and subtracted from the area of the whole circle, which will give the area required. Applying the data given by "Surveyor" to the first method, viz, $v = 15'3'' = 15{\cdot}25$ft., and $c = 21$ft., to find the radius we have,—

$$r = \frac{21^2 + 4 \times (15{\cdot}25)^2}{8 \times 15{\cdot}25} = \frac{441 + 930{\cdot}25}{122} = 11{\cdot}2397 \text{ or say } 11'24\text{ft.}$$

$$2r = 11'24 \times 2 = 22.48\text{ft.}$$

Again sin. L A O E = $\frac{21}{22{\cdot}48}$ = ·9341, the nat. sin. of 69° 5′

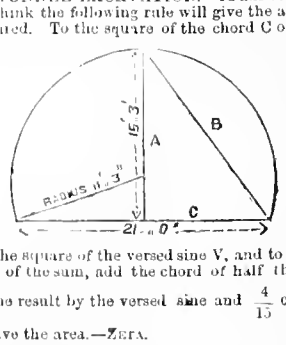
∴ 69° 5′ × 2 = 138° 10′ = L A O B. Hence 360 − 138° 10′ = 221° 50′ the number of degrees contained in the arc A C B. And sin. 221° 50′ = ·666966. Then by form 1 we get

$$A = \frac{(11{\cdot}24)^2}{2}(221^\circ\ 50' \times \cdot 017453 + \cdot 666966)$$

$$= 63{\cdot}1688 \times 4{\cdot}524979$$

=285·78 square feet area of segment. And by using form 2 we get a like result for the area. By the approximate formula (3) we get for the area 236·68 square feet, showing that it gives a result differing very little from the true one.—WILLIAM MOOR, JUN., Hetton Colliery.

[2097] TUNNEL EXCAVATION.—In answer to "Surveyor," I think the following rule will give the area of segment required. To the square of the chord C of the segment add the square of the versed sine V, and to twice the square root of the sum, add the chord of half the arc B. Multiply the result by the versed sine and $\frac{4}{15}$ of the product will give the area.—ZETA.



[2098] SPEAKING TUBES.—If a ½in. water pipe serves for whistle, and a 4in. iron pipe, I see no reason why a ½in. composition gas pipe should not do for the whistle, and a 2½in. iron pipe for speaking; the expense would be much less, and in some circumstances should act.—P.

[2101] TEMPERATURE OF DAIRIES.—I am obliged to your correspondent for the information kindly given, but

I do not understand how the right temperature is to be obtained in winter months except by artificial means. A cheese room requires, I believe, an even temperature of 65 deg., both in winter and summer; and in Wilts and Somerset I observe they keep portable stoves to warm the cheese rooms in winter months, a method very undesirable. I cannot see why the dairy floor should be 3ft. below the level of the outside ground. Would "Farmer" inform me if any purpose is gained by so doing? I think without a dry area round all the external walls or similar means, this would only conduce to a damp floor. To construct a cheese dairy for about 90 cows I propose to build it as follows:—Rectangular on plan; size, 36ft. by 16ft. in clear; of three floors—ground floor, the milk room; 1st, floor the cheese room; 2nd, floor a servant's bedroom, the communication to which would be from the adjoining farm house. This floor to be principally to shelter the cheese room from the heat of a slated roof in summer time. In milk room I propose the windows to be four in number, one in each wall, and made with the sashes to slide vertically, that the amount of air to be admitted can be regulated, and had either from the top or bottom of the windows, the glass to be thick rough plate, that it may not admit heat or cold so easily as common glass would do. The window frames externally to be covered with finely perforated zinc. Internally I would for cleanliness plaster the walls with Keene's cement, which would be washable and free from absorption. The temperature regulated by hot water pipes the water from which would be also used for washing of utensils. Would "Farmer" inform me if he sees any objection to these proposals, or can suggest improvements?—W. W.

[2109] WATER AND LEAD.—Lead may be adulterated with zinc, pewter, old solder, old printer's types, &c., but whether that be so in this case I could not say. Perhaps the water is the sole cause. As a remedy, under the circumstances, wash out cisterns, dry and rub lead with hard brush or carding, then paint them all over with red lead mixed with linseed oil, allowing it to dry properly before letting water in, and after water is in let it stand all night and run it off so that fresh water may be got.—P.

[2110] LOAD FOR MEMEL TIMBER JOISTS.—"Carpenter" should have given the circumstances under which the joist 12ft. by 4ft. and 17ft. bearing is intended to be placed, because if it is to have a plaster ceiling under it its deflection must be very slight under a "fair load;" but if it have to carry its load under circumstances where a considerable deflection would be of no account the fair load might be much greater. However, assuming that the circumstances will allow a deflection in the middle of ½in., the joist 12ft. by 4ft. and 17ft. bearing will carry 4326lb. uniformly distributed over it; or we may say 2 tons. I deduce this from the late Professor Barlow's experiments on the strength of timber, supposing that the Riga fir that he experimented upon was of equal strength to "Carpenter's" memel timber, and this, I think, may be taken as a fair assumption. The specimens that Barlow took for his experiments were, no doubt, of fairly good quality, and so we must assume the joist in question to be. A good deal depends upon the quality of timber (as upon that of every other material) when we are considering what weight it will carry. A knot near the lower edge of a joist and near the middle of its length will materially reduce its carrying power. "Carpenter" no doubt knows that if there be such a knot it should be turned to the upper side of the joist; in that case the joist will be but little reduced in strength.—C. S.

[2110] LOAD FOR MEMEL TIMBER JOIST.—The safe load for "Carpenter's" joist is 51 cwts., which is found by the following rule:—Multiply the breadth in inches by the square of the depth in inches and divide the product by the length in feet. Multiply the quotient by 3 (which is the weight in hundredweights required to fracture a bar 1in. square and 1ft. long), this gives the breaking weight of his joist loaded in the middle. Double the weight will be required to cause fracture when the load is uniformly distributed. The factor of safety to be adopted in practice is one-fourth for a fixed load and one-sixth for a moving load. The joist should be well strutted to prevent twisting. FRANK CHESSELL.

STAINED GLASS.

BEKESBOURNE.—The two lancet windows at the east end of Bekesbourne Church, Kent, have lately been filled with stained glass by Messrs. Lavers, Barraud and Westlake. Each window contains three medallions on a ground of rich diaper work. The two central subjects represent the "Crucifixion" and the "Resurrection of our Blessed Lord." The church being dedicated to God in honour of S. Peter, the remaining four medallions contain subjects from the life of that apostle.

SUTTON COLDFIELD.—One the four perpendicular divisions of the north-east window of the parish church has been filled with stained glass primarily to the memory of the late Mr. T. Colmore, and secondarily as a memorial to Bishop Hacket. The new memorial portion has been executed by Messrs. Valentine, of Edinburgh.

LAND AND BUILDING SOCIETIES.

NORTHAMPTON FREEHOLD LAND SOCIETY.—The annual meeting of the Northampton Building and Freehold Land Society was held at the Townhall, on Tuesday week, Edwin Marriott, Esq., in the chair. The annual report and statement of accounts were received and adopted. The report stated that 289 new shares had been issued during the year, while the withdrawals had been but 24. The cash received was nearly double that received in the previous year.

LEGAL INTELLIGENCE.

APPEAL FROM CONVICTION ON STRENGTH OF SUPERINTENDING ARCHITECTS CERTIFICATE.—This was an appeal tried on the 26th ult. in the Common Pleas against a decision of Mr. KNOX, the police magistrate, and the circumstances were these. The appellant was a builder in Tottenham-court-road, and in August, 1869, he erected a bay window to a house in Stratton-street, without having obtained the consent of the Metropolitan Board of Works This consent had been applied for and refused, and the superintending architect of the Board gave his certificate that the bay window was beyond the general line of building. The magistrate considered himself bound by the decision in "Bowman *v.* The Vestry of S. Pancras" to hold the certificate of the superintending architect conclusive, and therefore he convicted the appellant. The question now raised was whether the certificate was conclusive, or whether the magistrate himself was bound to decide whether the window was beyond the general line of building: and the case depended upon the construction to be placed on the 143rd section of the Act 19th Vict. cap. 120. The Court thought that there was great difficulty in constructing the statute, but adhered to their decision in Sparrow's case, that the certificate was not final and conclusive in reference to the line of frontage. There would be great injustice in holding otherwise, because the certificate was framed in private, without hearing parties interested, and was not necessarily published. Further, there might be varying certificates given by successive architects, and parties might not be aware which they were bound by. The magistrate himself was bound to decide whether the building was or was not beyond the line of frontage, and was not precluded from doing so by the architect's certificate. Judgment for the appellant.

Our Office Table.

ARCHITECTURAL ASSOCIATION. — To-morrow (Saturday), a visit will be made to the works in progress at the South Kensington Museum. Members will assemble at three p.m., at the entrance in the Exhibition-road. On Monday evening next, Feb. 6th, Lieut.-Col. Scott, R.E., will give the first of a course of four lectures on "Limes and Cements," at 7.30 p.m. The second, third, and fourth lectures will be delivered on Monday evenings, the 13th, 20th, and 27th inst. respectively, at the same hour. On Friday next, the 10th inst., the annual members' soiree will be held, at 8 p.m.

A NEW TUNNELLING MACHINE.—An interesting trial has just taken place of one of Brunton's tunnelling machines. A model was exhibited at the last conversazione at the Institute of Civil Engineers, and at the soirée of the British Association in Liverpool. The present trial was made in the grey chalk at Snodland, Kent, at the quarry belonging to Messrs. Lee & Son., of Holbrough. This demoostration was made chiefly to show the ease and rapidity with which a tunnel may be driven in such a formation as that which lies under the Channel between England and France. The rate at which the machine advanced was 3ft. 9in. per hour, in a tunnel 7ft. diameter, and it was obvious to those who witnessed the operation that the only real limit to the rate of progress would be the rapidity with which the waggons loaded by the machine's own action could be carried away.

EXHIBITION OF RUBBINGS FROM MONUMENTAL SLABS AND BRASSES.—A novel exhibition has been opened in S. George's Hall, Edinburgh, for the benefit of the Sick Children's Hospital. The exhibition consists of rubbings taken from stones chiefly in Argyleshire, and from brasses in some of the eastern counties in England, by "Unda," and they are shown for the praiseworthy object above stated by "Pet Jessie Anne." The pictures—for pictures they are, although of a rude character—are exceedingly interesting. They represent sepulchral slabs containing effigies of knights and saints, priors and minstrels, ornamental crosses and stone tracery.

DEATH OF TOMMASO MINARDI, OF ROME.—A Roman correspondent says:—The grave has just closed over one of Rome's brightest glories in the Modern School of Art. Tommaso Minardi, who, while led by his exceeding modesty to shrink from accepting charges which would have brought him forward under public notice, has amply shown in those works which he has left behind him how well fitted he was to have done so. He is best known to non-Romans by his copy of the "Last Judgment in the Sistine," almost his earliest work, and which attracted the notice of Canova to his rising genius; almost all the photographs sold in Rome of Michael Angelo's *chef d'œuvre* are taken from it, and it was exhibited by the Holy Father in the Exposition of Christian Art last year. His greatest service to the world of art, however, has been the formation of that school of artists whose patient works, too little observed by the world, have, under the present Pontificate, beautified so many churches of Rome with their frescoes. Gagliardi, who has so ably worked at the restoration of S. Agostino; Cochetti, at Sta. Maria in Trastevere; Fracassino, at S. Lorenzo; Guido Guidi, at S. Maria Nuova and S. Andrea della Valle; Bianchi, whose altar-piece in the Canons' Chapel at S. Peter's is worthy of its place among the achievements of the most celebrated masters; Mariani, Consoni, and many others, all owe much to his inspiration, as well as to the attention he enforced on their earlier studies to the rules of perspective and anatomy.

AMERICAN PINE.—The pine forests of Pennsylvania are, it appears, rapidly vanishing. For ten years past the consumption of timber to supply the numerous saw-mills of Williamsport alone has been immense. The *Bulletin* of that place states that the amount of logs "rafted out of the boom" for the present season will yield over 215,000,000ft. of boards. About 302,000,000 are annually manufactured at Williamsport, giving an aggregate in ten years of 3,000,000,000ft. It is impossible that this large consumption of raw material can continue for many more years. It is estimated that in ten or fifteen years the mountains will be denuded of every pine tree, and builders will be glad to get hemlock lumber. The Pennsylvanians may, at least, console themselves by reflecting that they have received their money's worth for their timber, and that it has been consumed in the fair way of business. But not the least serious lass to the French arising from the present war is that of the timber which has been so ruthlessly wasted, and which it will take many a long year to restore.

MEETINGS FOR THE ENSUING WEEK

MONDAY.—*Royal Institute of British Architects.*—"On Domes." By E. Beckett Denison, Esq., Q.C. 8 p.m.
Architectural Association.—"On Limes and Cements." Lecture 1. By Lieutenant-Colonel Scott, R.E. 7.30 p.m.
Society of Engineers.—First Ordinary General Meeting for 1871. Inaugural Address by the President. 7.30 p.m.

FRIDAY.—*Architectural Association.*—Members' *Soiree.* 8 p.m.

Chips.

The date fixed for the reception of architectural drawings at the forthcoming International Exhibition is Wednesday, Feb. 22.

Mr. James Sant, R.A., is gazetted the principal painter in ordinary to her Majesty, in the room of Sir George Hayter.

An "associated arts" company, comprising painters, sculptors, musicians, and architects, is about to be added to the 38th Middlesex (Artists'), Rifle Volunteer Corps.

We read in the *Academy* that some important rock-cut dwellings, many stories in height, have recently been discovered in Peru.

Timber Trade Review.

Grooved, tongued, and beaded Wyburg 1st yellow, ⅞in., 7*s* 3*d*; Dram 1st white, ⅞in., 7*s*.

Brisbane trenails, 40*s* per 1,000 pcs. 36in.

THE TIMBER TRADE OF LIVERPOOL DURING 1870.

In reviewing the trade of this port in wood during the past year, it will be seen that the total tonnage employed in the importation of wood has been 386,184 tons during the past, against 351,954 tons in the previous year. The business during the past year must be regarded on the whole as satisfactory; there having been a sound trade with a steady demand, and prices having been fairly sustained, shippers in most cases have found their operations result favourably. The continental war soon after it broke out caused a slight advance in Baltic fir, but beyond this, and checking to a moderate extent the export of furniture woods, it had no influence on our market. This year commences with favourable prospects, and gives hope of an increased demand for most woods, as the timber trade is in a healthy state and business generally in the manufacturing districts is improving, while the stocks now held here are in most cases moderate compared with many previous years.

The total imports from the British North American colonies have increased 2¼ per cent. during the past compared with the previous year, there having been employed 266,753 tons, against 252,598 tons in 1869. From Quebec the import of yellow pine in the log has been the smallest ever recorded, owing chiefly to the high cost in Canada having made shippers cautious in their operations. The Americans have again been good customers to the Canadian lumber-men, selecting the best qualities, and paying high rates for their requirements; and, so long as the demand continues from the United States, there is probably but little chance of the value of pine logs in Canada falling to a point which will permit of a large extension of trade with the United Kingdom. The consumption in Liverpool has been steady, and large square pine of good quality and waney board have ruled at high figures, but ordinary building timber has not maintained its price. Pitch pine and Baltic fir, having been cheaper, were freely used in substitution.

From North Europe the import of fir logs during the past shows an increase of 66 per cent. compared with the previous year, mainly in consequence of an unusually large supply from Sweden, whilst from the ports of Prussia and Russia the import is an average one. There has been a fair consumption, in some measure owing to the high price of Quebec yellow pine having directed the attention of consumers to Baltic woods as being suitable to their purposes, and much cheaper. No doubt a similar business will be pursued in the forthcoming spring, and nearly clear off the present stock of Dantzig fir before fresh supplies will reach this market. There is a large stock of Swedish fir now held here, say 250,000fc. (nearly three-fourths of the entire stock of Baltic fir), which will be found sufficient at the present rate of consumption to supply the requirements of the trade for some months to come. Of deals, battens, and prepared flooring boards, the import during the past shows an increase of 110 per cent. compared with the previous year, but, being in excess of the requirements of the trade, prices have ruled low. Battens and boards, though they have been freely used in the place of colonial spruce, have at times been difficult to sell, and just now the stocks of sawn fir are more than double those held at the like time last year, being 8,159 standard, equal to about six months' consumption.

Mahogany.—There has been a steady demand throughout the past year for home consumption, and selections suitable for this market sold readily, though the continental war checked, to some extent, the demand for exportation. Of St. Domingo the import during last year was 657,446ft., against 290,580ft in the previous year, being an increase of 126 per cent. Of Cuba the import during the past year has been the lightest since 1860, being 47,337ft., against 298,962ft. in the previous year. The sales yielded good results, figured logs realising particularly high prices. As the stock is exhausted, and the demand buoyant, this market never presented a more favourable opportunity for future business, and first arrivals will meet with ready sale at remunerative prices. Of Honduras, the import during the past year has been 503,882ft., against 1,722,108ft. in the previous year. Of Mexican the import during the past year has been 2,243,580ft., against 2,153,191ft. in the previous year. There has been a steady consumption for all descriptions, but prime figured logs from Santa Ana and Tabasco met with active competition, and realised good prices.—*Chaloner's Circular.*

CONTRACTS OPEN FOR BUILDING ESTIMATES.

Whitchurch, Feb 20.—For the erection of town-hall and markets in Whitchurch, Salop. Local Board Officer Whitchurch, Salop.

Wharfdale Union, Feb. 9.—For plans, specifications, and estimates for the erection of a new workhouse, to accommodate 150 inmates, exclusive of vagrants, on ground situate at Newhall, near Otley. C. J. Newstead, clerk to the guardians, Board-room, Boroughgate, Otley.

Whitchurch (Whitchurch Local Board), Feb. 20.—For the erection of town-hall and markets in Whitchurch, Salop. S. M. Lockwood, architect, 85, Foregate-street, Chester.

War Office, Feb. 25.—For works and repairs, and supply of building materials to War Department. Buildings and property at Ashton-under-Lyne, Birmingham, Bradford, Burnley, Bury, Carlisle, Chester, Coventry, Fleetwood, Hartlepool, Isle of Man, Leeds, Liverpool, Manchester, Maryport, Newcastle-on-Tyne, Northampton, Paull-on-the Humber, Preston, Scarborough, Seaham, Sheffield, Stallingborough, Sunderland, Tynemouth, Weedon, Whitehaven, and York, including the surrounding neighbourhoods, from the 1st April, 1871, till 31st March, 1874.

War Office, Feb. 14.—For the supply of materials, and for the performance of such bricklayers', masons', paviors', carriers', carpenters', slaters', smiths', gas-fitters', plasterers', plumbers', painters', glaziers', and paper-hangers' works and repairs (the estimate for any one work or repair not exceeding £500) as may be required by the Royal Engineer Department at the following stations in the Dover district, viz.:—Dover: fortifications and barracks at Dover, and from Dover to No. 1 Tower westward; and from Dover to (but exclusive of) Walmer Castle eastward. Ramsgate; from Walmer Castle, including No 2 Battery, Sandown, to Ramsgate and Margate inclusive: Canterbury: barracks. Shorncliffe Camp: including the Royal Artillery Barracks, the temporary barracks, Sandgate Castle, Folkestone and Shorncliffe Batteries, and towers from No. 1 to No. 9 inclusive. Hythe: including Hythe Barracks, coast defences, from 10 to No. 24 Tower inclusive, and Royal Military Canal from Seabrook to Warehorn Rye: including the coast defences from No. 25 Tower westward to Fairlight, and the Royal Military Canal from Warehorn to Cliff End. T. B. Collinson, Colonel, Commanding Royal Engineers, Royal Engineer Office, Dover.

Bolton.—Contract C.—March 3.—The Corporation of Bolton are prepared to receive tenders for the joiners' work, plastering, painting, glazing, and plumbers' fittings required for the completion of the new town-hall. The drawings and specifications may be seen, and bills of quantities obtained, on application at the offices of Mr. William Hill, architect, Park-square, Leeds; or at the offices of Mr. George Woodhouse, architect, St. George's-road, Bolton, between the hours of 10 a.m. and 5 p.m., from the 16th day of January next to the 3rd day of February next. Sealed tenders are to be sent in not later than 12 o'clock at noon of Friday, the 3rd day of March next, addressed to the undersigned at the Corporation Offices, Acres Field, Bolton, and endorsed "Tenders for the Town-hall, Contract C." R. C. Hinnell, Town Clerk.

Bakewell (Derbyshire), Feb. 16.—For the new schools. A. Salvin, architect, 19, Cranley-place, Onslow-square, South Kensington.

BRISTOL LOCAL BOARD OF HEALTH, Feb. 23.—For constructing and completely finishing certain intended brick sewers, valve chambers, and other works in "The Avon Intercepting Sewer District." Length of sewers about 7563 yards, varying in size from 3ft. high by 2ft. 6in. wide to 7ft. 6in. in diameter. John G. Heaven, Clerk, Local Board of Health Office, 13, Prince-street.

BISHOP'S STORTFORD.—Contract No. 2.—Feb. 17.—For sewage, screening and storage tanks, engine and boiler-house, and engine-man's cottage, with the necessary connecting pipes and valves, and an approach-road. Contract No. 3.—For duplicate boilers, engines, and pumps for lifting the sewage. William Gee, clerk, Bishop's Stortford

TORQUAY.—Torquay Hotel Company (Limited), Torquay, Devon.—Feb. 29.—For the erection of additional buildings, &c. Mr. J. Allsop, secretary.

SHOREHAM AND DISRICT WATER, Feb. 11.—For the machinery, mains, reservoir, &c., necessary for these works. J. W. Wilson, engineer to the company, 111, Victoria street, Westminster.

PORTSMOUTH, Feb. 20.—For the erection of a church at Portsdown, five miles north of Portsmouth. John Colson, architect, St. Swithin's-street, Winchester.

GUISBOROUGH CEMETERY, Feb. 10.—For the various works required to be done, viz., the erection of two chapels, gate lodge, mortuary chapel, out-offices, fence-walls, and the effectual drainage of the field. William Weatherhill, Clerk to the Board, Guisborough.

CREWE LOCAL BOARD, Feb. 15.—For a non-condensing horizontal pumping engine and boilers; also a condensing beam engine and boilers, for their sewage works at Crewe. Frederick Cook, Clerk to the Board, Temple-chambers, Crewe.

BANKRUPTS.

(TO SURRENDER IN LONDON).

John Dyring, Meads, Leyton, Essex, and Fish-street hill, surveyor, Feb. 16, at 11·30.

(TO SURRENDER IN THE COUNTRY).

Thomas Thorogood, Reabourn, carpenter and builder, Feb. 22, at S. Albans—James West, Chichester, builder, Feb. 16, at Brighton.

BANKRUPTCIES ANNULLED.

James Edward Butcher, Sutton, Surrey, builder, Dec. 21—John Pramel Ree, Bute Foundry, Cardiff, engineer, Jan. 26—John Stanley, Yarmouth, stonemason, Jan. 26.

PUBLIC EXAMINATIONS.

Feb. 16, G. Roots, Bradburn Riverhead, near Sevenoaks, brickmaker and woodseller—Feb. 22, D. Graves, Birmingham, builder.

SITTINGS FOR LAST EXAMINATION.

Feb. 15, H. Venthem, late of Chapel-street, Bedford-row, builder.

DIVIDEND MEETINGS.

Feb. 16, S. Keetch, Hornsey-road, Holloway, carpenter.—March 1, T. Davis, Mountain Ash, Glamorganshire, builder—Feb. 11, T. W. & H. Panton, Monkwearmouth, ironfounders.

INSOLVENT DEBTORS' DIVIDENDS.

G. Hinves, late of Park-place, Highgate, builder, div. 5s. 9d.

DECLARATION OF DIVIDENDS.

J. Brayford, Walsall, iron manufacturer, div. 1s. 9d.—T. V. Leverage, Cambridge, builder div. 9¼d.—G. King, Cheyne-walk, Chelsea, timber merchant. div. 3s.—H. Ashton, Manchester, ironfounder, div. 1s. 0¼d.

PARTNERSHIPS DISSOLVED.

Gilbert & Brenchley, Wharf-road, City-road, galvanised iron manufacturers.—Baggeley & Son, Stoke-upon-Trent, stonemasons—Stannard and Barnard, Leicester, architects—Mayer & Co., Old Broad-street, City, timber merchants.

THE BUILDING NEWS.

LONDON, FRIDAY, FEBRUARY 10, 1871.

IMPEDIMENTS TO SANITARY PROGRESS.

THE majority of our readers will receive, as we have done, with great satisfaction, the announcement made by Sir C. B. Adderley, M.P., and which we have given in another place, that the Report of the Sanitary Commission is nearly complete, and that Mr. Bruce and two of his colleagues are now engaged in the preparation of a Bill to improve and consolidate the Sanitary Laws. With a more energetic Home Secretary, we should have better hopes of an early result; but so glaring are the defects of the present system—or rather, we should say, no system—and so urgent is the necessity for reform, that we do not despair of a measure passing the next Session of Parliament that will reduce into one intelligible statute the multifarous Acts which have passed the legislature since the Public Health Act of 1848. Never did any body of statutes—and they have been crowded upon one another in every Session of Parliament—more require modification. They have become eminently not only mystifying but mischievous, for it is impossible for any plain man to understand them; and we have known lawyers of large experience in other branches of the law confess their inability to advise for them. They have been hurriedly prepared, and with equal hurry passed through Parliament, to meet some particular emergencies as they have arisen, and without reference to any general principle of sanitary science, or any regard to the common law of England.

At such a moment it may be useful to glance at the origin of this voluminous and unsatisfactory legislation. It commenced with the Public Health Act already referred to, and that measure was, as many of those who promoted it now admit, premature and imperfect. The agitation that led to it originated with the outbreak of cholera in this country, and the inquiries that were set on foot, and the reports founded upon the results of those inquiries, are even now most valuable and instructive documents. It was shown that a large bulk of our population were living in a state little better than savages; that the ordinary decencies of life were not practicable, and therefore the moralities were impossible. These revelations, statistically recorded, interested good and active men of all sects and and all parties; but when practical measures were spoken of, they were opposed by vested interests and by small and close corporations. The sanitary reformers, however, did much good, and conferred a lasting benefit upon the community by the efforts they made to enlighten the public mind; but all social reforms must be slow, and the strenuous demand for legislation was no doubt a mistake, as all law making must be that is not demanded and supported by public opinion. The public at large had no knowledge on the subject, and were not prepared to follow the enlightened few who thought it ought to be the first care of Government to protect the health of the governed. Besides this, there were many political agitations appealing to the people, and these have always the most influence upon the great masses. We believe that it was rather against the conviction of Lord Morpeth, afterwards the Earl of Carlisle, under whose conduct the Public Health Act was carried through Parliament, that he pressed the measure on. He had misgivings that the subject was not ripe for legislation, but he yielded to the pressure put upon him by those who had worked themselves into a state of enthusiasm, and some of whom seemed to feel that an Act of Parliament was the end rather than the means by which the end was to be attained. We had the assurance of several members of Parliament at the time that nothing but the known high character and amiability of the noble lord could have carried the measure through the House of Commons, so strong was the conviction in the minds of many who were favourable to legislative action that there was not sufficient information in the public mind to give the measure its proper and full effect; and they thought it was better to wait until a complete measure could be passed than accept what must necessarily be an imperfect one.

The fears of those gentlemen have been fully justified, for that imperfect measure has been followed by still more imperfect amendments, and under them local authorities have been formed, which have become an injury rather than a good to the neighbourhood over whose sanitary arrangements they preside. Year after year rates have been levied to carry out ill-conceived and hastily-developed schemes, and the attendant disappointments and failures have led to party strife and bickerings of all kinds, to sordid contentions and quarrels, and comparatively little has been done to effect those salutary changes which the sanguine supporters of the measure expected, and which the necessities of the case demanded. The mania for law-making, which is one of the great evils of our time, has played its gambols to a woful extent with our sanitary laws, and those who will look at Glen's work, "The Public Health and Local Government Laws," will observe that we have been drifting from bad to worse, until the law is in a state of inexplicable confusion. It is apparent that the framers of the laws have rushed from one extreme to another, and have opened the way by which small bodies of men may obtain almost absolute power over a neighbourhood. It matters nothing to the purpose whether such powers are placed in the hands of men who will use them for worthy purposes, or with sinister aims; every observing man knows the danger of breaking down the safeguards which our constitution has built up and fortified against the usurpation of small minorities, to the injury and oppression of the majority.

As a practical exemplification, we may point to our Local Boards of Health. There is a loud outcry against them, and the method adopted by the recent Acts is to give greater facilities for their formation by minorities, while the true method to break down opposition and to make them useful would have been to make them more truly representative. There is no class of institution more unpopular, and why should this be? The objects they aim at are highly desirable, are even essential to social progress. There is nothing unattainable in those objects if they were sought to be secured by patient and business men. Then what is the reason they do not enlist the cordial feeling of the classes that, if successful, they would benefit the most? It is simply because, in most instances, they have commenced on a system of clumsiness which the law has encouraged, and which is always offensive to Englishmen. It is found easy to establish a Board, and the members absolve themselves from the duty of conciliating, or even consulting the feelings and wishes of those who have to contribute the rates. It is strange that in this day an old-fashioned vestry can call a meeting by simply placarding an announcement on the church door, and that such vestry meeting can appoint a sewer authority, and that another vestry meeting can levy rates to cover a large expenditure, an expenditure of thousands of pounds. Many instances of this kind occur to us, but we prefer to cite one, the particulars of which have been supplied to us by a correspondent.

In the Parish of Beckenham a sewer authority has been formed, and, as it appears, has already challenged opposition. This parish is governed by an open vestry, of a very old-fashioned kind, holding its meetings at twelve o'clock at noon. Now this vestry, which might do very well when Beckenham was a village some ten miles from London, is scarcely adapted to the wants of Beckenham when it has become a growing suburb of the Metropolis; nor is the hour of meeting suited to the convenience of gentlemen residing there, but whose occupations are in London. So far as we gather from this report, a vestry meeting of the parish appointed a sewer authority, and this authority forthwith employed a surveyor and prepared a plan of drainage and irrigation the cost of which was estimated at £31,800. When this scheme was so far advanced as to be ready for Parliament, the same vestry levied a rate to defray expenses. This rate was opposed, as it will be seen, by several persons, but without any success, as the magistrates have no jurisdiction. This sewer authority is formed under the Utilization Act of 1867. The letter sent to the magistrates by one of the gentlemen who had resisted the rate is explanatory of the whole case, and is a most suggestive document.

We have no intention of giving any opinion upon the points in dispute, but we think that the principle involved is a most vital one, and we cannot be surprised that the acts of such an authority should rouse the most vigorous resistance. We will suppose, and we see no reason to support a contrary supposition, that the sewer authority is acting with the most perfect good faith, and with an earnest desire to benefit the neighbourhood; but what do we find when we look over the report of the scheme which has been sent to us? Why this—That an outlay on drainage and irrigation works for district with a population of 5,000 persons amounting to no less than £31,800 is contemplated, and the first steps taken by an authority appointed by a vestry convened at twelve o'clock in the day by a placard on the church door, and by an advertisement in a newspaper that circulates in the country. This is all that the Act requires, and therefore this authority has acted legally beyond dispute. No steps have been taken, and none are necessary under the law, to consult the general feelings of the ratepayers as to this large outlay. But there is another feature of the case which it is important to notice.

In looking over the report we find that the sum of £10,225 is set down for works, and £20,800 for land on which to construct sewage farms. The land is estimated at £450 per acre, and belongs to a landed proprietor of the neighbourhood. There is nothing in this but what is consistent with perfect fairness on both sides. But would not suspicion naturally arise in some minds? Mistrust of public men and public bodies is a common feeling, even when the intentions are conspicuously upright; but under these circumstances the strictest scrutiny would not only be justified, but become a duty. Is not £450 per acre a large price to pay for land for irrigation purposes, and would not land of that value be building land, and inconveniently near to an inhabited neighbourhood? But the question left to decide is this—whether it is expedient or right that the settlement of such grave and weighty questions should be left in the hands of a few men elected by such a method as is open under the law. It is a grievous mistake to allow such a body of men to undertake so serious a responsibility, and to leave the great body of the ratepayers so entirely unrepresented. In all remedial measures a sympathy between the administrators of the law and the people is indispensable to success, and where this is destroyed, heartburnings, dissatisfaction, and lasting bitterness spring up. No doubt the new statute will provide a remedy to this serious evil. It is inconsistent with our general principles of legislation, that any authority should be established with rating powers without establishing at the same time the most stringent guarantees against abuse, and no guarantee will be ever found so effectual as that of insisting upon

publicity in every stage of its proceedings. Whenever public money has to be collected and disbursed, every reasonable check ought to be imposed upon those who have to expend it.

We observe in the case which we have quoted, that on the appeal of one of the aggrieved parties the case was adjourned. This shows that the justices are not certain as the powers of the law they have to administer, and probably indicated a sympathy with the appellants.

One of the first necessities of the case is to enact that all authorities with rating powers should be elected directly from the rate-payers, and that the initiatory steps should not be taken but on a requisition of two-thirds of the rate-payers, such initiation to be approved by a central authority duly represented in and responsible to Parliament.

QUAINTNESS OF STYLE.

IN the inaugural lecture of the series delivered by Mr. Ruskin at Oxford on the subject of Art, in his capacity as Slade Professor, there occurs the following memorable passage :—"So far as I may, I shall discourage all admiration founded on quaintness or peculiarity of style ; and repress any other modes of feeling which are likely to lead rather to fastidious collections of curiosities than to the intelligent appreciation of work which, being executed in compliance with constant laws of right, cannot be singular, and must be distinguished only by excellence in what is desirble."

It has been by the powerful and clear enunciation of the broad principles which should govern all the arts that Mr. Ruskin has justly earned his high position as a teacher, and his Professorship at the University of Oxford. We believe, with him, that his "proper function is not to acquaint his hearers with the general history, but with the essential principles of Art." Herein we suspect we shall find the system adopted in his lectures at variance with that of his brother Professor at Cambridge, Sir M. D. Wyatt. To that learned author—we use the word advisedly—we should certainly turn if we desired to glean either the general history of Art, or the particular history of any of its branches ; but we should as certainly not select him as a Gamaliel, to sit at his feet for instruction in the principles which should guide our own practice. With all his acknowledged energy and multifarious reading, we are forced to judge by his works that he has much to learn himself before he can be expected to direct others aright, and he must extricate himself from the unfortunate slough of impurities bred by the Renaissance style which he affects before any preaching as to truth of construction or sobriety and appropriateness of ornament can have much effect from his lips.

The passage which we have quoted above from the inaugural lecture of Mr. Ruskin deserves careful consideration. The quaintness of style which he deprecates is the especial bane of modern artistic work, and particularly in the branch of architecture. We recently, in an article upon the Queen Anne mania, warned our readers of the most recent development of that prejudicial quality. The tendency of the present day is for artists to run into extravagances to secure notoriety. Vanity, of course, is the root of the evil. A royal road, a short cut to fame, is the object proposed.

Art is but a language for the expression of thought, and is liable to the same errors as literal language. The penny-a-liner indulges in extravagances to secure attention, and writes not to teach but to strike. But the vice is not confined to penny-a-liners, since even such an author as Carlyle coins outlandish words and tortures the Queen's English with the same end ; and many of our best poets, such as Browning, often cannot condescend to be intelligible.

So it is with too many of our artists ; they cannot work their way up gradually like Turner, who apprenticed himself to learn all the simple lore that nature teaches, and then to the painters of ancient celebrity one by one, following the secret and practice of each till he could surpass them all on their own ground before he strove to soar after the deeper mysteries which no one before him had gleaned from the more cunning effects of nature, or trusted to the pinions of his own imagination.

So again with our architects. They will run before they can walk. They do not care to be intelligible ; they do not think of their art as a language which they have to master to talk correctly therewith, and the object of which is to convey ideas and be subservient to common sense. When one sees the extraordinary gymnastic pranks of the Mediæval extravagants of the day to attract the attention and extract coppers out of the pockets of the public, we feel inclined to remonstrate with them as the old lady in *Punch* did with the peripatetic street acrobats, and to tell them that we would far prefer to pay them to proceed right end uppermost.

Then how we long to tell the pseudo-Classic students that we are heartily sick of their nonsense verses, and are ravenous for plain prose for a change; that their misplaced columns and entablatures are as patent an offence to the educated eye as gross faults of grammar to the educated ear ; that a pediment broken in the middle is as great a perversion of architectural as a bad pun would be in articulate speech. Had we dared, we should have told Mr. Currey, when describing his gratitude to Mr. Ransome the other night at the Institute of Architects, for enabling him, by the cheapness of his artificial stone, to garnish his S. Thomas's Hospital with some hundred of mock-pots, that we would that the Chancellor of Exchequer would levy a prohibitive tax upon such useless monstrosities. How we would like to fine Messrs. Banks and Barry, or Mr. Cockerell, every time they made a cruet-stand of obelisks, such as those which disfigure the sky-line of the buildings of the former in Victoria-street, and the design of the latter for the National Gallery ; and how we hope that Mr. Ayrton may prevent any such indulgence on the part of Mr. Edward Barry, in the structure which we hope he is soon to raise for the last-named purpose in Trafalgar-square.

We have sometimes rebelled against the Biblical iteration of the use of the several members of the body, and have thought that the most uncivilized savage hardly needed to be so constantly told that his eyes are to enable him to see, and his ears to hear, his hands to handle, and his nose to smell, but really our architects need constantly reminding of the practical use of the simplest architectural features—that doors are for entrance, and windows for admission of light, and roofs to give shelter. What is a pediment but the end of a roof ? If so, why is a hole often cut out at the top of it, rendering it as useful as a hat would be without a crown ?

The architectural profession may well take this counsel to heart, that until they make their artistic language sensible and intelligible, the public will not concern themselves about it. They find it now a strange dialect, which they are unable to comprehend, and which, therefore, they object to have to pay for. In the interest, then, of the profession, as well as that of the public, we would say what we have often said before, and intend to say again—In architectural matters let there be reason in all things, let common sense be the basis of modern practice in this art, and let architects affect neither quaintness nor unintelligibility. "If any man speak, let one interpret, and if there be no interpreter, let him keep silence in the church." G. P. E.

A new general post office for Colchester is to be built in Head-street.

MESSRS. BACKHOUSE AND CO.'s NEW BANK, SUNDERLAND.

THIS building, which has just been completed, from the designs of Mr. George Gordon Hoskins, F.R.I.B.A., of Darlington, has four frontages, which are entirely of stone, the description of work being termed pitched blocker walling, of Pensher stone, with Dunhouse stone dressings. The main front faces the High-street. It is divided into three bays, terminating with gables, with carved stone crockets and finials ; within a panel in each of the side gables, which abut upon Norfolk-street and West Sunniside respectively, is carved the shield from the coat of arms of the Backhouse family, the middle gable being furnished with an oriel window, supported by a buttress and red Aberdeen polished granite shafts with carved stone caps. From the side gables occur certain projections of the quoins or angles forming the ends of balconette cills to the second-floor windows, the corbels supporting those projections being represented by grotesque animals, which have been carved from the architect's design. Other fantastic figures are placed at the angles of the several string-courses. The principal entrance doors and windows on the ground-floor have segmental pointed arches, the mouldings of which consist generally of alternate rounds and deeply-cut hollows, producing a strong effect of light and shade ; these arches are supported by columns of red Aberdeen polished granite, with mid-bands and carved stone caps, the foliage of which is of a conventional character. The entrance to the bank is from the High-street, by a porch or vestibule at the north-east angle, the floor of which is paved with encaustic tiles, executed by Messrs. Maw & Co , the ceiling being of panelled timber. This vestibule is lighted from the east by a large circular window of geometrical plate tracery, filled with stained glass by Messrs. Lavers & Barraud, of London, representing the armorial bearings of the firm. The south wall is furnished with an arcade of segmental pointed arches, supported by columns of polished Cairngall granite, with carved stone caps and cornices. Passing through the swing-doors on the west, we enter the banking room. The size is 34ft. by 28ft. ; but in addition to this the bank proper consists of a second space, 23ft. by 11ft., for the accommodation of some of the clerks, and serves as an approach to the strong-rooms. This portion of the room is divided from the main by an arcade of moulded stone arches supported on massive columns of polished red Aberdeen granite, with carved caps. The whole of the woodwork is of wainscot oak, except the panel moulds of the framing and staffs of the architraves, which are of Spanish mahogany. The room is surrounded by a dado 4ft. high. The portion of the flooring appropriated to the public in front of the counter is laid with the same description and pattern of tiles as those in the vestibule. At the east and west ends of the room are chimney-pieces of black marble, relieved with Egyptian green and inlaid with serpentine marbles, and provided with black marble fenders and tiled hearths, executed by Messrs. Nelson, of Carlisle. The private office has its entrance from the public portion of the banking-room, the furniture being specially designed by the architect. The portion of the building above the bank proper is arranged as two commodious dwelling-houses, with their entrances on the east and west fronts. These are occupied by two of the clerks. The contractor was Mr. George Gradon, of Durham ; the carving has been executed by Messrs. Farmer & Brindley, of London. The works have been in hand a little more than two years.

[We hope to give an exterior view of the building next week.]

ROYAL ALBERT HALL.—We understand that at the ceremony of opening the hall by the Queen on the 29th of March, an officially-reserved free seat will be offered to the Mayor, Provost, or Bailiff of every place in the United Kingdom which paid £100 and upwards to the subscription fund of the Exhibition of 1851.

LONDON AND COUNTY BANKING COMPANY.—The usual half-yearly meeting of this Company was held on the 2nd inst. A dividend on the capital of the company was declared at the rate of £6 per cent. for the half-year ending Dec. 31, 1870, with a bonus of 3 per cent., payable on and after the 13th at any of the company's banks. Good fortune, the result doubtless of good management, certainly continues to attend the operations of this bank.

THE NEW LOAN PICTURES NOW ON VIEW AT THE SOUTH KENSINGTON MUSEUM.

SURELY this generation has grand opportunities for studying art! If culture in this direction is the way to make the masses love the beautiful, and culture in art is to be obtained by seeing good works of art, then even people who are unable to pay a shilling to view the Old Masters at the Royal Academy may see them, and fine specimens of them too, for nothing, at the South Kensington Museum. Leslie was wont strongly to impress upon young painters the desirability of remaining in London to learn their profession, instead of travelling on the continent in search of art-knowledge. If he held such opinions in his day, surely they would be greatly strengthened now. Let us consider, for instance, the many fine collections lent on loan to various exhibitions, and the number of rare old pictures exhibited in London since October last. First there was exhibited at the Institute of Painters in Water-colours a very fine collection of the works by the earlier members of this branch of the profession; then in the Suffolk-street Gallery were exhibited, also to benefit a charity, a number of Velasquezes and other valuable paintings. In January the Royal Academy opened its second Old Masters' Exhibition; and the South Kensington Museum, besides having on view the collection of Lord Elcho and several of Lord Westminster's finest pictures, has now within its walls a splendid collection (with some exceptions) formed by the late Munro of Novar, now in the possession of his sister, Mrs. Butler-Johnstone. Not but that even there it is a pursuit of knowledge under difficulties, for the authorities seem to be not overburdened with space for exhibiting their treasures; and large as the museum is, it appears not large enough for the number of works of art it has to contain. The present collection is placed about on screens upstairs and downstairs, and to find the various pictures we must wander about from one gallery to another, till our sense of locality is hopelessly disturbed and paralysed. In the gallery where Lord Elcho's pictures are placed is a very fine Rubens hanging on the screen. The subject is the Virgin and Infant Saviour, with S. Elizabeth and S. Joseph. The drapery of S. Elizabeth is painted with great vigour, particularly the fur, which is very finely handled. Rubens is not the painter we should choose for the delineation of sacred subjects; and in this instance, though he has produced a real work of art, it is not at all religious in feeling. Any one wanting to see the *bravoura* of execution, and the perfection of rich juicy colour, should study Rubens, and this picture particularly, but for religious feeling he must go to the Italians. Another fine colourist, but of modern times, whose pictures hang on a screen in the next room, is Etty. His "Good Samaritan" is perhaps one of the happiest efforts of his brush. It is of small size, but very fine as to colour. The head of the Samaritan is grand in character; he has dismounted from his ass (which is caparisoned rather after a Spanish than an Eastern manner) and is pouring oil into the wounds of the disabled voyager, whose flesh, by the way, is rather that of a man in prime health than of a traveller stripped and half dead. In the distance, the men who have passed him by on the other side slink meanly away. Another fine Etty is "Diana and Endymion." The painter has so contrived the figure of the goddess that she takes with her floating and white gossamer draperies, almost the form of the crescent moon. The shepherd Endymion is reclining asleep against the heathery cliff, with his sheep dog at his feet. Underneath this work is a picture of three nymphs, very fine in colour, with the flesh beautifully painted. The rich hues of the suspended drapery enhance with great effect the delicate tones of the flesh. This collection contains no fewer than five fine Turners. The most splendid among them is, perhaps, the "Venus and Adonis." In treatment it is something like Titian, and the arrangement of the background reminds us of the Peter Martyr. The ramping dogs are as fine as Snyder's. Perhaps this is one of the best works for understanding the versatility of Turner's uncommon talents, and the easy way in which he could throw himself into the spirit of another painter. Indeed, in one of his pictures, "The Blacksmith's Shop," Turner was accused by Cunningham of trying to injure the art of Wilkie by an imitation of his peculiar manner, but it was only one of the eccentricities of Turner's genius, showing how, under all circumstances, he is truly great. Another very fine work by him represents the winding of a river passing through a city, and gradually widening and broadening out in the distance to the blue sea, which, in its turn, merges almost imperceptibly into the brilliant summer sky. On one side of the river rises in terrace upon terrace the fair Italian-looking city, glowing in the sunlight. In the foreground wave such trees as only Turner paints, not individualised but poetically rendered, while behind them in the middle distance are the rosy mountain peaks. The reflections in the calm blue river are wonderfully given. The sky appears to us a little injured in some places, and there are some dirty marks upon it, which might advantageously be removed. "The Piazza of S. Mark" is painted with a cold evening light. Some festa is taking place, for many people are gathered on the piazza, and fireworks are being let off from boats on the canal. The fourth Turner has for its subject the setting sun in some great city. The yellow sun reflected in the water is gradually sinking in the west, but has still power enough to light up with golden colour the walls of the palaces on the brink of the river—such palaces as seem only to have been imagined in dreamland, not to have ever been seen on the common earth. Turner almost always contrives to do this. He lifts you above and beyond those regions which people can see with their own eyes, into something usually reserved for the vision of the poet alone. The least attractive of his works here is "The Avalanche," which appears to us dirty, and not handled with his usual power. In the Cartoon Gallery, also placed on screens, hang perhaps some of the greatest gems of this collection. Among them is a very fine Rubens of "S. Sebastian," rather larger than life, painted coarsely perhaps, but with masterly vigour of execution. The saint is tied to a tree, the only light in the background being a ray of light against the horizon. Near to this picture is placed a fine Ruysdael, a sea-piece, or rather a storm at sea, with ships in the offing trying to make the harbour. The picture has rather blackened with time, but the dash of the waves is excellently rendered. A still finer Ruysdael is placed below in the North Court. It is a landscape. In the middle distance rises a hill crowned by a castle, and in the foreground a wide stream, its banks clothed on either side by pine trees beautifully painted, rushes by, breaking with force over its rocky bed. Near to this picture is a good Claude, which has been much spoiled by re-painting. Though not done at this painter's best time, it is yet a fine work, and might be set right easily by a good repairer. But to return to the cartoon gallery. The Murillo, placed on the centre screen, is finer than any in the present exhibition at the Academy. The subject is S. Francis kneeling, and holding in his arms the Infant Christ. On the left hand are some cherubs very beautifully handled; one holds in his hand a branch of lilies, emblem of purity; another keeps open the saint's breviary. This is a grand specimen of Murillo's powers, and is not at all black, as are some of his works. The peculiar treatment of the cool grey of the monk's garment should be noticed. Beneath the "Murillo" is a very learned picture by Annibal Caracci. It is one of the best examples of the Eclectic Bolognese School, which, notwithstanding its great efforts after the best of every school, fails, perhaps by it many-sidedness, fully to equal any. This picture should be studied (for it has evidently been painted with much study) and the reason why it fails to bear off the palm of superior excellence inquired into. The drawing throughout is most beautiful, and the composition graceful and complete. Venus is looking at herself in a mirror held for her by a little Cupid, while two of the Graces are arranging her hair. The action of the nymph who is braiding the golden locks of the goddess is very lovely. Several beautiful little Cupids also assist at the toilet. Next to the Caracci is a remarkable Rembrandt, called "Lucretia." The painter has succeeded, as he always does, in producing a noble work, by his colour. Observe particularly the rich golden drapery of the dress, and the masterly painting of the white round the opening of the bodice. It is in the spiritual and mental side of the portrait in which the material and phlegmatic Dutchman is unsuccessful. Who would take that face to represent the noble Roman matron? As a piece of painting, it is indeed very perfect, but as a piece of æsthetic excellence it is devoid of soul, and nothing less than a failure. As a pendant to this hangs one of the best of the Guidos here, "S. Sebastian," full of life and vigour, with almost a boy's face. The unpleasant tone of some of this painter's works, produced no doubt by the showing through of the terre-verte grounds he laid in for his flesh, called his silver tone, is not visible in this picture. It is, however, very apparent in some other works by him in this gallery. On the opposite side of the screen are placed two fine works by Paul Veronese; one, a Venus and Cupid, with the drapery most elaborately finished; the other, a saint asleep on a marble seat, with two angels in the air bearing a cross towards her. The action of the saint is very graceful and elegant, but the beautiful tones of colour which we know must be there are invisible in consequence of the exceedingly dirty state of the picture. The noble Vandyke, "The Entombment," has been much injured by a thick coating of nasty yellow varnish, besides which a foot of canvas has been added at the top of the picture, greatly deteriorating the composition of the work, and being very injurious to the picture, because, as the repairer was unable to paint like Vandyke, he has been forced to paint out the luminous sky of the painter in order to make it agree with his own muddy enlargement. We entreat the owner to have this defacement removed from the picture, which is really a grand work of art, and to restore the canvas to its original size and shape. The figures of the Virgin and Mary Magdalene holding in their arms the dead Christ are very beautiful; S. John and another woman are kneeling by, while a little child points pitifully to the marks of the nail in the Saviour's hands. Near the Vandyke hangs a curious Jan Steen; the subject is not a pleasant one. As a pendant to it is a picture of "Susannah and the Elders," by Bassano. "The Offerings of the Wise Men," called a Titian, is more probably a Tintoret, or even a Bassano. The grouping and composition are finely managed, and the white horse in the foreground is exceedingly well painted. The Virgin in this picture, though ugly, has a sweet expression of face; on her knee is the Infant Saviour, whose feet one of the wise men approaches to kiss. In the background some camels and negro attendants are introduced. The blackness of this picture is partly attributable to age and ill-treatment, through which, though, the fine Venetian method is apparent. In the room where Lord Westminster's pictures are placed, are some fine Watteaus also belonging to this collection; they are of a larger size than this artist usually painted, and considered very fine specimens of his art. There is also a beautiful little landscape, by Poussin, and a good por-

trait of a lady, by Rubens, more like Vandyke in manner. Below, in one of the courts, amongst other pictures is a work by Stothard, illustrating part of the Allegro. It is painted with much grace and elegance and true delicacy of feeling. The girl is such a sweet and maidenly representation of gaiety, and though the drawing is deficient, the sentiment is very beautifully given. Some pictures, said to be by Wilson, are evidently either inferior copies or spurious works. In conclusion, we must beg our readers to take an early opportunity of visiting this collection, in which there are many good pictures besides those we have mentioned, for it is chiefly by the careful study of the old masters that we arrive at a just and due appreciation of the beautiful in art.

LIMES AND CEMENTS.

LIEUT.-COL. SCOTT, R.E., delivered the first of a course of four lectures on limes and cements before the Architectural Association on Monday evening last. The hall was full. Mr. T. H. Watson, President of the Association, introduced the lecturer.

Lieut.-Col. Scott commenced by observing that the subject of limes and cements was one which awakened very little interest amongst workmen, and met probably as little attention from those whose task it was to direct the building of works. Mortar-making was generally given over to the labourer, who compounded it pretty much according to his own fancy; his first desire being to save himself as much trouble as possible, his second to satisfy the bricklayer or mason who had to use his preparation. A strange confusion had hence arisen as to what really constitutes the right proportions of sand and lime to use in preparing a given quantity of mortar. The mason or bricklayer mixed the ingredients in that proportion in which he could use them most readily, but it by no means followed that what was most convenient to him was most suitable to the work he had to perform. The different kinds of lime in use were greatly dissimilar in many respects. The white chalk, as far as building purposes were concerned, yielded a lime very much inferior to that which was yielded by the lower chalk limestones. The latter were hardly worked at all in this country from the prevailing ignorance concerning their utility. At the risk of being charged with egotism, he must here refer to instances he had had brought under his own notice, in which the ignorance of limestones and limes had been more or less displayed. When he was a very young man he happened to be employed at Gibraltar; amongst other duties one was to superintend the construction of a revetement wall. The wall in front of which the men under his orders were building was an old Spanish wall which supported a large quantity of sand, and in making the excavation in order to put in the foundation they came upon a bed of hard shale. On a Saturday evening he left this shale in a firm, solid condition, and on the Monday following it had assumed a liquid form. It let out the sand, and the whole mass falling very nearly buried the men beneath it. What could have caused this change was the question naturally asked. It was only to be traced to the presence of a small quantity of sulphuret of iron which had attracted oxygen from the atmosphere. The curious part was that at that time they were bringing their cement from England in order to put it in this foundation, whilst these deliquescing stones which they were excavating formed, when properly prepared, quite as good a cement as that which was being imported. The captain associated with him in this work was a practical builder, and used to apply this test to the cement in ordinary use: he would thrust his hand into a barrel, and if the cement felt warm it was good, but if cold, he usually concluded that it had been ruined in the transfer to Gibraltar. The fact of its being warm was a proof that it had not been quite spoiled—that was all. Some time after, at Plymouth, he found other beds of lime, which gave a capital hydraulic lime. Whilst experimenting on these stones he found a curious effect produced by a dull fire; he was at a loss to understand it, but he found that the lime, instead of slaking and heating as it should have done, set into a solid hard mass when ground to a powder and mixed with water. He consulted Dr. Faraday respecting this, and they came to the conclusion that the change was due to the formation of some form of "subcarbonate of lime." Subsequently it turned out that the action was due to the presence of a small quantity of the sulphate of lime which had been formed from the sulphuret of iron in the coal. When he mentioned this to Dr. Miller (his master in chemistry), that gentleman could hardly believe it possible that lime could have been used for 4,000 years, and such a simple fact never before have been discovered. A little later he had to visit Barrow, which has a celebrated lias quarry. The limestone there occurred in several layers varying from a foot to 5 or 6in. in thickness, with considerable bands of clay between them. They varied much in composition. Some of them had more clay in them than others, and these were not very readily slaked when dealt with as mortar, and the consequence was that these beds were looked upon rather as an injury than otherwise to the other lime which was made. These were called Rummel beds by those using them, whilst another bed was termed "good for nothing," its supposed quality being thereby indicated. From the outside of their best stones the men cut off chippings, which were thrown back into the pit. If they wanted ground lime their practice was to grind up the best lump-lime they had; but he pointed out to them that they would make better ground lime if they mixed together the three kinds of lime indicated, viz., the "Rummel," the "good for nothing," and the "Slavin" beds, and was at last successful in persuading them to adopt this plan. One fact in connection with this incident ought to be mentioned, to the honour of the Messrs. Ellis' the owners of the works. They wrote some time after to tell him that his suggestion would turn out much to their advantage, and that as a token of their gratitude they proposed to give him a shilling per ton for seven years. This course had been pursued, the quantity had been continually increasing, and all he regretted was that his seven years expired next Christmas. He had seen another curious mistake with reference to the use of lime in London. He imagined he had seen something very like lias lime or grey lime thrown into the Serpentine for purposes of purification. He was certain, however, that six years ago large quantities of grey lime were thrown into the Thames during a very hot summer for similar purposes. One of the grey lime manufacturers told him he was supplying a large quantity for the Thames, and on being asked why the authorities did not get the white chalk lime from Gravesend, the reply was, "That is their look-out; my business is to sell lime, not to teach my employers chemistry." By using grey lime 20 per cent. was wasted, and in addition the authorities paid something like 2s. a yard more for it. Having given these examples of the ignorance displayed by those using lime and cements, the lecturer proceeded to speak of substances which were concerned in limes and cements, and the origin of those substances. He exhibited to a diagram, on which were mentioned the substances chiefly found in hydraulic and common limes. Without going into the geology of the earth's crust, but taking granite as a sort of starting-point, he pointed out that acids would decompose substances such as were contained in granite. The whole, indeed, of the substances which were found in the older beds of the earth consisted principally of silicates of lime, alumina, iron, with some alkalies. These silicates were decomposed by acids. Rain found carbonic acid in the atmosphere, and, charged with this carbonic acid, decomposed a silicate of lime, and as a result a carbonate of lime was formed and the silex set free. These were washed down by rivers, and the grosser portions were obtained as sand, a great deal was carried down as carbonate of lime in suspension, and a portion also was brought into solution and carried into the sea. If the carbonate of lime was deposited without foreign admixture and the deposit subjected to heat, a crystalline limestone was obtained; if clay was deposited with the carbonate of lime, a hydraulic limestone might be the result. Speaking of the portion in solution, the lecturer said that a part flowed into the ocean, and there underwent a marked change, being dealt with by organic life. Of the portion carried down in suspension the quantities were really enormous. The Ganges, for instance carried down 500,000,000 tons per year; the Mississippi, 300,000,000 tons per year; the Irawaddy 100,000,000. The whole of Holland was composed of matter in fine suspension which had been carried down from the Rhine. If they came to the chemical deposits as contra-distinguished from such deposits as had been held in suspension, and took carbonate of lime as an example, they found that at Carlsbad there was a spring of water issuing from the earth charged with carbonate of lime, and when some of the carbonic acid evaporated, there was enough carbonate of lime deposited to form large beds and be used for ornaments. The like was also to be seen in Tuscany, and in various parts of Asia Minor, particularly at Smyrna. At Gottingen there was a stream of water used for turning a mill, which so filled up its channels that they had constantly to clear out the deposit. Near Rome, also, examples of the same sort existed. The matter brought down in solution was deposited by a chemical process, either by evaporation or the escape of carbonic acid gas, which held it in solution. He would now say a few words on the effect which organic life had upon carbonate of lime and silicic acid in solution. One part of carbonate of lime was soluble in 10,600 parts of water, and we might assume that sea-water contained about one-ten thousandth part of its weight of carbonate of lime. An immense quantity of this carbonate of lime was taken up by oysters, corals, animalcules, and other living organisms. It was common to talk of a man as "drinking like a fish," but to say "drinking like an oyster" was perhaps more expressive. Supposing they were to take a man 75 years of age, put him into a press and squeeze him out, there would be obtained from him 45lbs. of solid matter, and 5¼ pails of water. A man in the course of 75 years drank as much as a thousand times his weight of water; but an oyster, supposing that it could extract from sea-water as it passed through its stomach every particle of carbonate of lime which the water had in solution, would pass through its body something like 50,000 times its weight; and yet, notwithstanding this, the water flowed down on the Rhine contained sufficient carbonate of lime in solution to supply shells for 300,000,000,000 of oysters. But what the oyster would do in this way was nothing to what the coral was capable of doing. After speaking of the use of oyster shells and coral-line limestones for lime, the lecturer proceeded to remark that carbonate of magnesia was also dissolved by water, but was not so soluble as carbonate of lime. There was very little of this found in animals, but it was abundantly taken up by sea-plants. As carbonate of magnesia was taken up by sea-plants, and by animlas, a tendency to the separation of these two substances ensued. Turning to the chemistry of his subject, the speaker first dealt with carbonate of lime, which, he said, consisted of lime and carbonic acid gas. If he put carbonate of lime into a fire and burnt it, the carbonic acid gas was driven off, and lime remained, and if he put carbonate of lime into a vessel and treated it with acid, carbonic acid would be given off. In this case they would not have lime remaining, but a substance derived from the muriatic acid, hydrochloric acid, and lime. The lime obtained by burning was a white substance which phosphoresces under heat, and which when treated with water, underwent a violent change. When the hydrate of lime formed by treating the lime was mixed with sand, made up into mortar, and then exposed to the atmosphere, the substance slowly returned to its original condition. One part of the hydrate of lime was soluble in 800 parts of water. The carbonic acid gas of the atmosphere was small in quantity, and could never penetrate to a great distance below the surface, the consequence being that they could never get a very good result out of pure lime, such as could be obtained by burning white chalk. Many persons supposed that mountain limestone would give a very good lime, and in some senses it would do this. It was a good lime for the smelter, the candle-maker, and the soap-boiler, but it was not a good lime for the builder. Alberti, the architect, who had written much on the subject of limes, asserted that he had seen lime more than 500 years old, which had been found in a pit, and which even after that period was well tempered. Dr. John, a German chemist, found at Landsberg, in a pit at the basement of the castle of that name, lime which had been there 300 years, and which was used again in rebuilding the castle. It must be clear that if lime could remain in that condition without undergoing any change if protected from the atmosphere, they would not get any very good result out of it. As long as hydrate of lime remained wet, it was simply a pulp or paste; when it became dry it was little better than dust. Carbonate of magnesia when burnt yielded magnesia, which was not so soluble as

hydrate of lime. A hydrate of magnesia was soluble in 5,000 parts of water, as compared with 800 parts of hydrate of lime. The former had been used as a hydraulic lime in Madras and elsewhere. When they got substances with the lime, such as silex or clay, they found a different set of reactions took place, and were then no longer dependent upon the carbonic acid of the atmosphere for setting properties. Supposing they put silex and lime together, and heated them, a change took place in the former, and from being a substance very insoluble in acids, it became gelatinous, and altogether altered in character. The lecturer here showed a specimen of good grey chalk lime, which had been treated with acid. If, he said, his hearers examined the residue at the bottom of the vessel, after the lime was dissolved, they would find a somewhat gelatinous mass. This was the silex. When they mixed the grey lime with water and made it into a paste, the silex and the lime formed, together with the water, a hydrated silicate of lime. Here then they had a substance which would set without the influence of the atmosphere. Such a substance as this would not have remained like that found at the castle of Landsberg. It would have hardened into a solid mass. It was only such a lime as this as was fit for heavy masonry, or any exposure to damp or wet. If they took lime and pure silex and treated them in this way after burning them together, they did not get a substance which set quickly when water was added, and the whole was made into a paste, but if they got iron or potash and soda present, they would find that quicker action took place. Silex was, in fact, a substance which combined more readily with several bases than with one. Roman cement set quickly for this very reason. As regards sulphate of lime, the lecturer said that one part was soluble in 500 parts of water. It was, therefore, manifest that this was a substance still less able to stand the action of wet than pure lime. Good use, however, might be made of it for inside work. Sulphate of lime contained too within itself the power of setting. When exposed to the action of heat, it lost a portion of its water. If the whole of the water were driven off, it did not set rapidly again; but with three parts driven off, then, when mixed with a fresh amount of water, it rapidly passed into a solid state, and combined with the water to form the hydrated sulphate of lime. It could only be used for plastering and inside work. The lecturer here made a few observations relative to the action of sulphate of lime in controling the action of lime. If water were added to quicklime, the quicklime rapidly fell away to a fine powder. If they took the lime and impregnated it thoroughly with sulphate of lime, then they would find that it would no longer undergo the slaking action. What the theory of the thing might be one could hardly say with any certainty. In concluding this portion of his subject, the lecturer said he had dealt with three different classes of subjects. First of all there was the pure lime, the oxide of calcium, which combined with water and made a soluble substance, and which could only be hardened thoroughly by the action of the carbonic acid of the atmosphere, which never penetrated it to a great distance. Next, the silicate of lime, which might or might not be mixed with iron, alumina, magnesia, and so on, which had the power of combining with water, and by degrees set into a hardened mass; but this rarely took place with very great rapidity, unless large quantities of such substances as potash, soda, and iron were present. The water had to dissolve by degrees particle after particle, so as to bring it into close contact with the silicic acid. Silex and lime did not enter into a silicate form in the burning of limestones, but only approximated to it until water was added. Then they came to the third class—the sulphate of lime, which was totally unfitted for anything but inside use. He would now say a few words on the question of chemical equivalents. After alluding to the symbols in common use to denominate different substances, as appeared on a diagram, the speaker said that the first point to be remembered was that wherever they found such a substance as lime, the proportion of oxygen and calcium in it always was constant. Next, when they had found the proportion in which oxygen would unite with calcium and the proportion in which oxygen would unite with hydrogen and combine with magnesia, they know the proportion in which oxygen would combine with any other substance whatever. Again, when they had found the proportions in which, for instance, one substance mentioned on the diagram (sulphur) would combine with three parts of oxygen, and also found how oxygen would combine with calcium, they would know the proportion in which an oxide of calcium would combine with sulphuric acid. Referring again to the diagram, the lecturer said that the various numbers on it were so far arbitrary as this: they assumed oxygen to be eight, but they might as well assume it to be any other number except for facility of calculation. This gave the symbol for hydrogen as one, the result being that the chemical equivalent of water was nine. If he put a dose of water, nine parts by weight, to a dose of oxide of calcium in 28 parts by weight, the two would combine to form 37 parts of the hydrate of lime. If he took 40 parts by weight of sulphuric acid, they would unite exactly with 28 parts of lime, and so on. The symbols not only represented what were component substances but also the actual quantities in which they combined. He had divided them into two classes: substances primary and secondary. As respects the question of mortars, he would say that when lime and silex together were exposed to the fire, great heat must be applied to fuse them. Supposing they put in a little potash or soda, then they fused readily. It was really another instance of what he had before said—that silex would combine much more readily with several bases than with one. He was now speaking with reference to the action of heat upon it. In those cases where lime and silex were found together, the action was not so ready as when there were several bases. Roman cement stone, for instance, had a very large quantity of peroxide of iron, and set with great rapidity; also, if Roman cement were burned at a high temperature, fusion was readily produced. Referring to another diagram, the lecturer was able with its assistance to show the proportions of clay in limestone as found at some quarry works near Bridgwater. In some beds it was as high as 25·55, in others as low as 11·95. If these beds were all burnt together some of them would be overburnt, and some underburnt. The quarrymen took the lower beds out (those that contained 25·55 of clay) and burnt them for cements. The others were burnt for lime, and as lime sent into the market. In conclusion, Lieut.-Col. Scott stated he had consented to deliver this course of lectures solely with the idea of helping the younger members of the Association, and principally at the request of Mr. Redgrave. Some chemical experiments were then made in illustration of the lecturer's remarks.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

DR. ZERFFI delivered the seventeenth lecture of this course on Tuesday afternoon last, in the Lecture Theatre, South Kensington Museum. The lecturer, in introducing the subject of Greek furniture, observed that whilst our own times were distinguished for the productions of tektonic art, Greece had been altogether monumental in her tendencies, and had cultivated, with special preference, stone and marble work. The principles of furniture construction are, to a certain extent, identical with those of architektonic, but there was naturally some difference, as the one had to deal with movable objects made of light materials, whilst the other treated hard materials and constructed immovable monuments. Wood had been the principal primitive element of all products of construction, just as clay had served in ceramic art and sculpture. In the construction of furniture, the two conflicting forces, the static and the dynamic, must be clearly united for a certain purpose. The properties of the wood or other material to be used must be carefully studied, and its fitness either to support or to be supported considered. Modern furniture, more especially that of French pattern, was often badly made, the wood being curved into ornamental forms without regard to the fibres, &c., thus causing it to snap. We might learn from Greeks, Egyptians, and even from the Chinese, how to bend wood artificially when still filled with sap, so as to form solid curves. The furniture of the Greeks had consisted of (1) chairs; (2) couches, which also served as beds; (3) tables; and (4) chests. The decoration resembled that on the vases and on dresses. Much metal and ivory was also used. The most important piece of furniture was the *thronos* or *klismos*—the easy chair. The legs, arms, and backs of these were ornamented with animal forms, amongst which the sphinx, lion, leopard or tiger were the principal. These couches were at first simple in form, but subsequently they were decorated; they were also covered with carpets, mattresses, and round or square cushions. As the Greeks wrote and took their meals in a reclining posture, their tables were very low. This article of furniture was found in great variety. The legs were treated with great care, and generally carved to imitate those of animals. In form these tables were usually square. In Greek tektonic art four distinct styles, representing periods of development, might be traced: (1) the Archaic, characterised by rough and architectural forms; (2) the Early Doric, corresponding to the time of the introduction of the wheel into pottery, after which the wheel was also used for turning; a great resemblance was to be observed in the products of the two different materials, the circular vase form in the legs of articles of furniture having been most prevalent; (3) the elegant or Ionic, during the time of the tyrants (560—500 B.C.), was distinguished by the introduction of metal, the use of which in household furniture enabled the artist to combine great elegance, lightness, and ornamentation with durability and excellence of pattern; (4) the finished Doric-Ionic, or, more properly speaking, Attic style, during which the old motives were taken up in new forms. With sculpture a reaction against metal work had set in, and certain articles became monumental again. Candelabra, thrones, vases, and tripods, were made of marble and ivory. A fifth period, the Macedonian, could hardly be said to have produced a Greek style, as it was entirely characterised by Asiatic motives. It was distinguished by great luxury; the couches were covered with purple, and constructed of gold and silver. Golden arbours, baldachins, &c., were also made, all in the Assyrian style. Referring to the every-day life of the Greeks, Dr. Zerffi observed that water-clocks and sundials were used to measure time; the toys for children, many of their games, &c., were almost identical with those of our own times, and they possessed a great variety of musical instruments. As in their poetry and philosophy, he continued, so also in everything else, the Greeks were animated and guided by an unfettered love for beauty and freedom. Their architects regulated the monumental enterprises of the ancient Asiatic world, and produced real works of art. Their sculptors, in perfect accordance with the general laws of gradual development, were not satisfied with merely reproducing inert matter, but from contemplating the universe had turned to the consideration of themselves. Prior to becoming metaphysicians they had studied anatomy, and before occupying themselves with psychology they had made themselves acquainted with physiology. In considering their sculpture we found that the Greeks had made a progressive step in the development of humanity. The architect had to deal with dead matter, and could use it only to express geometrical forms and truths. He could appeal to us through symmetry and proportion only; his language was monumental, expressing always one idea. The sculptor went farther; he imitated the highest power of creation in not only producing a form but also in inspiring it with an idea. He did not satisfy our want of shelter, but elevated our feelings to seek a mental occupation when under shelter. He did not reproduce an inert mountain, or a cave, but human beings with all their passions and feelings. Contrasting in this respect with the Orientals, who had never embraced Nature with a free consciousness, the Greeks had freed themselves from all fetters, and became by degrees capable of reproducing the human form in all its genuine beauty. They had done this after long study, and after nearly two centuries' practice in their gymnasia, during which period they had admired the beauty of the human form with the greatest fervour. The basis of their sculpture was the natural form of man, but the endowment of that form with an idea had been the essential point. The Greeks first studied the reality before they attempted to imitate it. Art was the echo of reality—at first a slavish echo, but by degrees a self-conscious reproduction of that reality with a spirit of its own, the idea of the artist. It then passed from the stage of imitation into that of original creation. The first Greek sculptors, like those of Italy in the Middle Ages, had produced close imitations of Nature. Thus the works of Aristokles, Onatos, Kanchos, Pythagoras of Rhegium, Kalamis, and Ageladas, were analogous to those of Verocchio, Pollaiolo, Ghirlandajo, Fra Filippo, and even Perugino. Just, however, as in Italy these were succeeded by Leonardo da

Vinci, Michael Angelo, and Raphael, the early Greek sculptors were followed by Myron, Polykletes, and Phidias. Naturalism was the first step in art, but its climax was idealisation. In every human creature something beautiful was to be found. To generalise these individual elements of beauty in one form was the aim of the great masters. Supposing that a young artist saw a beautiful being, he would not only be struck by the beauty in detail, but would experience a feeling of delight in general. He would afterwards analyse that beauty, would recollect that the eyes would become dim, the cheeks hollow, and the mouth lose its freshness. A melancholy feeling would overcome him; a struggle between despair and hope would ensue at the thought that such forms should pass away—hope that he might be able to fix for ever in a lasting form the beautiful image he had seen. If in representing such a being the artist omitted all that was perishable, and reflected only that which was eternal, he would produce a real work of art. This did not mean that the artist was altogether to lose himself in mere generalisations, so as to give no individuality to his sculptures; but he had to transport his figures to those pure heights of ideal generalisation, in which pride, majesty, love, force, war, &c., might be recognised as general ideas in idealised types. It was in this that the Greeks had excelled. They raised their productions to ideal types, in which not only certain general forms, but also certain general characteristics of humanity were reproduced with real truthfulness. Thus in Zeus we saw not only the beauty of venerable old age, but recognised the highest wisdom and power. In looking at some of the sculptures before us (those of the Temple of Minerva at Athens prior to its destruction by Xerxes) we should see that they had the forms of Assyrian and Egyptian divinities, if we excepted the fact that the anatomy was much improved in some of the figures, though even in these there was still much stiffness in the positions of the hands and legs. The historical periods into which we might group Greek sculpture, to enable us more comprehensively to study its history, were the following:—First period, from the eighth century B.C. to the Persian wars (470 B.C.) Second period, from Kimon to the conclusion of the Peloponnesian war (470—400 B.C.) Third period, from the delivery of Athens to the death of Alexander the Great (400—323 B.C.) Fourth period, from the death of Alexander the Great to the conquest of Greece by the Romans (323—146 B.C.) Greek sculpture had taken its origin in Eastern art. This was proved by the Iliad of Homer. The descriptions of beautiful carriages, richly-adorned couches, stately thrones, and of weapons, shields, and helmets of exquisite workmanship found in that poem, almost led us to think we must be reading Indian or Assyrian works. There could be no doubt that before the introduction of sculpture, metalloteknic must have been developed to a great extent. Homer could never have given the minute description of the shield of Achilles had not some such work existed. From the seventh to the second century B.C. we had a progressive history of Greek sculpture before us, with dates, names of artists, and numerous examples. A consideration of these will form the subject of the next two lectures.

BUILDING NEWS SKETCH BOOK.—LIX.

THE CHAIN GATE AND COMMON HALL, WELLS.

THE accompanying view of these interesting relics of Mediæval art is taken from the measured geometrical elevations and plans sketched on the spot by A. W. Pugin, and published by T. L. Walker, which, although an excellent and practical work, seems to want a perspective view of the buildings or a connected elevation, including that admirable little oriel window in the end elevation of the vicar's dwelling house, which, as restored by Pugin, with the additional mullion, is well worthy of notice.

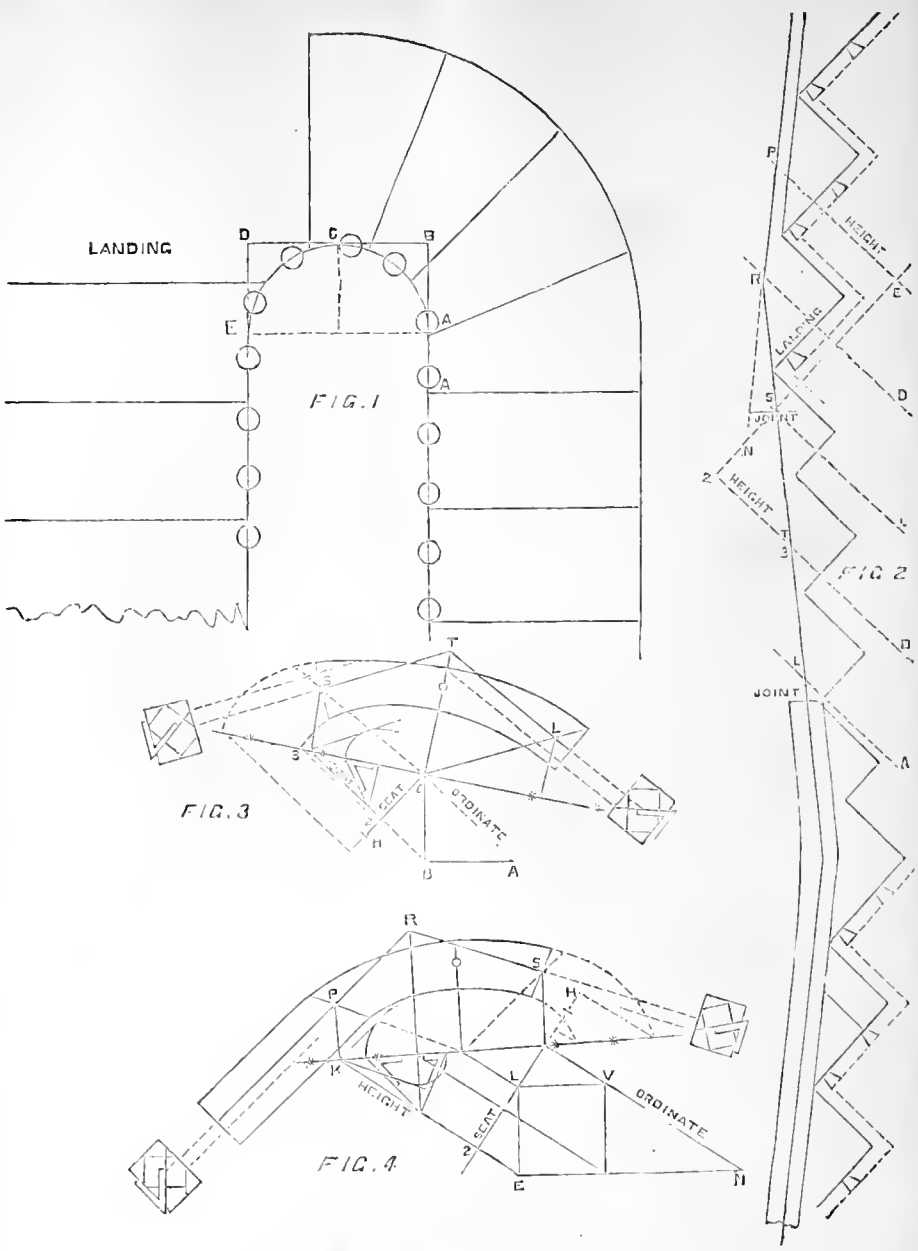
The other parts of the structure have been added to and altered at different dates. The original hall was commenced in the fourteenth century. The thick mullioned window in the centre of the drawing is of much earlier date than the others; the large oriel window over the gateway to the close must have been inserted after the buildings were completed, the buttress being cut away to receive it.

There is a quaint irregularity and pungency about these time-honoured remains, which, apart from their antiquarian interest, have claims upon us in an artistic sense, which we should do well to study.

The effect of broken wall surface, of oddly placed buttress, or sudden recess, is often a refreshing source of pleasure, contrasting well with the nicely balanced symmetry of other portions.

The drawing is intended to be "architecturesque" rather than "picturesque." Fidelity and accuracy being really more important than chiaroscuro in such a case as this, even at the sacrifice of force and depth of expression.

W. H. LOCKWOOD.



NEW ELEMENTS OF HAND-RAILING.—PLATE XXI.

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page* 86.)

PLATE 21.—CONSTRUCTION OF WREATH FOR STAIRS HAVING FOUR WINDERS, QUARTER LANDING, AND SQUARE STEPS.

FIG. 1 exhibits the ground plan. The centre line of rail enclosed by tangents A, B, C, D, E. These are unfolded at

Fig. 2. The letters along margin correspond with those on plan. Let underside of rail rest on corners of square steps. Set off half its thickness. Draw upper part to cut R. This is a fixed point, and stands over D on plan. Draw pitch over winders, say through L. This shows that the upper part of wreath forms its own ramp. Two moulds will be required. Find heights by drawing through joint S, cutting at E and 2, which gives E P as height for upper part, and 2 3 for half the height of lower part.

Mould for this is given at Fig. 3. Let A B C equal corresponding letters on plan. Join A C ordinate. Draw from B parallel with it. Make seat square with it. Let 2 3 the height, equal that on right having corresponding figures. Join 3 C extended. This is pitch and major axis.

Next find points of elliptic curves on pitch by making C H equal C B. This done, set off on each side of H half width of rail. Then square up to cut the pitch.

The drawing is now ready for the mould. The tangents L T and T S being equal, one bevel answers both joints. See that L T S agree with pitches on the right, where similar letters are shown.

Fig. 4 is the mould for upper part of wreath. Let square equal one of those on plan. Extend side E N. Let this equal E N, Fig. 2. Join N V ordinate. Draw from other three corners of square parallels with ordinate. Make the seat square with it. Let the height 2 K equal that of E P on right. Draw pitch from K, through intersection of seat and ordinate. Find elliptic curves on pitch by making L H equal L V. The dotted lines that are parallel with ordinate give the points. The drawing is now ready to lay board on for mould, it being struck with a string.

Tangents P, R, S must agree with the pitches on Fig 2 having similar letters.

Square sections show joints and application of bevels.

It will be observed that the square steps and winders at Fig. 2 stand in the same positions as those on tangent lines of plan.

* This series of articles is a reproduction of ROBERT RIDDELL's work on the subject, published in Philadelphia, and by Trübner and Co., London.

DECORATIVE PROCESSES.

By "An Experienced Workman."

(*Continued from page* 92.)

IN our last we described the process of over-combing oak. A very excellent machine or roller has been invented by Mr. W. Jones, grainer to the trade, of 4, Walnut-street, Hulme, Manchester, of very simple construction, but which performs its work most admirably. Machines for graining ordinary woodwork are, as a rule, complete failures, and, like patent medicines, are guaranteed to do too much—and of course do not do it. Mr. Jones's invention differs from all others in the fact that it only professes to assist the grainer in such parts as may be accomplished by mechanical means, and this purpose it effects in the most complete and efficient manner possible. Its object and purpose is to dispense with the process of over-combing as before described; and this is accomplished by an exceedingly simple arrangement, which deposits the colour upon the work in short bits, in exact imitation of the pores or grain of oak, and, in fact, of any wood which has these pores as a distinctive feature. This invention consists of a wooden roller about $\frac{3}{4}$ of an inch in diameter, and of various sizes, from $\frac{1}{2}$ an inch to 3in. in width; through the centre of this cylinder an iron core is fixed having projecting pins at each side, which fit into an iron handle formed by a half-circle of thick wire bent close together to form the handle, and opened out at the other end to clip the roller and fit upon the projecting pins, and upon which pins the spring of the wire is sufficient to keep the whole in its place. This is simply the framework of the roller. The roller is now clothed with circular discs of sheet-zinc, having notches cut in their edges at irregular distances; these discs are about 1$\frac{1}{2}$in. in diameter, having a hole in the centre cut out to fit upon the wooden core or cylinder; this hole is made a trifle larger than the cylinder, in order that the discs may have a little play and so accommodate themselves to the slight inequalities of the surface of ordinary woodwork; this is a very nice arrangement, well wrought out, without which the tool would be comparatively useless. Another advantage consequent upon this arrangement is that the play given allows the discs to turn round independently of each other, and so the notches in the edges are constantly changing their relations towards each other, and thus variety is secured; this completes the roller. The method of using this tool is as follows:—The groundwork is prepared and figured in exactly the same manner as before described for the over-combing process, and when this is dry it is ready for the roller. The colour to be used on the roller must be mixed much thicker than the ordinary graining colour, and will require to be megilped either with wax or lime-water. A brush or feeder is required to supply the roller with colour as it revolves. This brush will require to be flat, something like a large hog-hair mottler; or a large sash-tool may be flattened so as to answer the purpose. The roller is held in the right hand, and the feeding brush in the left hand; this brush, containing the graining colour is then placed or held firmly upon the upper side of the roller, and inclining to the back part of the same in such a manner as to insure that every one of the notched edges of the zinc discs will touch the feeding brush as they revolve; the roller is then placed at the bottom of the panel or other work to be grained, and is then pushed or made to travel upwards or from the operator, and as it moves along it leaves behind it exact imitations of the short bits of grain or pores as seen in the real wood. The roller requires to be used lightly and with little pressure, only just sufficient to keep the roller steady. When the work is rolled the grain will require to be slightly softened with a duster or stiff softener, care being taken to do this always lengthways of the grain, and not across it. The grain may then be broken up and the lights softened, as in the over-combing process.

These rollers are very compact, easy to use, never get out of repair, and there is scarcely any limit to the time they will last in wear; and we have no hesitation in saying that they are the only invention which may be considered of benefit to the grainer, as by their aid he may get over more work in one hour than can be done with the comb in ten hours; and thus time is saved and cost reduced. The pores or porous grain seen in baywood, mahogany, teakwood, walnut, and rosewood may be admirably imitated with these rollers; but all soft woods, which, as a rule, are grained in distemper, will require to be once varnished previous to being rolled, as of course the grain will wipe off those places on which it is not required much better than upon the distemper unvarnished.

The roller principle seems to be "the idea" in all inventions for graining. A patent was taken out some twenty years ago by Kershaw & Bellamy, for imitating the grain of various woods by means of a roller and strips of leather cut to the required patterns. The leather of which these are made is thick hide, prepared for the purpose in a certain manner. On one side of these the pattern is sketched, and then the ground is cut away to a certain depth, just as a block cutter would do for printing. In some cases the strip of leather is made fast to the roller, and only just covers it; in other cases the leather will be three or four times the circumference of the roller, and of course these are only secured at one end. This roller is simply a metal cylinder with a centre pin or axle, upon which a handle is fixed; they are made of all sizes and widths, according to the wood to be represented. The *modus operandi* is as follows:—The graining colour, which is mixed with weak beer (*i. e.*, distemper colour), is brushed over the work to be grained, and, while it is wet, the roller, which has previously been damped with a wet chamois leather, is passed over it, and as the roller passes along it takes up the colour in patches of the exact shape of the pattern on the roller used. This may then be softened with the badger's-hair softener, and over-grained. It will be evident that this method of machine graining can have but a limited application on woodwork, inasmuch as however much work may be done with such a machine, each part will be merely a repetition of the pattern upon the roller, thus creating a sameness and monotony of patterns utterly wearisome and devoid of contrast, and consequently of beauty; for although the pattern of one of these rollers may be in itself a faithful copy of some particular piece of beautiful wood, yet the endless repetition of the same produces satiety and positive ugliness, for it is only by an intelligent use of the comparatively plain and the richly marked or figured, that harmony, repose, and beauty, are attained.

The mottle of satinwood, mahogany, Hungarian ash, and birch is very fairly imitated by these rollers, and also the beautiful feathers or curls in Spanish mahogany and satinwood. The mottle of these woods has very little variety; that is to say that the mottle of mahogany and satinwood is, as a rule, so much alike, not as two separate woods alone, but of different pieces of the same wood and tree, that one or two patterns suffice for all; and so this class of woods is peculiarly suitable for adaptation to these machines. But here we come upon a fatal difficulty in connection with this system. For instance, we are about to grain an ordinary door. The colour is rubbed in and the roller is applied at the bottom of the panel; now, these rollers, being five or six inches in diameter, cannot by any possibility touch the bottom of the panel nor the top, in consequence of the moulding on the panel being sunk, so that there will always be a certain space of one or two inches, as the case may be, which must be grained by hand, and pieced up to the machine work. Now this can only be done by a thoroughly skilled workman, and if it is not well done there is a decided botch at top and bottom of the panel; and if this is difficult for a highly-skilled workman to accomplish, how much more difficult for a novice to perform! Master painters in out-of-the-way country places see these machines and think they have nothing to do but set the machine going, and beautiful graining is at once produced. We need scarcely say this is a vain hope, resulting in a miserable failure and waste of time and money. Another objection to this method is the fact that, except the greatest care is taken of the rollers (and what a difficult matter that is!) the leather becomes dry, cracked, and shrivelled up, and so they are useless. It will also be evident to any one who is thoroughly acquainted with the art of graining that these machines occupy so much time in the preparation for work, and entail so much extra labour to piece them out and fill up all that they of necessity leave undone, that a good grainer (and it is only those men who can use them) will not be bothered with them, and will get over three times as much work without them as with them, putting out of the question the fact that the work is better and more pleasing done by hand, having more variety and more character than machine work can possibly have. Several attempts have been made, and even some of them patented, to grain oak by means of similar rollers, and even the choicest of marbles are professed to be done by some machine, but with what success we must perforce allow the unfortunate purchaser himself to find out. One would-be benefactor of his species has been foolish enough to patent a system of imitating oak by means of stencil plates, and wiping the figure out through the interstices cut in them. He then over-combs with vulcanised india-rubber rollers, a plan of working exceedingly dirty and inefficient, having all the defects of the previous systems without any corresponding advantages. Personally, we object *in toto* to the use of these machines, first as being in themselves a delusion and a sham, leading the inexperienced workman into a wrong path, which will and can only produce failure and disappointment and bad work. We still more strongly object to their use on the score of the false teaching such methods inculcate, tending to the destruction of personal effort for improvement, making the student content with what must at last result in a contemptible mediocrity. To us they are merely a miserable attempt to substitute methods of doing what can only be done well by persevering effort and close application and study, for it is quite certain that the student who begins his studies by using the machine will never arrive at any degree of proficiency, but will remain a bungler all his life. The workman who expects to produce good work by their aid will be miserably disappointed; for it is a fact that there is in graining, as in a much higher art, an individuality and peculiarity of style inseparable from each man's work—that is to say, if he is a first-class workman—and it is this character which gives so great a charm to original works of any description. On the other hand, there are plenty of men who are mere copyists, men who, like the parrot, can only repeat certain set forms, and are totally without originality or invention; to such men all systems and methods are alike—they jog on in the one groove all their lives, without talent or ambition to slip out of the beaten track. These are the class of men who patronise these machines, but certainly without benefit to themselves or anybody else.

We have now but to notice briefly the transfer oak process. This process is an adaptation of the process of transferring designs from copper-plates to the biscuit of china and earthenware, as practised in the potteries

But in this process, instead of printing from the copper-plate, a slab or board of real oak is used for that purpose, as thus: A suitable piece or board of oak is prepared in a particular manner, so as to clear out the soft fibre from out the grain or pores. This process at the same time hardens the wood. The wood being now ready, the printing colour is laid upon it and spread evenly. A scraper is then passed over the board, and cleans off all superfluous colour, just as if it were a copper-plate, only in the potteries the pallet knife is used. A particular kind of transfer paper is then laid upon the board, and the whole is passed under padded rollers, and when the paper is taken off, the whole of the pattern of the oak board is printed upon it. This paper may then be cut up into any sizes as may be required, and the grained side placed upon the work to be grained; it is then well rubbed, and after it has stood some time the paper may be washed away with water and a sponge, leaving the whole of the figure and grain of the oak upon the painted wood. By this process we transfer a facsimile of the wood to the painted surface, and if the colour of the ground and the graining colour are properly managed, the work cannot be distinguished from the real wood. The process of printing from the wood was first introduced and patented in France and the United Kingdom by a French firm, and applied to wall papers. They were first introduced into this country some nine or ten years ago. Many attempts have been made by our paper-hanging manufacturers to imitate this manufacture by other means, but none have succeeded so well as Messrs. Heywood, Higginbotam & Co., of Hyde-road, Manchester, who turn out some oaks we prefer to the wood-printed goods. The patent for the transferring from the wood on to the paint work was taken out by a Mr. Dean, who is engaged in the earthenware manufacture, to whom, after seeing the French process, the idea of transfer would be quite natural and easy to carry out. The process is good and thoroughly effective, but the great cost involved must prevent its being used, except for special jobs, and we know of no other wood but oak for which this process is available.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT the ordinary general meeting of this Institute on Monday evening last, Mr. Edward I'Anson, Vice-President, occupied the chair. The minutes of the previous meeting having been read and confirmed, Mr. Robert Walker, of King's Arms Yard, Moorgate-street, was elected an Associate.

Mr. HEBB, Associate, said he should like to call the attention of the Institute to a point of professional practice. Some time ago the Institute issued a memorandum with regard to professional charges, which was supposed to regulate the practice of architects in connection with the Institute; this was as far back as 1862. The resolutions contained in the document referred to were numerous, and embraced nearly all the varieties of practice with which an architect was likely to meet. The point to which he wished to direct the attention of the meeting was the article regarding the remuneration to be paid to an architect for his services in his professional capacity. In the statement of professional practice referred to, this remuneration was fixed at 5 per cent. on the total cost of the works executed; there were, under special circumstances, however, exceptions to this rule, the architect being entitled in some cases to 10 per cent. on the outlay, while in other instances he was to receive less than 5 per cent. At any rate, it seemed to him to have been the intention of the Institute that the minimum charge should be, as a rule, 5 per cent. He would therefore ask whether the attention of the Council had been drawn to the "conditions" which had been issued recently by the Governors of Bridewell and Bethlehem Hospitals, in which their architect's commission was fixed at 2½ per cent. This, it was true, was in addition to a salary. Were the rules which had been framed and issued by the Institute supposed to be binding upon all the members, or were they to be regarded as merely in the light of "recommendations" which the Council desired might be conformed to as much as possible? Any departure from such rules (supposing them to be binding) by one or two members must necessarily be to the damage of the rest of the members, and of the profession at large. But if they were merely "recommendations," they must be looked upon in another light than rules which should govern the conduct of the whole of the members of the Institute. If they were rules to be conformed to by all the members, were they still binding, or were they abrogated by anything which had taken place since 1862?

PROFESSOR KERR thought that, on that occasion, when the Institute had met to hear a paper read, it was out of order for Mr. Hebb to put such a question, interrupting, as it did, the usual course of business.

Mr. SEDDON, hon. sec., said that a similar question had been answered the other day. The clauses of the document referred to by Mr. Hebb were not considered to be *rules*, but merely recommendations which it was desirable that every member of the Institute should adopt.

Mr. NASH, Fellow, did not concur with what Professor Kerr had said, and thought that Mr. Hebb's question was a very reasonable and proper one to ask; and if such a question could not be asked at an ordinary meeting, how or when was it possible for a member of the Institute to direct attention to any subject which he considered to be of importance? The question brought forward by Mr. Hebb was very important, as just now it was of the utmost consequence to have a clear understanding on all points of professional practice. He thought that it might not be altogether amiss if the Council were to reconsider and revise the document referred to, which, nevertheless, he considered a most excellent one. The Bridewell Hospital "conditions," however, did not bear upon the question at all, for the architect to the Governors received a salary, and therefore could not expect to receive 5 per cent. as well.

Mr. BECKETT DENISON, Q.C., then gave a lecture "On The Mathematical Theory of Dome Construction." In the discussion which followed, Messrs. Penrose, Wyatt Papworth, Nash, and Prof. Kerr took part, the general opinion being that Mr. Denison had laid down very valuable rules for mastering the many difficulties and perplexities of dome construction, although Mr. Nash inclined to the opinion that the "practical sagacity of the architect" ought to be more than sufficient to grapple successfully with such difficulties.

Mr. DENISON, in reply, while admitting that "practical sagacity" went a long way with architects, as with other people, pointed out that in previous discussions on dome construction the members had been unable to come to any definite conclusions on the subject, and it was only by mathematics that such conclusions could be arrived at.

The thanks of the meeting were formally tendered to Mr. Denison for his paper, and the meeting adjourned.

ON LONDON AS A FIELD FOR ARCHITECTURAL STUDY.*

(*Continued from page* 96.)

THE fire of London is the great event in the architectural history of our metropolis. The year 1666 lands us, in our study of London, at the commencement of what is the fullest period, the modern epoch, in which we ourselves are living and working. Of course the great change in learning and in art which distinguished the sixteenth century had, ere this date, swept over Great Britain as it did over the rest of Europe, and in this country some part at least of its action was intensified by its being complicated first with a religious and then with a political revolution. Had it not been for the Fire of London many more traces of this gradual change, or of the times which preceded it, would have survived than actually exist, but the fire made a disastrously clean sweep of much that we should have valued now, and left a vast field for Wren's works, which, with those of his successors, constitute a definite London school of architecture. Before the Fire we had Renaissance architects at work here, and the greatest of them, Inigo Jones, has left behind him in the banquetting hall, Whitehall, an excellent specimen of the art of Italy, imported, with but little variation in its details, into this country. This building, like all Jones's work, is well worth study, and though a fragment of a large design, it is very complete in itself, and very full of characteristic points. The super-position of orders commonly to be found in the works of Vignola, and the completely decorative use made of the orders, are characteristic of Italian Renaissance building; so is the very secular quality of the whole design—a quality which you will see it was right it should possess when you recollect that this building was a banquetting hall, and not built as a chapel at all. I suspect, however, notwithstanding his fine simple church in Covent-Garden, that Renaissance art would not have lent itself well to ecclesiastical purposes in Jones's hands any more than it did in the hands of most of his Italian and French contemporaries; and it was reserved for Wren, a man of perhaps greater genius as well as grander opportunities, to mould a very inflexible style—and one associated far more with the recollections of pagan rites or with a pompous ritual than with simplicity in the celebration of Christian worship—to the purposes of the English reformed Church. In Wren we possess an architect of the first rank, distinguished for sound judgment and skill, versatile talents, and real genius. His mind was strongly imbued with the spirit of Gothic, though he did not understand its letter. Such of his works as profess to be Gothic, like the west towers at Westminster, are very defective; but those where he employed his own architecture, but in a Gothic manner, are most delightful. The steeples of the City churches are excellent examples of what I mean, and the best of them—such, for example, as those of Bow Church (Cheapside), S. Bride's, and S. Clement Danes—are excellently well worthy of study. His best churches are worth attention as interiors, on account both of their beauty and their convenience. The most famous are S. Stephen's, Walbrook (noted for good architectural treatment), and S. James's, Piccadilly (for economical arrangement and construction); but almost (if not quite) all of them, are convenient, effective, and excellent for speaking and hearing in. His great work, S. Paul's, I need not, I hope, recommend to you as in its style *a chef d'œuvre*; but I may perhaps be allowed to say a word as to why any great building of the style in which Wren worked ought to be studied by you. There are, I know, some architects and some students who say they only intend to work in a Mediæval style; that the best architects of the Middle Ages knew nothing of the Classical work which had gone before them, and did well without it; and that they hope, by retaining an exclusively Gothic bent of mind, and keeping themselves as free as possible from Classic, to do as well as they. Put boldly, this means that they will emulate not merely the skill but the seclusion of the Mediæval architect. Now I take it this is founded on the radically-defective basis that whereas the architect of the Middle Ages was thoroughly in harmony with his own time, our supposed exclusive Mediævalist would be thoroughly out of harmony with ours. To know nothing of the work of the Romans was the common condition of the country, and the architect shared it. To know something of the work of all past times is—unfortunately, perhaps, but unquestionably—the lot of the nineteenth century, and the architect who would keep abreast of his own day must share that knowledge. But more than this, the works of the Renaissance architects usher in the modern manner, which has never yet been rooted out or supplanted, and which, instead of being combated and contradicted at every step, ought to be understood and kept in mind. It is no more possible to avoid the modern element in the taste, the knowledge, and the requirements of the public, or the modern improvements in building materials, than it is to ignore the nineteenth century in dress, literature, amusements, politics, or any other element of social life. It appears to me, then, that in urging you to examine Wren's works as forming the starting point of modern architecture in London, I am naming a very strong element in the claim which they make upon your attention. Wren's cathedral belongs, however, to the highest category of works which are appealed to as the culminating points in the history of architectural styles, which are matters of national pride, and which are the landmarks of great cities. Far inferior in bulk and in richness to S. Peter's at Rome, and perhaps not so refined in detail, S. Paul's has unquestionably the finer exterior; and though its interior has been surpassed by several similar works, it is yet among the very finest. When you have become familiar with S. Paul's, I would have you visit the model of Wren's original design (which lies, or did lie, in a half-repaired condition at South Kensington), and try to realize from it what the intentions of its gifted author had been as to interior effect. Of Wren's powers as an architect of secular buildings, Greenwich Hospital (a building easily within reach of London) is a noble example, and I recommend this building to your careful study. His other secular works near London are several of them less noteworthy, but I cannot forbear naming Chelsea Hospital as a plain work, full of good sense, simplicity, breadth, and dignity. Wren's followers did not equal their master, and I am not inclined to urge your devoting much attention to the works of Gibbs

* Read before the Architectural Association on Friday, the 27th ult., by Mr. T. ROGER SMITH.

and Hawksmoor, though S. Martin's Church, by the first-named architect, is a building of much merit. A greater architect than either was Vanbrugh, who, I think, has not left any building behind in London.

The latter part of the seventeenth century was distinguished by features worth your notice, and which are to be found in private dwelling-houses. Most of the gabled houses, with overhanging stories and projecting bay and oriel windows — which belonged to the sixteenth century, or, at least, were in the manner of it—have disappeared, or we should, at an earlier stage, have had to notice them; but the style of house which succeeded them is still to be found in the outskirts of London, and in decayed portions of the metropolis itself—large square houses of red brick, often beautifully cut and rubbed; rich overhanging cornices, and high roofs; excellent wrought-iron gates, and finely-carved wood brackets adorn their exteriors, which often also are enriched internally by good chimney-pieces, fine vigorous woodwork in doors, dados, shutters, &c.; and which always boast a roomy hall and staircase, with excellent balustrades. The most beautiful bits of detail in S. Paul's are Gibbons's wood carving, and forged iron grilles of which the smith's name is unknown to me. In many parts of London you may find fragments of wood-carving and wrought-iron not far inferior to those at S. Paul's—certainly quite in the manner of it, and well worthy of being sketched. At Hampstead, Highgate, Wandsworth, and other suburbs, these houses abound; and in London (in such places as Queen's-square, Westminster, and Lincoln's Inn Fields) they still survive. Coming down again, we have the polished and refined work of Sir William Chambers, who in Somerset House produced a building well deserving your study; and after him the buildings (private houses mostly) of the Adams. These houses, weak and poor in other respects, are remarkable for the beauty of their plaster enrichments, and in such places as the Adelphi-terrace you may find houses with ceilings that can hardly be surpassed. Sir John Soane is the next architect of note. His best work, the Bank of England, is one of the buildings which, I think, deserve to be pointed out to your notice. It is entirely destitute of external windows, and lower than all the buildings round it, and yet, though deprived of the two means by which alone an architect generally hopes to produce a commanding effect (height and features), Soane has here produced a building which is pleasing in effect and full of very beautiful detail, and which holds its own among the lofty piles in its neighbourhood. I now come to a period which I look upon with great regret, and should almost have been glad to have avoided mentioning had I seen how to pass it by. It is the Greek, the Anglo-Greek, time I mean, which, commencing at the return of these enterprising travellers Stuart and Revett from Greece, has continued almost to our own day. I have already ventured to give my own opinion of Greek architecture as attempted to be introduced into this country. The Greek revival was a gallant effort nobly made, and deserved success, but it was, I think, impossible for an architecture originated and matured under such very different climatic circumstances to be imported with satisfactory results. The Greek revival was, however, popular for a time, and several opportunities of executing what must be considered Greek buildings were enjoyed in London by the architects of the movement; indeed, they were in this respect more fortunate than their successors in the far more general and more popular Gothic revival have hitherto been. At the outside the difficulty had to be met that most important buildings required in London were of a description of which no examples existed in Greece, and that the amount of external light required to be admitted and of shadow permissible was altogether different. In such structures as the Post-office, the British Museum, London University College, and the National Gallery, we have the results of these conditions. All of them have a forbidding aspect, because what is welcome shade in Greece is cheerless gloom in London; all of them have Greek details, but, in the mass, breathe more or less of the spirit of Roman or Italian composition, and, what is perhaps of most importance, no one of them is enriched with that profusion of good sculpture which is wanted, if I mistake not, in a Greek building in London at least as much as in Greece. For correctness of detail I believe S. Pancras Church in the Euston-road may be safely consulted by you; and for effectiveness I am inclined (though disagreeing, I believe, with general opinion) to recommend the portico to the Euston Station, designed by the late Mr. Hardwick. The Greek revival furnished us with at least two very distinguished architects, Cockerell and Elmes. Of Elmes's work I am not aware whether any specimen exists in London. He died early, leaving his great building, St. George's Hall, Liverpool, incomplete, but having, in designing that structure, gone further in the direction of making Greek architecture available for English wants than any other artist. That building, whenever any of you can visit it, will be sufficient evidence to you that Elmes's death was a great loss to our art. Of Professor Cockerell some here present retain, I doubt not, that affectionate and enthusiastic kind of recollection by which the memory of so accomplished and so kindly a professor is cherished among those who attended his courses. Some of his works in London deserve your especial attention, if you are minded to see what Greek art can do here. His insurance office at the corner of Agar-street is a good specimen; so was the London and Westminster Bank before it was mutilated (I was about to say), at any rate ruined, by the façade being prolonged, and that in the curved line. A very instructive example of Cockerell's work is the building which I think he himself regarded as his best work in London, and which, though not Greek, has so very large an infusion of Greek refinement in it that we may well be justified in taking it as a kind of transitional example between Greek and Italian Renaissance. I refer to the Sun Fire Office, and I do not think that any amount of time or trouble which you may devote to that building will be thrown away. That incongruity between English wants and ancient models still existed, but not in the same degree, when men began to turn to Roman examples; but what was much more to the purpose, the process of adapting the latter to modern requirements, as far as adaptation was necessary, had been already gone through by a race with far higher natural artistic endowments and far better training than our own; and Florence, Genoa, Rome, and Venice, with a host of other Italian cities and towns, were found to teem with examples of modern architecture which had a thoroughly Classical character, and therefore harmonised with the tone of mind that our all but exclusive study of the poets and prose writings of Greece and Rome had rendered very universal among educated Englishmen a generation back; while it had already been shaped to our uses by having been employed for all the purposes which modern European civilisation desires that buildings shall serve. In Italian Renaissance, then, we have a style, or more properly a group of allied styles, introduced by Inigo Jones and Wren, and which never wholly died out, but which was reverted to eagerly in England at the close of the Anglo-Greek period. This style has a strong hold upon London; a very considerable number of good buildings have been erected in it, unfortunately along with many bad ones, and if I mistake not it will continue to be popular for a long time yet. The best examples in London of Anglo-Italian Renaissance yield very little, if at all, to their Italian prototypes, and if you will select them carefully, and will keep to the good ones, you may obtain a very good knowledge of the style without leaving London. I know that the difficulty is great for young students, and even for those who are somewhat advanced (if untravelled), to know what is good, and after some consideration I have thought it better to point out to you as samples a few *men* whose works you may safely trust, and a few buildings which you may well study, than to attempt to analyse a large number of buildings. But you must not suppose that if I name only three or four architects, that their works and the other buildings I happen to mention are the only ones I consider really good. Such selections are necessarily made as specimens only, and inevitably leave many good works by good men quite unnoticed. The late Sir Charles Barry was *facile princeps* among those who have worked in the Renaissance styles in our own time. His best works for our purpose are the Reform Club in Pall Mall, and the Travellers' Club, which adjoins it; and a neighbouring building of great beauty, though to my taste a less perfect model—Bridgwater House. Barry's Treasury buildings in Whitehall may be added to this list, and nothing better in Renaissance architecture in the shape of studied composition and refined detail can possibly be put before you than these four exteriors. The range of Pall Mall clubhouses will yield one or two other fine examples —the Carlton for instance (I believe by Mr. Smirke), which is none the worse for our purpose that it adheres very closely to one of Sansovini's designs at Venice; but while commending these to your notice I cannot but dwell upon the higher value of Barry's works as objects of study. Sir James Pennethorne's Italian works may be named as worth careful attention. I would especially refer to his London University, in Burlington Gardens, and his Museum of Practical Geology. His enlargement of Somerset House, though a very creditable work, does not claim attention in exactly the same way, as it is only the carrying out of an existing design. Among the mansions of the West End there are here and there examples of the style we are considering, which rise well above the general dead level of sordid stucco. As good an instance as any is Mr. Holford's house, in Park-lane, built by Mr. Vulliamy, I believe, and which is a very nice example of an Italian villa or small palazzo transplanted hither. The Marquis of Westminster's incomplete house near it is another good example.

East of Temple Bar we may now and then find, amid a mass of the most regretable lost opportunities, a good example of Renaissance, and there is sufficient in quantity to have enabled London to vie with Venice had our architects only been men half as fit for their opportunities as Wren was for his. Mr. Tanson's Bible Society's House may be named as an honourable exception to the generally disgraceful level of city work; so may some others of his street buildings. Goldsmiths' Hall, by the late Mr. Hardwick, deserves honourable mention as a vigorous and even noble specimen of architecture —perhaps a trifle heavy, but very palatial, and far in advance of most of the halls of the City companies, among which some recent specimens are no improvement on their predecessors. Mr. Gibson's National and Provincial Bank may be named as a good example of the utmost decorative enrichment that can be lavished upon a building. It is a decided success, and will furnish a fund of good detail. Professor Kerr's Insurance Office at the corner of Eastcheap is another successful and well-wrought-out city building of Italian architecture. This list might, with some pains, be extended considerably, but it is hard to keep one's patience when one reflects how easily a long list of costly London buildings which I could only name, did I mention them to you, as *examples of what to avoid* carried out in marble, granite, and freestone, might be made out, and how needless it is that it should be so. London tradesmen and merchants will pay for stone and granite, girders and glass; when will they learn to value genius and taste? When shall we ourselves learn to do our duty to ourselves and our profession? A florid example of the style we are referring to has been recently completed in Sir Digby Wyatt's India Office. I am now referring to the interior, that portion of it which is the work of an architect who professes to practice the Renaissance style. The quadrangle and staircases are well worth attention, as showing the results of a strong love for ornament highly cultivated and freely indulged, though more decorated than is usually either practicable or desirable. The Renaissance style, as you may be aware, penetrated France earlier than or at the same time as England, and certain developments of it are due rather to French than to Italian treatment. Of the best French period, as far as ornament goes—the time of Francis I.—we have, I think, no imitations in London, and yet I can hardly imagine a style better suited to the display of elegant richness in a small frontage than that. The Crystal Palace Renaissance Court contains some fragments of it, and perhaps some of them may stimulate you to seek more familiar acquaintance with it in the Valley of the Loire. The high roofs, tall pilaster-like lines of rustics, and some other features which have been common of late years, are, however, traceable to French influence, but in part of a later period; and such buildings as the Cannon-street and Charing-cross Hotels, by Mr. E. M. Barry, and the large masses of buildings recently erected on the Marquis of Westminster's estate by Mr. Cundy (near the Victoria Station) must be accepted as the best specimens we have of this manner. They are none of them, however, such good specimens of French Renaissance as Sir C. Barry's works were of Italian, being deficient in the refinement and finish of the works of French architects. A house recently built in Park-lane may be, perhaps, recommended to you as a more perfect specimen of this manner, of which there are some other fair examples in the West End of London, such as the Great Western Hotel.

(*To be continued.*)

S. ALBAN'S CHURCH, TATTENHALL, CHESHIRE.

THIS church, consecrated in November last, has with the exception of tower and aisle walls been entirely rebuilt. The space formerly occupied by the old chancel is now included in the nave, and the south aisle has been extended one bay; the original window at east end of same having been re-inserted. A new chancel, organ chamber, and vestry have been added.

The tower is a square embattled structure of stone, built in the reign of Henry VII., and contains a peal of five bells. From the level of the gutter project short grotesque gargoyles; and two empty niches, probably once containing figures of the Virgin Mary and S. Alban, occupy prominent positions above the doorway. The initials R. H. and M. R. D. on shields below the niches have given rise to antiquarian controversies. Inside, the tower is open to the church, but a screen has been fixed under the arch, to conceal the bellringers from the view of the congregation. The tower window is filled with stained glass by Messrs. Lavers, Barraud, & Westlake. The window also at west end of south aisle is filled with stained glass by Messrs. Clayton & Bell.

The nave is divided from aisles by four arches springing from piers with moulded caps. The roof is supported by three principals, which, with the rafters, are of varnished pitch pine. The nave roof has been raised about 10ft. from those of the aisles, and the intermediate walls have been pierced with clerestory windows. The windows of aisles have been thoroughly repaired, and new lead lights inserted. The old box pews have been replaced by open ones, which will accommodate about 500 persons. The whole of the interior walls are of stone. The font and pulpit of stone are special gifts.

The new chancel is well raised, and paved in the centre with encaustic tiles. Preparations have been made for the erection of a reredos. The east window, by Hardman, has been presented as a memorial to the late Rector, and illustrates the Crucifixion and scenes in connection therewith. In a window in the south side of chancel, the stained glass which was formerly in the old east window is replaced. It contains a representation of S. Alban, and the arms of Lord Dudley, who was executed for high treason in the reign of Henry VII., and who held the manor at that time.

The new south porch was the gift of a parishioner, and is framed with strong oak timbers, the beams and verge-boards being carved. The windows have painted glass in them.

The whole of the roofs are covered with green Langdale slates.

The works have been well carried out, at a cost of £3,500, under the direction of Mr. John Douglas, architect, of Chester, by Mr. George Woollam, builder, of Tattenhall.

EXPERIMENTS ON THE OXIDATION OF IRON.*

SOME two years since, Sir Charles Fox inquired of me if I could give him the exact composition of iron rust, viz., the oxidation found on the surface of metallic iron. I replied that it was admitted by all chemists to be the hydrate of the sesquioxide of iron, containing a trace of ammonia; to this he answered, that he had read several books on the subject in which the statements referring to it differed, and from recent observations he had made, he doubted the correctness of the acknowledged composition of iron rust. He further stated that if he took a bar of rusted wrought iron, and put it in violent vibrations, by applying at one end the fall of a hammer, scales would be separated which did not appear to him to be the substance I had described.

This conversation induced me to commence a series of experiments which I shall now detail. I first carefully analysed some specimens of iron rust, which were procured as free as possible from any source of contamination. Thus one of these samples was supplied to me by Sir Charles Fox, as taken from the outside of Conway Bridge, the other secured by myself at Llangollen, North Wales. These specimens gave the following results when submitted to analysis:—

	Conway Bridge.	Llangollen.
Sesquioxide of iron ..	93·094	92·900
Protoxide of iron ..	5·810	6·177
Carbonate of iron ..	0·900	0·617
Silica	0·196	0·121
Ammonia	Trace.	Trace.
Carbonate of lime ..		0·295

These results clearly show the correctness of Sir Charles Fox's foresight, that the composition of the rust of iron is far more complicated than is stated in our text books. Therefore the question may be asked, Is the oxidation of iron due to the direct action of the oxygen of the atmosphere, or to the decomposition of its aqueous vapour; or does the very small quantity of carbonic acid which it contains determine or intensify the oxidation of metallic iron? To reply to it I have made a long series of experiments, extending over two years, and which I hope will throw some light on this very important question.

Perfectly cleaned blades of steel and iron, having a gutta-percha mass at one end, were introduced in tubes which were placed over a mercury trough, and by a current of pure oxygen conducted to the top of the experimental tube, the atmosphere was displaced, and it was then easy to introduce in these tubes traces of moisture, carbonic acid, and ammonia.

After a period of four months the blades of iron so exposed gave the following results:—

Dry oxygen ..	No oxidation.
Damp ,, ..	In three experiments only one blade slightly oxidised.
Dry carbonic acid	No oxidation.
Damp ,,	Slight appearance of a white precipitate of the iron, found to be carbonate of iron. Two only out of six experiments did not give these results.
Dry carbonic acid and oxygen ..	No oxidation.
Damp oxygen and carbonic acid	Oxidation most rapid, a few hours being sufficient. The blade assumed a dark green colour, which then turned brown ochre.
Dry oxygen and ammonia.. ..	No oxidation.
Damp ,, ,, ..	No oxidation.

The above results prove that under the conditions described, pure and dry oxygen does not determine the oxidation of iron, that moist oxygen has only feeble action; dry or moist pure carbonic acid has no action, but that moist oxygen containing traces of carbonic acid acts most rapidly on iron, giving rise to protoxide of iron, then to carbonate of the same oxide, and last to a mixture of saline oxide and hydrate of the sesquioxide of iron.

These facts tend to show that carbonic acid is the agent which determines the oxidation of iron, and justifies me in assuming that it is the presence of carbonic acid in the atmosphere, and not its oxygen or its aqueous vapour, which determines the oxidation of iron in common air. Although this statement may be objected to at first sight, on the ground of the small amount of carbonic acid gas existing in the atmosphere, still we must bear in mind that a piece of iron, when exposed to atmospheric influences, comes in contact with large quantities of carbonic acid during 24 hours.

These results appeared to me so interesting that I decided to institute several series of experiments.

When perfectly clean blades of the best quality of commercial iron are placed in ordinary Manchester water they rust with great facility, but if the water is previously well boiled and deprived of oxygen and carbonic acid, they will not rust for several weeks. Again, if a blade of the same metal is half immersed in a bottle containing equal volumes of pure distilled water and oxygen, that portion dipping in the water becomes rapidly covered with the hydrate of the peroxide of iron, whilst the upper part of the blade remains for weeks unoxidized; but if a blade be placed in a mixture of carbonic acid and oxygen, a very different chemical action ensues, as not only that portion of the blade dipping in the water is rapidly attacked, but the upper part of it immediately shows the result of chemical action, and also the subsequent chemical re-actions are greatly modified by the presence of the carbonic acid. For in this case that portion of the blade is only covered with a film of carbon, together with a dark deposit, composed of carbonate of the protoxide and hydrate of the sesquioxide. The fluid, instead of remaining clear, becomes turbid.

These series of experiments substantiate the interesting fact observed—that carbonic acid promotes oxidation.

A long series of experiments were also made to try and throw some light on the curious fact, first published by Berzelius, subsequently studied by other chemists, and well known to soap and alkali manufacturers, namely, that caustic alkalies prevent the oxidation of iron. My researches can be resumed as follows:—

1st. That the carbonates and bicarbonates of the alkalies possess the same property as their hydrates; and

2nd. That if an iron blade is half immersed in a solution of the above-mentioned carbonates, they exert such a preservative influence on that portion of the bar which is exposed to an atmosphere of common air (oxygen and carbonic acid), that it does not oxidize even after a period of two years.

Similar results were obtained with sea water to which had been added carbonates of potash and soda.

* Read before the Manchester Literary and Philosophical Society, by Prof. F. GRACE CALVERT, Ph.D., F.R.S., &c.

THE SANITARY MEASURES OF THE GOVERNMENT.

SIR C. B. ADDERLEY, M.P., writes as follows to his constituents:—"The work which has now occupied me two years, and during this recess has kept me much away from the country, namely, the Chairmanship of the Royal Sanitary Commission, seems to be approaching a successful end. The report is forthcoming, which gives a history of our confused and multifarious sanitary laws up to the present time, and extensive evidence, oral and written, on the imperfect working of local government—the most vital essence of our national vigour—in most parts of the country. It elaborates, through comment and argument, a complete consolidation into one clear statute all the provisions which in every town and parish of England and Wales, except the Metropolis, are required for the health and social well-being of the community. Mr. Bruce assures me that he and two of his colleagues are now hard at work preparing a bill from these materials; and I hope that, while the better organization of our national defences will be necessarily the main subject of the labours of the approaching session, this great work of domestic reform may find its quiet opportunity. The idea of the one comprehensive Act will be to render uniform, general, and active the powers of local government in every place under the inspection and stimulus of a Central Authority."

NEW BRIDGE AT MALTON.

ON Friday last, the North-Eastern Company completed for traffic a new bridge across the Derwent, connecting their railway system with the town of Malton. The structure is of iron and stone, and has two clear spans of 47ft. each, from massive stone abutments on each side. The roadway is carried on twelve iron box-girders, resting on a row of six iron piles and columns in the centre of the river, the hollow piles having been driven 14ft. into the river bed and then filled up to the socket with concrete. The width of the bridge is 30ft., giving a good roadway and tramway into the town, and two footpaths. The sinking of the cofferdams on each side was of considerable interest. On the North Riding side the place hit the centre of the site of the Roman town, but, singularly, few Roman relics turned up. These were silver and copper coins, which are held by Mr. Charles Cabry, of York, the engineer. At the very bottom the British (supposed) remains were reached, and, together with an enormous number of horns and bones (chiefly of small oxen), one bone skewer and two gold pins were found, which are now held by Mr. Monkman. Relics of later times—one a singular iron axe, in possession of Mr. J. R. Mortimer, of Driffield, and a large silver buckle, held by Mr. Thos. Cabry, the chief engineer—were also found. On the East Riding side there were none but fossil remains, the cofferdam being wholly in the hard Kimmeridge clay. The light appearance of the new bridge gives a greatly-improved approach to Malton, and the work has been carried out, under great difficulties from floods and storm, in a very substantial manner. The construction has been under the superintendance of Mr. Chas. Cabry, of York.

ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETIES.

LIVERPOOL ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETY.—The ninth meeting of this Session was held at the Royal Institution on Wednesday evening. Mr. T. D. Barry and Mr. H. H. Statham read some Notes suggested by recent visits to some of the old English Cathedrals.

THE LEICESTERSHIRE ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETY.—The annual meeting of this society was held on Monday week, in the Town Library, Guildhall, Leicester, the Rev. J. H. Hill, F.S.A., in the chair. Mr. North, the honorary secretary, read a statement of accounts for the past year, showing a balance in favour of the society. He also presented and read the report of the committee for the year 1870.

YORKSHIRE ARCHITECTURAL SOCIETY.—On Tuesday week the general meeting of the members of the Yorkshire Architectural Society was held at the York School of Art, when the Rev. Canon Hey presided. The Rev. G. Rowe, the secretary, read the report:—"The society continues in a flourishing condition, and although the expenses of publication, &c., have this year been heavy, there is still a considerable balance in the hands of the treasurer. The paper on the Rural Deanery of Knaresborough, by the Rev. J. R. Lunn, has been published, illustrated by five lithographs of the most worthy points of detail. A beginning has been made towards copying and publishing specimens of the stained glass in York Minster, resulting in several coloured lithographs representing some of the earliest date, which will appear in the annual volume. This work has been most carefully done by Mr. J. Knowles, glass painter, of York." The chairman said that the balance in favour of the society had been increased during the past year, and there now remained in hand upwards of £100. Mr. G. F. Jones moved the adoption of the report, and the Rev. W. Haworth seconded the motion, which was carried.

ARCHÆOLOGICAL.

SOME ACCOUNT OF ROUGEMONT CASTLE, EXETER.—On the highest part of the hill on which this city is built, and on the north-east extremity, stands the remains of the castle of Rougemont, so called from the redness of the soil. Grafton, in his "Chronicle," says it was the work of Julius Cæsar; afterwards the seat of several Saxon kings, and since of the Dukes of Cornwall. Within the castle walls a chapel was built by the lady Elizabeth de Fortibus, Countess of Devon, who endowed it with lands, called the prebends of Hayes and Catton, for the payment of certain weekly services therein to be performed. This town and castle held out some time against William the Conqueror; but a part of the wall falling down it was surrendered at discretion. William contented himself with only altering the gates of the castle, as a mark of its being subdued; at the same time he either rebuilt or much repaired the whole edifice, and bestowed it on Baldwin de Brioni husband of Albreda, his niece, whose descendants, by the female line enjoyed it, together with the office of Sheriff of Devon, which seems to have been annexed to it, till 14 Henry III., anno 1230, when that prince resuming into his own hands sundry castles and forts in this realm dispossessed Robert de Courtney, in whose family it had been for three descents. In the reign of Henry IV., John Holland, Duke of Exeter, had a fine mansion within the castle, of which no traces are remaining. Anno 1483, the city being visited by King Richard III., he was, during his stay, nobly entertained by the corporation. On seeing this castle, he commended it highly, both for the strength and beauty of its situation; but hearing it was named Rougemont, which, from the similarity of the sound, was mistaken for Richmond, he suddenly grew sad, saying that the end of his days approached; a prophecy having declared he should not long survive the sight of Richmond. In the year 1588, at the Lent assizes held here, an infectious distemper, brought by some Portuguese prisoners of war, confined in the castle, destroyed Sir John Chichester, the judge; eight justices, eleven ont of the twelve empanelled jurors, with divers other persons assembled on this occasion. During the Civil Wars the town was several times besieged and taken by both parties; but there is no account of any further particular defence or capitulation made by this castle. In the year 1655, John Penruddocke and Hugh Groove, both Wiltshire gentlemen, having joined in an unsuccessful attempt in favour of Charles II., were here beheaded, when many of an inferior rank were hanged at Heavitree gallows. The only remains at present are the strong and stately gateway (the original entrance from the city), and which is, perhaps, as venerable a vestige of Saxon fortification as any now extant in this kingdom. It consisted of an inner and outer gate, flanked by strong curtains, supported by buttresses; on the top of the gates are lunettes and machicolations for throwing down offensive things on the besiegers in case of an attack; and in the inner gate there are grooves for letting down a portcullis. The whole of the gateway projected from the wall and flanked the ditch. It was used in 1841 as a black-hole for offending soldiers, and inside was built a guard-house and store-rooms for the East Devon regiment of militia. Any visitors coming to Exeter should not forget to pay a visit to this famous old castle and grounds (which are most admirably laid out with splendid flower beds, &c.), which they can do through the kindness and permission of Mrs. Gard, the present proprietress, who allows any respectable persons to do so by leaving their names. The hours of admission are from ten to four.

THE OLD HOUSES NEAR BIRMINGHAM.—Mr. A. C. Everitt recently read a very interesting paper before the Archæological section of the Birmingham and Midland Institute, on the subject of "The Old Houses in Our Neighbourhood," illustrated with fifty sketches of the most remarkable remains. He divided his subject into three parts, first describing stone houses, then half-timbered houses, and then brick and stone houses. The buildings of oldest formation were of stone, partaking more or less of the castellated character, protected in many instances by a broad moat; these were erected in the period ranging from the 14th to the 16th century. The half-timbered houses were chiefly of the 15th and 17th century work; whilst those of brick and and stone were constructed from the 16th to the 18th century. Under the first head Mr. Everitt described Maxtoke Castle, near Coleshill—rather a fortified manor house than a castle, and in many respects a most perfect relic of the middle of the 14th century; Astley Castle, another embattled mansion, a few miles from Maxstoke; New Hall, a moated house, near Sutton Coldfield, which, previous to the alterations now in progress had the most picturesque outline and appearance of any in our neighbourhood; Baddesley Clinton; and Coughton Court, between Birmingham and Alcester. The list of old stone houses also included a mention of the former rectory at Solihull, in the rectory grounds; and several houses at Sutton Coldfield, traditionally ascribed to the time of Bishop Vesey (16th century). Amongst the remains of ancient timber houses were the following:—The old hall of the Knights Templars at Temple Balsall, or Knowle; Oak House, West Bromwich; Berry Hall, near Solihull; Grimshaw Hall, near Knowle; Whateley Hall, near Hampton-in-Arden; the old house at Barnt Green; Blakeley Hall, Yardley; Pipe Hayes, near Erdington; Solihull Hall; the old Free School at King's Norton; and Packwood, near Baddesley Clinton. The brick and stone houses noticed were Pooley Hill, near Tamworth; Pillaton, near Penkridge; Perry Hall (Perry Barr); Hillfield Hall, Solihull; Grafton, near Bromsgrove; Sheldon Hall, Castle Bromwich Hall, and Aston Hall. In conclusion, Mr. Everitt remarked upon a number of specimens showing the gradual transit from the Elizabethan to what might be called the Georgian mansion, in which, by degrees, the picturesque character of gables, chimneys, and mullioned windows changed, and became more commonplace. He earnestly hoped that proprietors of old places would give their strenuous exertions to aid in preserving rather than restoring those heirlooms of departed generations.

Building Intelligence.

CHURCHES AND CHAPELS.

CHURCH BUILDING IN THE DIOCESE OF MANCHESTER.—In the diocese of Manchester there have been eight churches consecrated within Bp. Frazer's first year, seven of them new edifices—including Emmanuel, Preston; S. Paul's, Low Moor; Christ Church, Blackpool; and S. John the Evangelist, Accrington, and one for reconstruction, S. Bartholomew's, Westhoughton. Four churches were enlarged or restored, six are described as built, but not ready for consecration, SS. James and Mark, Bolton; and S. Stephen, Haslington Grange; eight are rebuilding—three at Bolton, one at Douglas (Eccleston), one at Leigh, and one at Bacup; three are being enlarged or restored—S. Martin's, Witton; and S. Saviour's, Bamber Bridge; and fourteen are in course of building, two of them at Blackburn, and three in the neighbourhood of Bolton. The new churches "proposed" number twenty-six, and the lists include the following places:—Blackburn, S. Luke (Bank Top), Pleckgate, Rishton, Shevington, Carnforth, Oswaldtwistle, Church Kirk, Hapton, Brierfield, and Habergham Eaves.

DUNMOW.—It has been determined to reseat, re-arrange, and warm the parish church of Dunmow. A committee has been formed to carry out the work, to obtain plans, &c.

FRAMWELLGATE MOOR.—S. Cuthbert's church-of-ease, erected at Framwellgate Moor, near the city of Durham, from designs by T. C. Ebdy, F.R.I.B.A., was opened for divine service last week. The foundation-stone was laid by the very Rev. the Dean of Durham in May last. The chapel will accommodate 150 adults. The plan consists of nave, 42ft. 6in. by 21ft.; chancel 21ft. 3in. by 21ft.; organ chamber, and vestry. The pulpit, reading-desk, communion-table, and chancel stalls are executed in Dantzic oak. The style of architecture is early Geometrical English Gothic, with open timber roof. The nave is lighted with candle standards, formerly in the Cathedral, and the chancel with a large corona. In the centre of the frontal of the altar-cloth is a magnificent cross, seventeen inches in diameter, of crimson and gold silk—a facsimile of the jewelled gold cross found in the coffin of S. Cuthbert, now in the library of the Cathedral. The chapel is warmed by Haden's hot air apparatus.

ALL SOULS', LANGHAM-PLACE.—Mr. A. W. Blomfield, in compliance with instructions from the Marylebone Vestry, has prepared a report on the condition of the exterior of All Souls' church, Langham-place. The building, with the exception of the main plinth, which is of Portland, and the plinth of the Corinthian order round the spire, which is of granite, is constructed of Bath stone, and the present lamentable state of decay is, in Mr. Blomfield's opinion, owing to the want of care in selecting the material, and the disregard in some cases of its natural bed. Mr. Blomfield recommends that the tower, spire, and portico be first undertaken, and that they should be thoroughly done by a careful and experienced mason, under the supervision of the Chief Surveyor, without any cement repairs except for pointing. He thinks that the festoons of fruit and flowers might very well be restored to the Ionic capitals, and with very good effect. They could easily be executed in terra cotta and securely fixed in their proper places. The cost of restoring the stonework in the manner proposed would, Mr. Blomfield admits, be considerably larger than in the way recommended by the Chief Surveyor; but the latter plan would be found in the end to be false economy, besides having an unsatisfactory appearance in the first instance.

BUILDINGS.

LONGSIGHT.—The Board of Guardians of the Chorlton Union have resolved to borrow a sum not exceeding £3,000, to enable them to proceed with certain additions to be made to the female lunatic wards at the workhouse.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—T. S. B., J. G., G. H. G., T. C. R., H. W. G. S. S., E. A. D., A. P., E. W. S., J. M., J. G., J. G. W., C. H., S. & Co., O. W. D., J. C., D. M., C. & G., J. N., W. E., G. R. R., B. W., A. B. H., E. W. S., M. P., T. G., G. H., W. W., R. B. M., W. B., T. B., G. H. G.

E. W. BROWN.—Your sketch came too late and is returned. Besides, it is not up to the mark.

E. T. R.—MS. to hand.

TEN YEARS SUBSCRIBER.—We think at Eastwood's Belvedere-road, Lambeth, or the Broomhall Brick and Tile Co., Cox's Wharf, Upper Ground-street

A. S.—The sketch book will not be continued for another vol., or not at present, at all events.

W. L. G.—The drawing came too late; besides, it was hardly suitable.

"H. S" says I am rather astonished to see in our local sheet almanacks the professions "architects and surveyors," "architect and civil engineer," &c., figuring conspicuously amidst hosiers, glovers hatters, boot and shoe makers., &c., &c. I am still more astonished that having paid for their names appearing in such a place they do not take the full advantage of it, and state that plans, &c., are made on the shortest notice and most reasonable terms, and repairs neatly executed, but I presume this is implied."

LIEUT.-COL. SCOTT, R.E.—Proofs returned too late to make all the corrections.

Correspondence.

SATURDAY HALF-HOLIDAY.

(To the Editor of the BUILDING NEWS.)

SIR,—It has been suggested that something should be done to obtain the Saturday half-holiday for such in the architectural profession as at present are denied it. And as it will greatly facilitate the matter to know to what extent the half-holiday is recognised by the profession, will you kindly allow me to ask, through your columns, if one gentleman in each office in London will communicate with me, stating whether or not the Saturday half-holiday is the custom in his office. The result of this I shall be glad to forward you, but of course withholding names.

By inserting this you will confer a great favour on such as, like myself, are kept behind the age.
—I am, &c., A. Y. Z.

76, Church-road, Southgate-road, N.

KITCHEN BOILERS BURSTING.

SIR,—I trust the importance of the subject will excuse my again encroaching on your valuable space. Having pondered the matter since writing my former remarks at page 74 of your columns, perhaps my conclusions may be useful, being the result of practical experience as well as viewing the subject theoretically. I insist upon three things :—

1st. That, as I said, the pipes to and from boiler be laid with an inclination downwards towards boiler in every part of their course (I do not refer to branches).

2nd. That these two pipes, the cold supply and the hot expansion pipe, be both wrapped round with felt in all extent.

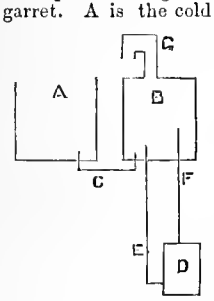
3rd. You may have a hot water hermetically-sealed tank or tanks, branching off the boiler, but these are not to the purpose for keeping the boiler from bursting; what I consider should be put in for safety is a hot-water revolving cistern, with a lid, which can be at least in part lifted off and on if wanted. When said lid is down, the steam which rises off the water gets away through a 3in. pipe, which is carried up to roof. As the hot water cistern I refer to is generally placed in the garret, it is of course near the roof. This hot cistern may be either large or small, according to circumstances, while its use in frosty weather is this—the boiler getting warm, the water in it begins to rise up the expansion pipe, and of course goes into cistern and heats it a little ; but while the water in the one pipe goes up, the other then goes down, and by thus revolving continually, the water in the hot cistern with the two pipes connecting it and the boiler, all get hot, so that there is no danger of bursting of the boiler from frost in such a case so long as a supply of water and fire is kept up.

I append postscript with sketch if judged necessary to give it.

As to the gas idea at page 98, I am afraid it is too complicated, and I cannot see how it can be put in for "only a few shillings;" besides, it is not self-acting, nor continuously acting, as is the hot-water cistern I have above referred to, unless the gas is lighted. Supposing it would act then, it would be useless, while in many cases the gas might be lighted when not required, and possibly omitted when really necessary. Consequently I think that the foregoing plan I have given, though nothing new, will be found to work best, and to be also by far the cheapest.—I am, &c.,

PLUMBER.

P. S. The following is a sketch of a hot-water cistern placed alongside of the cold-water one in a garret. A is the cold cistern, B the hot one (which may be of iron or wood lined with sheet lead), C is the water pipe which supplies B from A, and which enters both cisterns at bottom. The cold cistern A is of course filled in the usual way, which the plumber looks after, as well as overflows, &c. D is the kitchen boiler, E the pipe going down to it, and F the hot or expansion pipe, from which the different branches can be taken off. It will be observed that F rises about 2in. higher than E. G is the 3in. steam pipe open to outside.



ARCHITECTS AND THEIR ASSISTANTS.

SIR,—Could you kindly enlighten us on the following subject, and would you at the same time do us the favour of inserting this in your next issue, in order that some of your numerous correspondents may give us their opinion on the matter.

In a small town in the West of England, where there are *three* or *four* architects' offices, the principals have lately had a meeting to discuss the propriety of allowing their assistants to take out quantities, and supply builders with the same after office hours, when they very soon came to the conclusion, "That it should no longer be done with their permission," and some stated, "That they would not allow any works whatever to be performed by their assistants on their own account." And have given us notice accordingly.

Why this subject was brought up we cannot say, unless our employers are afraid that the small amounts we have received the last few years for similar works has not been properly applied.

If the practice is on any reasonable grounds objectionable, we do not wish to continue it. But as we cannot see the objection, it being an advantage to us and no injury to our employers, we feel it very sharp practice.

Information on this matter will greatly oblige, —Yours, &c., WOULD-BE-INDUSTRIOUS.

THE INSTITUTE AND YOUNG ARCHITECTS.

SIR,—"They must help themselves who would have others help them," is an old proverb and a true one ; it suits the present position of the junior members of the architectural profession exactly ; they are doing and have done all in their power to help themselves, and are surely justified in calling upon their seniors, through their representative society, to, at all events, listen to their suggestions. This, the Institute, through one of its most eminent officers, all but declines to do, and oracularly condemns all who would wish to obtain knowledge by a different method (possibly not better) than that with which their seniors, in their day, were satisfied.

"The Institute will examine, but it will not educate," is the dictum that society propounded some years since. Surely their capital would be better invested in training their successors than in Consols ; but it is not in that light that the "Old Women of Conduit-street" view the matter.

The Institute might become the "Alma Mater" of young architects, which they would not forsake when they grew older, and we should not then have to deplore the fact that the members of the Royal Institute of *British* Architects do not number much more than a tithe of the practitioners.

In your article of Feb. 3rd, on "The Family Coach," you notice the fact of there being so few students at the Institute. Is this to be wondered at? What can they study? What advantages are offered them beyond—

1st. The hearing learned papers, usually Archæological (though now apparently changing for the more practical) on alternate Mondays during the session ; these I am sure you will agree do not in themselves furnish sufficient food for the young architectural mind to feed upon.

2nd. The competitions for the prizes, &c., which truly deserve more notice than they receive.

3rd. The use of the library. One drawback to this very valuable privilege is the fact of its not being a circulating one. Persons, when absolute reading is concerned, usually prefer solitary study, and it is here that the very small library of the Architectural Association tells with advantage, the books continually changing hands.

Of course it cannot be expected that the scarce and very costly works, of which the Institute possesses so many, should be bandied about in this manner, but it would surely be better that the generality of the volumes should become worn out, through the fair usage of many successive hands, than that they should remain intact upon the shelves in all the glory of unsullied binding.

The poor success of the Art Classes may, I think, in a great degree be attributed to the excessive fees in comparison with those of the various schools of art which for elementary teaching answer the purpose equally well. Advanced students have not much inducement to join, as so few can devote two evenings per week to the study of *one* subject, when there are so many others demanding his attention ; true, he need not attend more than one, but still there is an objection to paying double price for any article.

Of the University and King's College classes, many that would prove attractive to architects are held during office hours ; the fees also are by no means low.

With regard to the comparative failure of the Voluntary Examination scheme, may not some portion of the blame be placed to the fact of their being held in the day time during what is often a busy season? In the present lack of architectural work, assistants cannot afford to sacrifice an engagement, even for the chance of obtaining the coveted certificate, nor will principals consent to see their works at a standstill for a fortnight because their assistants have "gone in for the Voluntary."

Trusting you will consider my remarks worthy of a small amount of consideration, I am, &c.

ROBT. E. P.

Feb. 8, 1871.

NEW LAW COURTS.

SIR,—The great disparity in the tenders for the "foundations" of these long contemplated works—the highest being £68,347, and lowest £36,755, showing a difference of £31 592 (which last sum, by the way, is ample for the construction of a moderate sized mansion)—is highly discreditable to one or the other of the competitors, and naturally? evokes the question, Whose tender ought to be relied on Or should either be considered?

The acceptation of the highest tender is not often recorded, therefore of it I'll say nothing, but if I were one of the jurors appointed to decide upon the merits of the tenders submitted, unless it can be made apparent that the lowest has been based upon erroneous "quantities"—(in this case they must be something most egregious) which with reason, to practical men, will account for some thousands of pounds—I would certainly object to it ; indeed, as a rule, I should always pause before I accepted the *lowest* tender, as I do not recognise the policy of doing so.

If several contractors tender for a job I should propose to take the *mean of the aggregate whole* of the tenders, as the nearest approximate real value of the works, provided the mean amount arrived at be not inconsistent or seriously at variance with the architect's estimate of their cost.

It is difficult to conceive in "foundation work," where the quantities of material and the items to be computed are so few in comparison with those required for a perfect and finished structure, how any discrepancies of consequence can arise.

The tenders cannot but reflect very seriously on one or the other of the two contractors, between whom there is such an almost unprecedented difference ; therefore, from one of them, it is not too much, I hope, to expect, as we see the effect, startling as it is, that the cause be shown, by way of solving the mystery.

If more than one surveyor has supplied the quantities, I am not much surprised at the extraordinary result of the competition—*one set* only of bills should be allowed, as I hinted in your issue of Jan. 20 last.—I am, Sir, &c.,

J. M. L., Battersea.

Intercommunication.

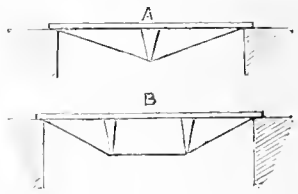
QUESTIONS.

[2119] VAL DE TRAVERS ASPHALTE.—Will you kindly state in BUILDING NEWS where I can obtain particulars as to cost, &c., of the Val de Travers Asphalte?—W. USHER.

[2120] DRAWING BOARDS.—I have a double elephant drawing board, made by Stanley. When I strain a sheet of paper on it I find the next day and every day that the paper comes up all over in waves. On holding it for a short time before the fire it stretches all right again, but soon returns to its slackened state. Will some reader inform me the cause of this and the remedy?—ANNOYED.

[2121] OLD S. PANCRAS CHURCH.—Will some correspondent inform me what is the date of this Norman building, which stands at the back of S. Pancras Station, and, I think, opposite the workhouse? Should like to know whether it is good old architecture or modern.—YOUNG ARCHITECT.

[2122] STRAIN ON TENSION ROD.—Will some kind reader give me the formula for calculating the strain on tension rod and horizontal thrust of beam of the following



form of trussed beam, and example of each worked out?—A SUBSCRIBER.

[2123] REMOVING COLOURS.—Would any reader of "Intercommunication" kindly inform me what will take out any of the following colours :—Prussian blue, yellow ochre, brown, and Paine's grey.—F. W.

[2124] CRUSHING WEIGHT OF STONES.—Can any of your numerous readers give me any information as to the crushing weight of the following stones, viz., Ancaster, Darley Dale, and White Mansfield?—X. Y. Z.

REPLY.

[2104] TEMPERATURE OF DAIRIES.—I quite agree with "W. W." that a cheese room requires an equal temperature of 65 deg., but a milk room which it is proposed to build on the ground floor should be at least 15 deg. colder, and to preserve this low temperature during the summer months it would be found advisable, if practicable, to sink the floor a few feet below the adjoining ground, the walls being built hollow for the prevention of damp. The use of hot water pipes is quite unnecessary, for I am convinced from my own experience that if the dairy be built in the above manner, with careful attention to the admittance of fresh air, a tolerably equal temperature of about 50 deg may be maintained. A verandah round the dairy would be very convenient in shading from the sun in summer and adding to the warmth in winter, and would also form a favourable place for drying and airing the utensils in rainy weather.—FARMER.

WATER SUPPLY AND SANITARY MATTERS.

THE GOVERNMENT AND THE DRAINAGE OF TOWNS.—At a meeting of the Windsor Local Board of Health on the 25th ult., the following letter was read from the Local Government Act Office, in answer to an inquiry made by the Board as to whether the Government contemplated legislating for the whole kingdom in regard to the drainage of towns:—"Local Government Act Office, 8, Richmond-terrace, Whitehall. Jan. 3, 1871. Sir,—I am directed by Mr. Secretary Bruce to acknowledge the receipt of your letter of the 29th ult., with reference to the report that the Government intend legislating for the whole kingdom in respect of the drainage of towns. In reply I have to inform you that I am unable to give you any official information on the subject of your letter. It is generally expected that some legislation affecting the whole kingdom in relation to local improvement, of which town sewerage must form an important element, will be the result of the report of the Sanitary Commission, but the report has not been sent in, or if sent in, has not yet reached this department.—I am, Sir, your obedient servant, J. MONTAGUE, Chief Clerk.

LAND AND BUILDING SOCIETIES.

COLCHESTER PERMANENT BENEFIT BUILDING SOCIETY.—The annual meeting of this society was held on Monday last. The annual report of the Directors was read and adopted. Messrs. Harvey, E. S. Sanders (vice-chairman), J. Bedwell, and T. Moy were re-elected. The report stated that during the past year 11¾ borrowers' shares were discharged by lapse of time, and 46¾ were paid off by the mortgagees at periods short of those for which the loans were granted. The advances made during the past year amount to £7,150, being £3,175 more than in the previous year. The total advances for the 14 years were £71,315, averaging more than £5,000 a year.

THE NATIONAL FREEHOLD LAND SOCIETY.—Last week the twenty-first annual meeting of this society was held at the Terminus Hotel, Cannon-street, Mr. C. Gilpin, M.P., in the chair. The chairman, in moving the adoption of the report, said he had really nothing to add either to the statements in that document or to the very full, clear, and accurate balance sheet which had been laid before them He would not go out of his way to make a speech when they had simply to transact business, and when there was nothing else but business to talk about. Taking, then, the report, he found that the balance sheet for the past year showed a decrease in the deposits received of £82,327 as compared with the previous year, while on the other hand the withdrawals were less by £31,430. The capital of members was £11,210, the amount at the end of the year being £1,088,266, as compared with £1,099,476 at the end of the preceding year. The amount advanced on freehold and leasehold securities had been £20,094 more than in the previous year, while the repayments were £12,667 less, owing to the increased facilities given to borrowers by extending the time for repayments, by allowing advances to remain at interest only after the balance is reduced, and by lending at a fixed rate of interest for three years certain. All these changes had been made in the interest of borrowers, and he thought the result had proved that they were beneficial also to investors. He was happy to say that a further sum of £55,917 had been added to "convertible securities," making the total amount of these securities £21,918. The gross profit for the year was £58,476, and after deducting current expenses, interest paid on completed shares, and the profit added to uncompleted shares, there remained a balance of £19,738. Of this amount the board had placed a further sum of £5,000 to the credit of the reserve fund, which now stood at £20,000, and the directors recommended that a bonus of 1 per cent. be paid to the members, as on the last occasion.

THE UNITED LAND COMPANY (LIMITED).—The annual meeting of the shareholders took place on Monday at the Norfolk-street office. The report stated that the sale of land had amounted to £39,176 1s. in various counties, that the whole of the preliminary expenses were paid off, that a contingency fund of £1,000 had been created, and a considerable balance taken forward to next year's account. The dividend declared was 5 per cent. for the year, and a bonus of 3 per cent., making a total dividend for the year ending 31st December, 1870, of 8 per cent.

LEGAL INTELLIGENCE.

COURT OF BANKRUPTCY, FEB. 8.—RE EDWARD CORDERY.—This was an order of discharge sitting under the heavy failure of Edward Cordery, of Cunningham-road, Hammersmith, builder, who petitioned the Court on the 10th November, 1868, by Mr. J. R. Chidley, solicitor, Old Jewry Chambers. Mr. W. Upwan, of Copthall Court, attended as solicitor for the assignees. The voluminous accounts, compiled by Mr. J. J. Kent, of Basinghall-street, upon which the bankrupt passed his examination on the 12th January last, and which has been appealed against before the Lords Justices, disclose total debts, £28,377 11s. 10d, and deficiency £23,050; his expenditure had been £630 for the last two years of his trading Mr. Upwan said the appeal had not yet been decided by the Lords Justices. Mr. Registrar Hazlitt: Then in that case I cannot proceed with the order of discharge. The sitting must be adjourned for a month, with liberty to apply for an earlier day should the appeal be sooner decided.

COURT OF BANKRUPTCY.—IN RE ALBERT JOHN TATHAM.—(Before Mr. Registrar Spring Rice acting as Chief Judge.) The debtor in this case, who is described as of No. 14, South Wharf, Paddington, Cement Merchant, filed a petition in this court on the 27th January under the arrangement clauses of the Bankruptcy Act, 1869. His liabilities are estimated at over £10,000 and the assets are believed to be of considerable value. His affairs have created considerable interest amongst persons engaged in the lime, cement, brick, tile, and building trades, some of the principal firms in which will be heavy losers.—On the application of Messrs. Lewis Munns, Munn & Longden an order was on Saturday made appointing Mr. Horatio Edward Norfolk, of 11, Coleman-street, public accountant, receiver and manager of the debtor's property and business.

IMPORTANT TO SURVEYORS OF LOCAL BOARDS.—In the Court of Queen's Bench on the 27th ult., before Mr. Justice Blackburn, Mr. Justice Mellor, and Mr. Justice Lush, a case was heard which raised a question of some interest to surveyors and local Boards. It was an action against the Corporation of Canterbury—the local Board, and as such Board, surveyors of highways—for an injury caused to a Mrs. Forman by the negligence of their servants. It appeared that their men had placed upon a road going to Canterbury 20ft. wide, a heap of stones extending 7ft. across the road, and had left it there without a light. The plaintiff was driving his wife, on a dark night, along the road, and the horse not seeing the obstruction ran the chaise up against it and upset it. The result was that the wife was very seriously and permanently injured, having lost the use of her arm for life, and being so disabled as to necessitate the employment of a housekeeper. The defendants' counsel at the trial before Lord Chief Justice Bovill at Maidstone, last summer, admitted that the Board caused the obstruction, but insisted that there was no liability for it, as they had a right to put stones or other materials on the road for the purpose of repairs. The Lord Chief Justice, however, ruled that they were bound to use reasonable care in so doing, in order to avoid danger of accidents, and it would be for the jury to say whether they had been guilty of negligence, or whether, as was suggested, the accident happened by reason of the darkness of the night. The jury found for the plaintiff, damages £1,200, and the Lord Chief Justice at the same time declared that he was satisfied with the verdict. The verdict was now impugned on the ground that the Corporation were only liable as local board and as surveyors of highways; and that, in that capacity, they were not liable to an action. Mr. Hawkins, Q.C., and Mr. Archibald were for the plaintiff; Mr. Dennan, Q.C., and Mr. G. Francis were for the Corporation. The court were clearly of opinion that the action was maintainable against the Corporation, as it was admitted that their servants had caused the obstruction.—Judgment for the plaintiff.

Our Office Table.

MR. PUGIN'S TRIAL FOR ASSAULT AND LIBEL.—At Ramsgate Townhall, on Saturday last, Mr. Edward Welby Pugin was summoned for assaulting Thomas Jones Burton; and a cross summons was also called between the same parties, but neither of them appeared, and the case was dismissed. At the same time Mr. Edward Welby Pugin and Mrs. Jane Welby Pugin, his mother-in-law, and Bernard Welhan (late secretary to Mr. Pugin), were summoned for maliciously publishing defamatory libels against Mr. John Barnett Hodgson, postmaster at Ramsgate, and Miss Fanny Elizabeth Hale, his niece. The solicitor for the prosecution stated that counsel for the defendants having applied to Mr. Straight, M.P., who is specially retained for the prosecution, to have the case adjourned till that day week, Mr. Straight had consented. The solicitor therefore asked for an adjournment till the following Saturday (to-morrow). The Bench granted the application. The case has excited a great deal of interest on account of the position of the parties, and also from the fact that Mr. Welby Pugin is held to bail till the ensuing spring assizes for Kent upon a charge of libel against Mr. Hodgson.

NEW WORKS AT SOUTH KENSINGTON.—On Saturday afternoon last about forty of the members of the Architectural Association were conducted by Mr. Gilbert R. Redgrave over the buildings for the new Science Schools and the new South Court of the Museum. The former is a very lofty and imposing block, facing the Exhibition-road, and executed in red brick, with terra-cotta ornamentation. In this building will be included four or five large lecture-rooms or halls, and numerous rooms for classes, &c. The terra-cotta work has been executed by Mr. Blanchard, of the Blackfriars-road, the weight on the columns of that material being borne internally, however, by strong iron stanchions. The floors are on Fox & Barrett's principle. Facing this block of buildings, and connected with it either by an iron bridge across, or a subway beneath, the Exhibition-road, will be the new Indian and Natural History Museums, which will be erected on a part of the site of the Exhibition of 1862. The new South Court is much loftier than any of the other courts yet erected, and is intended for objects of great size. This court will be, like the most recent court completed, a double one—*i.e.*, it will be in two spans, with upper and lower colonnades running along the entire length of the building, and dividing it into two halves, each spanned with a semicircular iron and glass roof.

ALBERT HALL.—Considerable progress has been made during the last few days towards the completion of the internal arrangements of the hall. The ugly but necessary scaffolding has all been removed, and the whole of the glass roof has been uncovered, so that the fair and beautiful proportions of the building are now displayed to the view of the spectator. These proportions will possibly never be seen to greater advantage than now; in a day or so, hangings, curtains and chairs will break the graceful curves. The curtains of the private boxes will be of crimson, and the carpeting of them green. In every other respect the fittings will be according to the tastes of the holders, who will be allowed full license, so long as the general effect is not interfered with. The bright, massive pipes of the organ are being rapidly reared in their places, and in all the departments the utmost activity is being displayed under the superintendence of Lieutenant-Colonel Scott and Mr. Wentworth Cole, to perfect the arrangements by the day of the opening ceremonial by the Queen.

INSTITUTION OF SURVEYORS.—At the ordinary general meeting, held on Monday, January 30th, the following names were read and passed for ballot, viz.:—As Members,—Rowland George Fisher, 17, Great George-street, Westminster; William Frederick Hart, 16A, King's-road, Bedford Row; William Knowles, King-street, Gloucester. As Associate,—Joseph Quick, jun., Sumner-street, Southwark. The following Donation to the Library Fund was announced,—J. C. Clayden, £2 2s. The following Candidates were balloted for and declared duly elected:—As Honorary Members—The Hon. Charles Alexander Gore, Office of Woods, Forests, &c., Whitehall-place; the Hon. James Kenneth Howard, Office of Woods, Forests, &c., Whitehall-place. As Member—Alexander Milne Dunlop, 1, Westminster Chambers, Victoria-street. The next Meeting will be held on Monday Evening, February 13th, when the discussion on the Paper by Mr. W. Matthews, jun., entitled, "The Valuation of Annuities and Reversions Dependent upon Terms of Certain Duration," will be resumed. The Chair to be taken at eight o'clock.

THE MAINTENANCE OF HIGHWAYS.—At a meeting of the Somerset Chamber of Agriculture on Friday last, the Council proceeded to consider the injustice of the exemption from highway-rate of income arising from personal property, and after a general discussion the following resolution was adopted:—"That in the opinion of this Council, public highways of every description tend to cheapen the price of commodities to all classes of consumers; and, therefore, that the maintenance of the highways should be an imperial charge to be borne by the public."

Chips.

A site for a new church has been purchased at Rishton, Lancashire.

The case of Mr. Hemans, civil engineer, against the Waterford and Central Ireland Railway Company, was before the Irish Court of Queen's Bench last week. The claim was for £5,600 for professional services, and at the trial the jury gave him a verdict for £740, but he moved the Court to increase the amount, and on Wednesday the judges fixed the damages at £1,680.

On Sunday last the gallery in the United Methodist Chapel, at Troon, Camborne, gave way soon after the commencement of the sermon. The gallery was moderately full, but no one was seriously injured.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—*Institution of Surveyors.*—Discussion on Mr. W. Matthews's paper "On the Valuation of Annuities and Reversions Dependent upon Terms of Certain Duration." 8 p.m.

Architectural Association.—"On Limes and Cements." Lecture II. By Lieutenant-Colonel Scott, R.E. 7.30 p.m.

TUESDAY.—*Institution of Civil Engineers.*—8 p.m.

WEDNESDAY.—*Society of Arts.*—8 p.m.

FRIDAY. *Civil and Mechanical Engineers' Society.*—"Notes on Old London: Architectural and Engineering." By Mr. C. H. Rew. 7.30 p.m.

Timber Trade Review.

PRICES 7th February:—Timber, per load of 50 cubic feet.—Riga, 65*s* to 67*s*; Dantzig and Memel, crown, 80*s* to 90*s*; do. best middling, 70*s* to 80*s*; do. good middling and seconds, 62*s* to 67*s*; do. common middling, 52*s* to 57*s*; do. undersized, 52*s* to 60*s*; do. small, short, and irregular, 45*s* to 55*s*; Stettin, 53*s* to 60*s*; Swedish, 52*s* to 55*s*; do. small, 45*s* to 50*s*; Norway and Swedish balks, 32*s* to 38*s*; Quebec yellow pine (large), 85*s* to 105*s*; building sizes, 65*s* to 75*s*; St. John's and board pine, 75*s* to 90*s*; pitch pine, 60*s* to 75*s*; Quebec oak, 120*s* to 125*s*; elm, 85*s* to 95*s*; birch (large average), 75*s* to 100*s*.

Planks, deals, &c., per Petg. std.—Archangel yellow, 12*l* 10*s* to 13*l* 10*s*; do. 2nd, 9*l* to 9*l* 10*s*; Petersburg yellow, 12*l* 10*s* to 13*l* 5*s*; Wyburg yellow, 9*l* 5*s* to 9*l* 10*s*: Finland and handsawn Swedish, 7*l* to 9*l*; Petersburg and Riga white, 8*l* 10*s* to 9*l* 5*s*; Gefle and best Swedish deals, 10*l* 10*s* to 12*l*; Swedish battens, 9*l* 10*s* to 10*l* 10*s*; Quebec 1st floated, 16*l* to 17*l*; do. 2nd, 12*l* to 12*l* 10*s*; do. 3rd, 8*l* to 9*l*; do. 1st bright, 18*l* to 19*l* 10*s*; do 2nd, 12*l* 15 to 13*l* 10*s*; do. 3rd, 8*l* 15*s* to 9*l*; Canadian spruce, 1st quality, 8*l* 15*s* to 11*l*; do. 2nd, 8*l* 5*s* to 8*l* 15*s*; do. 3rd, 7*l* 15*s* to 8*l*; New Brunswick, 1st quality, 8*l* 5*s* to 8*l* 15*s*; do. 2nd, 8*l* to 8*l* 5*s*; do. 3rd, 7*l* 5*s* to 7*l* 10*s*; do. unsorted, 7*l* 15*s* to 8*l* 10*s*; Nova Scotia and Prince Edward's Island, 7*l* to 7*l* 10*s*; United States pitch pine planks, 12*l* to 12*l* 10*s*.

Flooring boards, per customary square.—1st yellow, 7*s* 6*d* to 10*s* 6*d*; white, 7*s* to 9*s* 6*d*; 2nd qualities, 6*s* to 7*s*; matched boards, 5*s* to 7*s* 6*d*.

Lathwood, per cubic fathom.—Petersburg, 5*l* to 5*l* 10*s*; Riga, Dantzig, Memel, and Swedish, 3*l* to 5*l*.

Firewood, per cubic fathom.—Swedish red deal ends, 3*l* 15*s* to 4*l* 5*s*; Norway red and white boards, 3*l* to 3*l* 10*s*; round and slabs, 2*l* 5*s* to 2*l* 15*s*.

Oak staves, per mile of pipe:—Memel crown, 170*l* to 180*l*; do. brack, 130*l* to 135*l*; Dantzig, Stettin, and Hambro' full-sized crown, 120*l* to 130*l*; Canadian standard pipe, 75*l* to 77*l* 10*s*; do. puncheon, per 1,200 pieces, 22*l* to 24*l*; Bosnia single-barrel, per 1,200 pieces, 25*l* to 26*l*; United States pipe, 40*l* to 50*l*; hogshead, heavy and extra, 35*l* to 45*l*; slight 30*l* to 32*l*.

Wainscot, per log 18 cubic feet.—Riga crown (English and Dutch), 4*l* to 5*l*; do. brack, 2*l* 10*s* to 3*l* 5*s*; Memel and Dantzig crown, 3*l* 15*s* to 4*l*; do. brack, 2*l* to 2*l* 7*s*.

TENDERS.

BLACKFRIARS.—For fittings at 38, New Bridge-street, Blackfriars, for Messrs. Spiers & Pond. Quantities supplied by Messrs. Pain & Clark :—

	Spanish mahogany.	Deduction if Honduras mahogany.
Thompson	£685	£50
Cook & Green	575	55
Lascelles	556	56
Manley & Rogers	555	31
Drew	535	20
Bracher & Son (accepted)	499	50

BEDFORDSHIRE.—For alterations and addition to Blunham house, Bedfordshire, the residence of Sir S. G. Payne, Bart. Mr. John Usher, architect. Quantities supplied :—

Fletcher	£3140 0
Moore	2769 0
Hutchinson	2596 0
Twelvetrees	2558 0
Cunvin	2555 0
Freshwater	2550 0
Carter	2435 0
Wildman & Edey	2420 0
Young	2327 0
Hull	2176 10
Spencer	2139 0
Vickers	2119 10
Foster (accepted)	1989 0

CATERHAM.—For house in Whyteleaf-road, Caterham, Surrey, for Mr. G. H. Drew. Mr. R. Martin, architect. Quantities supplied by Mr. F. Sparrow :—

Turner & Sons	£1069
Jarrett	1063
Langmead & Way	1050
Ward	1044
Smethurst	1029

CHELSEA.—For alterations and additions to St. George's Hanover-square, Union, Fulham-road, Chelsea :—

Turrell (Sloane-street)	£2594
Heushaw	2593
Newman & Mann	2525
Nutt & Co.	2493

CONTRACTS OPEN FOR BUILDING ESTIMATES.

WHITCHURCH, Feb. 20.—For the erection of town-hall and markets in Whitchurch, Salop. Local Board Officer Whitchurch, Salop.

WHITCHURCH (Whitchurch Local Board), Feb. 20.—For the erection of town-hall and markets in Whitchurch, Salop. S. M. Lockwood, architect, 85, Foregate-street, Chester.

WAR OFFICE, Feb. 25.—For works and repairs, and supply of building materials to War Department. Buildings and property at Ashton-under-Lyne, Birmingham, Bradford, Burnley, Bury, Carlisle, Chester, Coventry, Fleetwood, Hartlepool, Isle of Man, Leeds, Liverpool, Manchester, Maryport, Newcastle-on-Tyne, Northampton, Paull-on-the Humber, Preston, Scarborough, Seaham, Sheffield, Stallingborough, Sunderland, Tynemouth, Weedon, Whitehaven, and York, including the surrounding neighbourhoods, from the 1st April, 1871, till 31st March, 1874.

WAR OFFICE, Feb. 14.—For the supply of materials, and sor the performance of such bricklayers', masons', paviors', carriers', carpenters', slaters', smiths', gas-fitters', plasterers', plumbers', painters', glaziers', and paper-hangers' works and repairs (the estimate for any one work or repair not exceeding £300) as may be required by the Royal Engineer Department at the following stations in the Dover district, viz. :—Dover: fortifications and barracks at Dover, and from Dover to No. 1 Tower westward; and from Dover to (but exclusive of) Walmer Castle eastward. Ramsgate; from Walmer Castle, including No. 2 Battery, Sandown, to Ramsgate and Margate inclusive: Canterbury: barracks. Shorncliffe Camp: including the Royal Artillery Barracks, the temporary barracks, Sandgate Castle, Folkestone and Shorncliffe Batteries, and towers from No. 1 to No. 9 inclusive. Hythe: including Hythe Barracks, coast defences, from 10 to No. 24 Tower inclusive, and Royal Military Canal from Seabrook to Warehorn. Rye: including the coast defences from No. 26 Tower westward to Fairlight, and the Royal Military Canal from Warehorn to Cliff End. T. B. Collinson, Colonel, Commanding Royal Engineers, Royal Engineer Office, Dover.

BOLTON.—Contract C.—March 3.—The Corporation of Bolton are prepared to receive tenders for the joiners' work, plastering, painting, glazing, and plumbers' fittings required for the completion of the new town-hall. The drawings and specifications may be seen, and bills of quantities obtained, on application at the offices of Mr. William Hill, architect, Park-square, Leeds; or at the offices of Mr. George Woodhouse, architect, St. George's-road, Bolton, between the hours of 10 a.m. and 5 p.m., from the 16th day of January next to the 3rd day of February next. Sealed tenders are to be sent in not later than 12 o'clock at noon of Friday, the 3rd day of March next, addressed to the undersigned at the Corporation Offices, Acres Field, Bolton, and endorsed "Tenders for the Town-hall, Contract C." R. C. Hunnell, Town Clerk.

BAKEWELL (Derbyshire), Feb. 16.—For the new schools A. Salvin, architect, 19, Cranley-place, Onslow-square, South Kensington.

BRISTOL LOCAL BOARD OF HEALTH, Feb. 23.—For contructing and completely finishing certain intended brick sewers, valve chambers, and other works in "The Avon Intercepting Sewer District." Length of sewers about 7563 yards, varying in size from 3ft. high by 2ft. 6in. wide to 7ft. 6in. in diameter. John G. Heaven, Clerk, Local Board of Health Office, 13, Prince-street.

BISHOP'S STORTFORD.—Contract No. 2.—Feb. 17.—For sewage, screening and storage tanks, engine and boiler house, and engine-man's cottage, with the necessary connecting pipes and valves, and an approach-road. Contract No. 3.—For duplicate boilers, engines, and pumps for lifting the sewage. William Gee, clerk, Bishop's Stortford.

TORQUAY.—Torquay Hotel Company (Limited), Torquay, Devon.—Feb. 29.—For the erection of additional buildings, &c. Mr. J. Allsop, secretary.

PORTSMOUTH, Feb. 20.—For the erection of a church at Portsdown, five miles north of Portsmouth. John Colson, architect, St. Swithin's-street, Winchester.

CREWE LOCAL BOARD, Feb. 15.—For a non-condensing horizontal pumping engine and boilers; also a condensing beam engine and boilers, for their sewage works at Crewe. Frederick Cook, Clerk to the Board, Temple-chambers, Crewe.

BIRMINGHAM, Feb. 25.—War Department triennial contract for builders' work. Colonel Commanding, Royal Engineer Office, Manchester.

BRADFORD, Feb. 25.—War Department triennial contract for builders' work. Colonel Commanding, Royal Engineer Office, Manchester.

SUFFOLK, Feb. 25.—For the reseating and other work to the parish church of Hadleigh, Suffolk. w. Grimwade, churchwarden, Bank, Hadleigh.

BERWICK-ON-TWEED, Feb. 25.—(1st) Building two tanks, engine and boiler-house. (2nd) Furnishing 30-horse power engine, boiler, pump, &c., and fixing. (3rd) Furnishing 2,700 yards of 9in. cast-iron pipe. (4th) Laying and jointing the same. J. C. Weddell, Clerk to Local Board.

PORTLAND, Feb. 16.—Nine hundred tons of dressed granite for the fort on breakwater. Lieut.-Colonel, Belfield, Commanding Royal Engineers, Weymouth.

ACTON LOCAL BOARD, Feb. 14.—For making up Mill-hill-road. Edward Monson, C.E., surveyor to the said board, Acton.

ACTON LOCAL BOARD (Main Drainage), Feb. 15.—Contract No. 9.—For laying a pipe sewer in Uxbridge-road. Edward Monson, C.E., surveyor to the said board, Acton.

BANKRUPTS.

(TO SURRENDER IN LONDON).

Henry Wiber Webster, King's-road, Bedford-row, builder, Feb. 16, at 12.

(TO SURRENDER IN THE COUNTRY).

Thomas Cook, Greenwich, engineer, Feb. 20, at Greenwich.—Henry Joseph Ingram, Cheltenham, surveyor, Feb. 20, at Cheltenham—John Potter, Dudley, engineer, Feb. 20, at Dudley.

PUBLIC EXAMINATIONS.

Feb. 15, A. Combes, Tyndale-place, Upper-street, Islington, builder—Feb. 20, J. M. Edwards, Thornton-heath, builder—Feb. 27, J. Hughes, Liverpool, builder.

DIVIDEND MEETINGS.

Feb. 21, J. & W. Roose, Ashbourne, Derbyshire, and Stoke, Staffordshire, plumbers—Feb. 15, A. Nuttall, Accrington, stonemason—Feb. 16, J. Oldham, Barrow-in-Furness, builder—Feb. 17, T. & W. English, Peterborough, painters—Feb. 25, G. Godbolt, Gorleston, builder.

DECLARATIONS OF DIVIDEND.

T. Love, Blackpool, builder, div. 1½d.—C. H. Whalley, North Elmham, Norfolk, brickmaker, div. 8d.

PARTNERSHIPS DISSOLVED.

Ashworth & Brierley, Manchester, art metal workers—Hodgson & Co. Castleford, brick and tile manufacturers.—J. & E. Bourne, Shawbury, Mukleton, and Old Woods, Salop, brick and tile manufacturers—J. & D. Petch, Scarborough, architects—J. C. & T. Waller, Dartford, builders—Newman & Thomas, Cheriton, brick, tile, and pipe manufacturers—Swainson & Dufton, Hunslet, plumbers.—Best & Smith, Manchester, painters—Aspinal & M'Grath, Manchester, painters—W. & J. Cardwell, Dewsbury, engineers—Everatt & Rudston, Hessle, joiners—Parker & Sons, Aston, builders.

THE BUILDING NEWS.

LONDON, FRIDAY, FEBRUARY 17, 1871.

TWO SORTS OF ORIGINALITY.

MOST people are agreed that if ever a living and characteristic style of architecture should prevail again, it will differ, at least in some points, from all that have gone before. It will not be exactly the style that prevailed in mediæval England, and still less that which prevailed in ancient Italy or Greece. Our circumstances and wants and feelings are not quite the same as those of the men who developed any previous variety of art. What suited them perfectly does not fit us at all equally well. If we adopt any of their systems, it is entirely for want of a system of our own ; and at every turn we are being reminded of this want. We have no modern English style in the sense in which we have a modern English language. Our architects are situated just as our writers would be if they had to describe manufacturing processes in Ciceronian Latin, or scientific discoveries in the dialect of Chaucer. There are no equivalents for half their ideas : they must either coin new words or resort to endless circumlocutions. To change this state of things, to develope an architectural language adequate to our needs, is a vital necessity for us. The question is how it can best be done. It is worth looking about to see the different ways in which people are trying to do it. A casual observer, indeed, might say that very few people are trying to do it at all, and it is probably true that few are consciously attempting it. But the attempts are not less real because those who make them do not always see fully what they are doing. And in trying to classify the movements which tend towards a modification of style, it would not, perhaps, be a bad division to arrange them as conscious and unconscious ones. On one side are the efforts of one or another designer who sets to work deliberately to be original, who tries to reject the old altogether, and to begin upon a new foundation. On the other side are those of men who, if they strike out a path of their own, do it because they must : who find, perhaps with astonishment, perhaps with regret, that there are more things in heaven and earth than were dreamed of by the builders of the 13th century : who keep to the old as the basis of their work, and where they are obliged to add to it, do so with caution, and, one might say, with reverence.

From which of these two systems have we most to hope? Which finds most promise of issuing at last in a genuine and living modern style? In answering these questions we think that analogy, experience, and probability all point the same way. To begin with the first :—What should we think of a man who set up by himself to invent a new language? Yet this is as much within the compass of a single individual's powers as the creation of a new style. It is just as likely to be accomplished, and just as likely to impose itself on the world when done. But though a project for a new language seems to be beyond the wildest dreams of anybody outside Bedlam, we have heard of projects for new styles and seen samples of them submitted in bricks and mortar for the approval of the public. And though these have not been numerous, there are an abundance of specimens, to be noticed any day, in which the same ambition largely manifests itself. Some of our readers may remember the discussion in these pages of that curious object, the late Strand Music Hall. After all, it was not much worse than many another design of the "all original" type. It only happened to be picked out, in English fashion, as the scapegoat on which all the sins of its class were visited ; and even if it did not get more condemnation than it deserved, certainly some equally flagrant offenders got much less. It is difficult to go far in the streets of any large town without coming on examples little less objectionable. Their architects have produced a variation, indeed, from received types, but anything rather than what Mr. Darwin would call an advantageous variation. They have brought together, perhaps, some queer shape of window head, odder and uglier than any one ever ventured to put up : some absurder type of sham-cornice, and some more astonishing combination of notches and chamfers. There is neither beauty nor use in these novelties. They cannot live ; they cannot be permanent, or contribute anything to a real modern style, because they have no merit except that of being novelties. No one, it is true, can say that he has seen them before ; but no one, it is equally certain, will say that he wishes to see them again. There is no germinating idea in them ; they have nothing to develope; they die out with themselves. A whole infinity of such attempts as these would never produce a new type of architecture.

The truth is, neither new styles nor new languages are produced by men setting to work deliberately to make them. They all have their root in the past. Each of them holds the inventions, not of one individual, however gifted, but of multitudes of men for many generations. Their details, if we could trace their history, did not originate in caprice. It was not by mere chance that the smallest feature in them became what it is. Every constituent has been weighed, and tested, and criticised, and its survival is a proof that it once commended itself to universal judgment as the fittest thing for its situation. Circumstances may have changed, and it may be by no means the fittest now ; and in that case the problem is to replace it by something fitter, which harmonizes equally well with the rest of the system. If replacing it with a novelty were enough, we might soon have a nineteenth century style in working order. Anybody can produce new forms without much trouble : it is not so easy to make them agree either with each other or with what is old. And yet this is what we must do, if architecture is to advance. We have new materials, and new kinds of construction, and new types of buildings to deal with : we have an old style, which in the main is admirable as far as it goes. We shall be wise to stick to it wherever we can. There are plenty of alterations forced on us, without proposing needless ones in pure gaiety of heart. How to succeed in those that are inevitable is quite enough of a puzzle to employ us all. There is, however, one encouragement in trying to solve it. As long as we keep our old style in view we have a model to imitate,—a nucleus round which our ideas may crystallize. Unlike the "all original" architect, we are not absolutely trying to create a new world out of nothing. And unlike him, each of us is not obliged to attempt the whole work by himself. He *must* do so —for as no one else is familiar with his fancies, no one can contribute anything that will agree with them. But with a distinct and homogeneous style for our basis, each of us may labour in his separate department, and be sure that if his work harmonizes with the original, it will also harmonize with that of others who take the same style for their model. So much for the theory. In examining the architectural productions of the day, the facts, we believe, will be found in accordance with it. The buildings that bear looking at oftenest are not always those that seem at the first glance to have most freshness about them. They are those whose originality does not obtrude itself on the view,—whose cleverness does not lie on the surface. They are those in which difficulties are so thoroughly conquered that one forgets for a time that there ever were any difficulties to conquer : in which it is not so much the novelty of the work as its beauty that makes itself felt : and in which the new is so perfectly harmonized with the old, that one only discovers by thinking about it that there are any new features in the design at all.

THE BRITISH MUSEUM.

THE British Museum is, or should be, one of the best schools in London. As a public institution, recreatory and instructive, it possesses indeed numerous and special merits, and of its worst abuses, some are about immediately to be removed. It is to be wished, however, that when holiday occasions, such as Christmas or Easter, attract tens of thousands to the great building in Bloomsbury, means could be provided of sending them away more enlightened, or rather, less confused, on the subject of what they have seen. This does not imply that a staff of Polytechnic lecturers should be kept to marshal the people wand in hand through the galleries, for this would be an intolerable nuisance ; or that every man, woman, and child staring about the collections should feel as if listening to Sir Roderick Murchison or Professor Faraday ; but there might be more life in the exhibition ; they should tell their own story more plainly and better. However, the assemblage is a vast and unrivalled one ; and few among the multitudes which pass the doors imagine what treasures they have missed seeing. They have bewildered themselves by glimpses of stuffed birds, beasts, and fishes ; yet what, for them, the Townley sculptures, or the Phigalean and the Elgin marbles? We leave books out of the question ; we even omit bones, elephant skeletons with false teeth, copavaries with artificial necks, birds of Paradise painted in France ; but turn to the general whole, and invite the reader to follow us. Now, the entrance is decidedly bad ; it presents a handsome appearance, but excludes the light, being too heavily columniated and roofed. This opens into a quadrangle, described by Mr. Granville as "the finest mason's yard in Europe." The ceiling seems always to be falling in ; it requires some energy to find the windows ; and we may choose between a series of cellars illumined, like kitchen-areas, through excavations in the earth, and a range of rooms above, illumined, like attics, through sky-lights. The "stone-shops," as the sculpture chambers are termed, are still worse. Scarcely an attempt at arrangement exists : priests and princes are in the vaults, and bulls on the first floor. Well, this description, which would apply to the old ramshackle structure originally known as the British Museum, applies exactly also to the present. But, after a preliminary protest, we do not care to dwell upon the imperfections of a national establishment which, after all, contains an immense amount of wealth. A great deal has been done. The Belzoni and the Layard antiquities are better placed ; the Blacas gems, though unaccountably locked-up, have a chamber to themselves ; the Granville jewels, at last, have been lifted from the floor upon which they had been trodden for years ; but where is the Granville bust which used to look down so sadly upon all this confusion? But a very large part of the public, especially the Graces, Muses, and Minervas of modern society, care for none of these things. They are the spoilt children of sweet Σοφια, always contented. And in a great degree they are right. They come to see, and to feel amused, or, if a more dignified term be essential, interested. It is nothing to them that the collections are a grand aggregate of objects suitable to many sympathies ; not always identical, yet closely allied; various, but not dissimilar :—

Facies non omnibus una
Nec diversa tamen ; qualem decet esse sororum.

The people who, understanding these facts, roam among the galleries, cannot fail to obtain ideas of beauty and grace. Yet from the Museum they must go to a book. They see the superb Parthenon frieze, they catch its splendour at once ; but they have afterwards

to look for its meaning and history, as the noblest specimen of lithography extant. Otherwise the world opened to their vision here is, and will remain, perfectly unintelligible, a region of hieroglyphics and mysteries; but who can presume to measure the feelings, the intelligence, the tastes, which, in these academies of old times, might not be awakened and developed in the minds of the humblest, had they an easy method of understanding, even to the most moderate extent, the opulence of illustrations placed before them? It is not that the outside populace, on holiday purposes intent, can be expected to study the colossal monuments of antique epochs, of Egypt, Lycia, and Assyria; here are enamelled miniatures and filigree trinkets which, properly examined, would teach lessons of no slight value. Nobody, indeed, can ever pretend, without imposture, to appreciate every object and example which this building holds. It is quite enough for an ordinary ambition, therefore, to have mastered, in one sense, its generalities, and in another, the specialities of a particular class. From the recital of the will of Sir Hans Sloane in the Act of Incorporation, it appears that in addition to books, drawings, and manuscripts, he had gathered together prints, medals, and coins (ancient and modern), seals, cameos and intaglios, mathematical instruments and pictures, stuffed birds, beasts, and fishes, anatomical preparations, reptiles, monsters and abortions, accumulated from all quarters of the globe; and yet amid this medley, which has been increasing year by year, what inestimable cabinets are found!—the Hatchett minerals, the splendid Hamilton volcanic specimens from Mount Vesuvius, few of which are ever inquired after, partly because the populace feels more entertained by the mammoths and beetles, but still more because it cannot grope its way into the crypts which make of the edifice rather a burial place than a museum, rather less cheerful than a cell in Newgate, and much less airy—light being out of the question, as an extravagant luxury. We pass cursorily for the moment the other classes, which are really of importance, though they may be ill located here, and are about to be removed; the mammalia, an exhibition simply of stuffed skins, so crowded that they cannot be seen to advantage, especially the great ruminant and pachydermatous animals, forming altogether a very imperfect representation of their kinds; the birds, not half of which can be seen, and which require six or sevenfold more space for their due exhibition; the reptiles, almost wholly kept out of view; the fish, and so forth. If the public knew how many pages of this huge and rich Bloomsbury book are practically closed against it, a sense of dissatisfaction might justifiably be experienced. It does not seem right, said a good authority a few years ago, that such valuable space should be taken up by Esquimaux dresses, canoes, and hideous feather idols, and broken flints called "rude knives." Each collection is a detriment to the other, and the proper remedy is that one should go. We have suggested in this opening notice that the books in the British Museum need not be brought into question. Still, as a matter concerning both the structure and the public, a few general observations may be allowed. There is an immense amount of utterly valueless and unoriginal American literature occupying shelves which are urgently wanted for other uses. The bulk of modern Scotch theology might well be boiled down to a hundredth of its actual dimensions. There is no reason why, because a volume is published by the vanity of its author, it should become a national archive. How many among the last ten thousand new novels should be allowed a monumental place in the bookcases of the British Museum, usurping so many niches in the forty miles of shelf which its librarians have occasionally boasted about? Why all the editions of Tupper? Why all the editions of Mrs. Caudle's Curtain Lectures? Why the whole of Cumming, or those myriads of petty tomes in stained calf and abraded morocco, which do not belong to literature at all? What is a library? asked the Russian Empress Catherine, of Prince Potomkin. "A book shelf," answered the Prince, "with little volumes at the top, and big ones at the bottom." We shall have better things, however, to say of the Bloomsbury establishment after this first discursive criticism.

ARTIST-ARCHITECTS.

MR. WYATT PAPWORTH is a bold man, in that, "being convinced that the 'artist-architect' is damaging the profession," he has dared at the present moment to come forward and say so. The statement however, pardoxical as it may appear, is not so devoid of foundation as many of our enthusiastic and over-noisy juniors would affirm it to be, and the question is one well worthy of consideration. That architecture is an art as well as a science, is indeed jealously to be asserted, and we are even prepared to claim the precedence of its artistic above its scientific qualities, were it at all necessary to do so. That is to say, while we look upon building soundly and strongly as the first essential, that may be done, and yet leave building a mere trade, without the slightest pretension to being a fine art at all. To build beautifully is the aim which alone lifts the craft into the higher category of art. But to dabble in what are specially the provinces of the painter and the sculptor has of late been looked upon as what alone can entitle an architect to be considered as an "artist-architect."

It is this notion which we think, with Mr. Papworth, is fraught with considerable danger, and which we fear has arisen out of vanity on the part of a few men in the profession, who fancy they have attainments which distinguish them from their fellows; because, forsooth, they can draw the figure indifferently well, they and they alone are entitled to the high-sounding name they have coined for their own advantage.

We maintain, on the contrary, that architecture in itself is an art, and a very high one, independently of all assistance from the decorator. Supporting Mr. Ruskin in the general tenor of his somewhat too arbitrary dicta, we demur to one which he has often made on this very point. He has asserted that, to take a Gothic doorway with a carved pediment, for instance, all the art in it is in the carving, and that to the designer of the framework of the same no credit is due beyond that of an able but subordinate workman. This is a wholly erroneous view, which has arisen from his taking a part rather than the whole of a building as his example, and cramping his vision accordingly. We fancy we could cull from his description of the Doge's Palace at Venice a string of laudatory adjectives which would be little applicable to the mere dollish figures which lurk amidst the leaves of the capitals of its columns, and which not even his favourite groups of sculpture on the three angles of the building could have the immodesty to appropriate entirely to themselves. Scrape off, in imagination alone if you please, all the sculptures from the mediæval cathedrals—and iconoclasts and revolutionists have done much towards accomplishing in fact the said feat—and is no art left in their mighty and well-proportioned structures?

To draw the figure is well, but it argues no power of invention or design on the part the draughtsman. It is no great credit to him, for not only every architect but every gentleman in the land should do the same, had we our will. To learn to draw is easier than to learn to write, for to form meaningless pothooks and hangers is a tedious task, which thousands, who practice it all their lives, never accomplish satisfactorily; but the veriest ploughboy, if set with a pencil in hand to use his wits by drawing what he can see and understand, is interested and made intelligent by the effort, and will, in less mouths than it would take him years to become a calligraphist, succeed in becoming a tolerable draughtsman. We do not want to know whether the man who reared the picturesque buildings around the precincts of the cathedral of Wells was a proficient in the drawing school of his day; perhaps he was a dunce in that respect by the side of the carver to whom he entrusted the carving of the terminations of the corbels he designed; but he knew how to build beautifully and picturesquely, and therefore was without question an "artist-architect."

It may be a curious archæological question, How intimate were the relations between the sculptor and architect of that grand poem in stone, the west front of that cathedral of Wells? as it is also with regard to the façade and pediment of the Parthenon at Athens. Some men in all ages are intellectual giants, but we need not frame drawing-schools for them. The design that is in them will come out, and they will know whom to direct and how to do so, if they cannot execute every part themselves. We, who are called upon to legislate, must look to the ordinary capacities of men, and to what is practical under present circumstances; and we affirm, without fear of contradiction, that there are ample facilities in the present day for the would-be artist-architects to educate themselves, if they be so inclined. At any rate, there are ten times the opportunities now than have been at the disposal of any previous generation in the world's history; and yet the cry is, while the Art Classes at the Architectural Museum are but scantily attended, for more lectures and more drawing schools; and it strikes us that the cry is as unreasonable as that would be on the part of the famishing Parisians, if they asked us English not to content ourselves with sending them the food we are doing, but to come over and spoon-feed them as well.

It will be time to design the diploma certificate for which so many enterprizing, but, as they would have it, neglected and unappreciated geniuses are clamouring, when half a dozen present themselves annually for those Voluntary Architectural Examinations which the much-maligned Institute has established already.

The last appeal we have noticed—it must be owned with some slight derision—is for a Royal Academy of Architecture. What is in a name? we feel inclined to ask—for what difference there would be between a Royal Academy and a Royal Institute we are at a loss to discover. It seems the proposer of this new scheme sees a panacea for all architectural evils in the appointment of forty high priests out of the ruck of the profession. Why this is the very blot in the escutcheon of the present Royal Academy, and the kindred artistic professions are almost in rebellion against the exclusiveness which in that case can at least plead respectable authority on the score of precedent. This is only another futile attempt to obtain protection, in a day when all systems of protection are doomed. And who, again we ask, is it that seeks such? Simply the incompetent, who fear they cannot achieve for themseves the eminence they would desire. Let their own works speak for them—the proof of a pudding is in the eating; if they are artist-architects, the world will not be slow in appreciating the art they produce. None need fear free-trade but those whose wares are not worth purchasing, or who lack the energy to make good salesmen; and though we may pity them we cannot be expected to establish ourselves, or that the public will establish for us, training schools and hospitals for incapable architects, however well-meaning and artistic they may be. J. P. S.

The paintings on the walls of Whitecross-street Prison, supposed to be by George Morland, have been damaged and defaced wilfully.

The Brighton Railway Company announce that they will open the portion of the East London line between Deptford-road and the junction with the South London line at the Old Kent-road on March 1st.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

THE eighteenth lecture of this course was delivered by Dr. G. G. Zerffi, in the Lecture Theatre, South Kensington Museum, on Tuesday afternoon last. In continuing the subject of Greek sculpture, the lecturer observed that it might be studied from the descriptions of Pausanias, Pliny, and Strabo, and from the numerous copies of Greek works to be found in the different museums. The first mythical period of Greek Sculpture, he said, had commenced with Dædalus, to whom thirteen works were attributed. These were principally busts of Artemis, Aphrodite, and Athene. It was, however, doubtful whether any such person had ever existed. Most probably Dædalus had merely been a common name applied to artists in general. Next Epejos had been mentioned by Homer as the maker of the large wooden horse employed by the Greeks in their stratagem for the taking of Troy. Dibutades, a potter, was set down as the introducer of plastic art in clay. He was said (and the legend was repeated by other writers) to have had a daughter who, having been deeply enamoured of a young man about to go on a journey, was anxious to preserve some memorial of him, and consequently drew his shadow in outline. She produced an excellent likeness, and her father filled in the lines with clay, adding the eyes and marking the hair, and was thus the first to use clay for plastic works. The ornamentation of the pediments of temples was attributed to him. Smilis of Ægina was said to have been contemporary with Dædalus, and was probably also a mythical person. In fact the name Smilis was used generally to designate a sculptor or image-carver. We had historical facts and dates only from 600 B.C. Glaukos, who had been born on the island of Chios, had first worked in metal, which he softened or hardened by fire and water. The stand of a sacrificial vessel, worked by him in bronze, was so celebrated that his name became proverbial for excellence of execution. This was ornamented with reliefs, representing plants and animals, and had resembled a truncated tower in form. Rhœkos and Theodorus had been more distinguished as metal workers. They had constructed the Labyrinth at Lemnos, in which work they were said to have been assisted by Smilis. This building had had 150 columns; to turn them out they had such an excellent mechanism that a boy could set it in motion. Theodorus had prepared the foundations of the Temple of Ephesus, and was said to have cast a figure of Night for the same building. Pliny mentions another statue which had been made by this artist, and which had represented himself. In its right hand it held a file, and in the left a quadriga or chariot with four horses, which latter had been so minute that it was covered by the wing of a fly, also worked in bronze. Though this account might be legendary, it served to show that metal work must have reached a high state of artistic development at that period. Several silver and golden sacrificial vessels, and a golden vine with the grapes made of precious stones, had also been attributed to the same artist, who was further said to have invented the square, the level, the turning-lathe, and the key. He had been the first to lay down theoretical rules for the guidance of future artists in a work on the temple of Hera at Samos. The family of Melas, of Chios, had been the first to work in Parian marble. Bupalos had distinguished himself by making a Tyche for Smyrna, with the Polos on her head and the horn of Amalthea in her hand, creating the model for the future representations of the goddess of fortune. Byzes of Naxos had been the first to cut marble into thin slabs for architectural purposes, and provided marble tiles, with which the temple of Zeus at Olympia had been covered. Cheirisophorus and Bathykles belonged to this period. The former had made an Apollo, said to have been of gold, but which had more probably been of wood covered with thin gold plates. The latter had constructed a throne of Apollo, the reliefs of which showed a kind of symmetry. The back had been ornamented with a chorus of Magnesians. In all, few examples of the style of this period existed. The reliefs from the temple at Assos (now in the Louvre), were unmistakeably in the Assyrian and Egyptian style. Two of the metopes of Selinunt at Palermo were well preserved. On the one, Perseus was represented in the act of slaying Medusa, and on the other Hercules carrying two Kobolds or Kerkopes hanging from a pole. Though in these the execution was coarse and faulty, yet we found in them signs of that dawning power in grouping which distinguished Greek sculpture. The material used was limestone, and the remains of colouring were to be perceived on the seam of Athene's dress. In the Glyptothek at Munich there was the statue of an Apollo, from Tenea, which was in marble, and life-size. The anatomy was perfect, but the mouth grinning, the hair thick and falling in waves on the shoulders, the forehead receding, the eyes wide open, and the nose strongly protruding. This work afforded an example of the Dædalian statues. In the year 1864 a fragment of a Hermes of hymetic marble had been discovered on the eastern side of the Akropolis at Athens. It much resembled the above-mentioned figures in style. In the museum of the Theseus temple at Athens, the tombstone of Aristion, the work of Aristokles, was preserved. The figure was that of a Hoplite, or man in heavy armour. A similar tombstone had been found near Orchomenos in Bœotia. It was of grey marble, and represented a citizen wrapped in a long cloak leaning on his staff, whilst his dog jumps at a locust which he holds in his hand. According to the inscription this was the work of Auxenor of Naxos. A beautiful relief of this period found at Melos was now in the British Museum. It was in terra-cotta, and formed a charming group. We had before us Alkæus the poet, who is deeply in love with Sappho, and who appears to whisper that he wishes to tell her something, but bashfulness prevents him. She seems to reply that if a beautiful and noble feeling inspires him, and if he were not bent on saying something wrong, he would not cast down his eyes ashamed, but would speak boldly. This scene was executed with great truthfulness by the sculptor. Ten statues from Miletus were also in the British Museum. They were all above life size, and had formed an avenue of sculptures lining the sacred road from the harbour to the temple of Apollo. The style was monumental. The hands rested on the knees, the bodies were heavy, shoulders broad, and the forms, especially those of the women, round. Only one statue had a head, the face of which bore the usual broad grin; the ears, however, were well shaped. The upper and under garments were of the usual kind, the former falling in vertical, and the latter in curved and horizontal lines. Having drawn attention to some further examples of the style of this period, the lecturer went on to say that the next epoch commenced when the political life of the Greeks had taken more decided forms, and the social condition of the people had been greatly improved. The seven wise men had begun to influence the masses with their practical philosophy; a spirit of criticism pervaded literature; and epic poetry yielded to lyric. It was consequently not surprising that at this time Art should have been inspired with a new spirit. Passing over Kanachos, after whom we had an Apollo in the British Museum, we came to Ageladas (515 B.C.), who had been the master of the three greatest sculptors of Greece: Phidias, Myron, and Polykletus. Were nothing further recorded concerning him, this alone would be sufficient to render him immortal. At Argos, where he lived, he had founded a special school. Two of his works representing Zeus as boy and as man were worthy of praise. Both Ageladas and Onatas had worked principally in bronze, with great power. Onatas had been celebrated for having wrought the Demeter Mekena near Phigalia in bronze, which replaced the old wooden image which had been destroyed by fire. Not less excellent had been his Herakles, ten yards in height. The Demeter just mentioned was the only female figure attributed to him, he having confined himself to the representation of heroes; he also excelled in reproducing horses. Turning to Athens, we had Antenor, who made the statues of Harmodius and Aristogeiton. This group had been taken away by Xerxes (480 B.C.), and a new one had afterwards been sculptured by Kritios and Nesiotes. We might find fault with the stiffness of the execution, which was too faithful to be really beautiful, but the composition was full of life and the arrangement masterly. We were better able to judge the artists of Ægina of this period, as we possessed from the pediment of the temple of Minerva two groups, which had been restored by Thorvaldsen and were now in the Glyptothek at Munich. Of the western group ten of the statues were perfect, the eleventh much damaged. Of the eastern group five statues only were in good condition. Of the former Onakas had probably been the artist, but the latter was so superior that it must be assumed to have been the work of another artist. It was attributed to Kallon. The productions of Kalamis, Myron, &c., will form the subject of the next lecture.

MOORE'S PATENT WATER-PIPE PROTECTOR.

THE unwelcome visit of the plumber to stop the too liberal water supply in our houses has been an incident of unpleasantly frequent occurrence during the late severe frosts. An arrangement has been recently patented under the above title for the prevention of this domestic nuisance. Certain valves and cocks are connected with the pipes, which, that they may be *self-acting*, are weighted in such a manner that when left to themselves and unsupported, they immediately shut off the supply of water and empty the pipes. They are prevented from doing this in ordinary weather by being suspended from a small tube of glass containing water, and specially manufactured for the purpose. As soon as a sharp frost occurs it attacks this glass tube, the water within which quickly becoming frozen, expands and bursts the tube. The weighted valves and cocks thus losing their support immediately fall, shut off the water supply, and empty the pipes. The frost thus becomes the active protecting power of the pipes, instead of as heretofore being the cause of injury to them. The apparatus cannot fail, it allows water to be easily obtained from the pipes during the continuance of the frost, and on its cessation the trifling cost of the renewal of the glass tube again effectually guards against the enemy. The apparatus is manufactured by Messrs. Guest & Chimes, of Rotherham, and may be obtained in London of their agent, Mr. Thomas Beggs, 37, Southampton-street, Strand.

BUILDING NEWS SKETCH BOOK.

THE "Sketch Book" series is now finished, and we beg to tender our thanks to the many gentlemen who have contributed to it, and also to the equally large number who have sent sketches which have not appeared. Had many sketches which have not appeared been sent in earlier, they would have been substituted for others which have been published. We shall defer making any observations on the merits and demerits of the sketches till the awards of the adjudicators are given. The prizes are £10 10s. for the best drawing; £7 7s. for the second; and £5 5s. for the third. The contributors are to be the adjudicators, as mentioned in No. 756, July 2, 1869. We then said—"In order that there may be no complaint of unfairness in the award of the prizes, we propose that the contributors shall decide for themselves; each contributor to have three votes, or a vote in the awarding of each prize, but no contributor shall be eligible to vote for himself. The author of the sketch who has the most votes will have the first prize, the author who has next to the most will have the second prize, and the one who has the least number of votes will have the third prize." We now await the decisions of the umpires, and shall be glad to receive them as soon as possible. Should any two contributors have an equal number of votes, Mr. J. P. Seddon, the Hon. Sec. of the Institute, has consented to act as arbitrator and give a casting vote. We should have said that fifty-nine sketches have appeared, which, with the frontispiece, kindly contributed by Mr. P. Auld, will make sixty.

LAXTON'S PRICE BOOK FOR 1871.

LAXTON'S has *always* been recognised as *the* Price Book, not only by the trade, but by the various Law Courts, by whom reference to it is always made as the acknowledged standard. Its fifty-fourth edition is published by Messrs. Kelly & Co., who have thoroughly revised and re-arranged it, and made many useful additions. The issues for the past few years have hardly sustained the character of the book, but the trouble at which its present publishers have been to more than restore it to its old position cannot fail to be appreciated. The contents comprise over 72,000 prices of various materials, carefully corrected according to present rates and wages, together with a variety of other useful information,

NATURE IN ORNAMENTATION.*

SAVAGES use generally only geometrical figures in the ornamentation of their vessels, weapons, oars, clubs, cross-beams, or door-posts. The triangle, the square, the circle are applied in a thousand different forms, windings, and combinations. As soon as man frees himself from the savage state he takes his motives for ornamentation from the vegetable kingdom. Plants and flowers have formed for the last six or seven thousand years one of the principal elements of ornamentation. We may trace two different methods in the use of the types of organic nature by ornamental artists. There are some who regard as paramount only the ornamentation of their work; they use the vegetable forms as means to attain an aim. The vegetable products are either changed or transformed, just as the ornamentalist thinks it best fit for his purpose. Above all, he observes symmetry and order as the two essential elements of ornamentation. This artist raises himself above Nature. Her products are used by his intellectual powers at his will. This method of handling the products of the vegetable, or even animal kingdom, according to the imagination and intentions of the artist, produces "style," which often has varied, as may be studied in the history of art. There are others who altogether disregard the object which they intend to ornament. They have only one aim, which they strive to attain—a correct, faithful, and most accurate imitation of the organic products of nature. They delight in reproducing the defects, deformities, and peculiarities caused in plants by wind, frost, or rain. A dew-drop on a rose, a worm-eaten leaf of a tulip, are the very highest aspirations of these so-called "naturalists," who have a tendency to use nature in her unadulterated condition for ornamental purposes. Art with these men becomes subservient to Nature, which is, in itself, contrary to all principles of art. If ornamentation does not grow out of the very character and form of the work to be ornamented, it is in itself a nonentity. But Nature with them is everything. What could there be more beautiful than Nature? These artists do not see that Nature is beautiful in adorning a prairie with a variety of flowers, but that if those flowers are transferred on a frieze, or on the legs of a table, a plate, or carpet, or the paper covering the walls of a dining or drawing-room, the ornamentation becomes altogether out of place and order. We come, therefore, to the conclusion that forms and products of Nature can only be used for ornamentation under the regulation of a correct style. The naturalist turns into an imitating, or rather mimicking, slave of Nature, and is incapable of doing justice to the requirements of art. The artist, with a style of his own, frees himself, above all, of Nature. He takes her forms, sifts them, and uses them according to the faculty of his imagination, but detaches them from their connection with Nature, and elevates them to real products of art. Thus only he is enabled to fulfil all the conditions with regard to colour, form, arrangement, and distribution over space, in strict harmony with the object he intends to ornament. To bring plants into conventional forms was the tendency of all good ornamentation from time immemorial. It is a curious fact in the historical development of ornamentation, that the more we trace back our steps in the investigation of ornamented works of art, we find the conventional treatment of plants and animals practised. One would suppose that a close imitation of the forms of Nature ought to have been the first natural impulse of man; but this is not the case; on the contrary, whether we look on Assyrian or Egyptian ornamentation, we find that a conventional treatment of the forms of Nature was universal; and only a modern school of ornamentalists tries to bring decorative art, by a slavish imitation of Nature, to a kind of conclusion, and to bar the way to further original forms and combinations. Though the conventional treatment of natural products has been the basis of good and correct ornamentation, the very treatment of the types of Nature has varied in different countries at different times. This is the reason that we see in the history of ornamental art an everlasting change, which is the more interesting as it is not so much the result of the individual artist's will, as rather the characteristic peculiarity of some settled style, which in its turn is the effect of the national sentiment—the tendencies of a period and the degree of taste in art at a certain epoch of the life of a whole nation. As a proof of this statement, we have, above all, Egyptian art; we certainly know it only when already highly developed. The Egyptian art had not been altogether the product of pure artistic motives; it was not an unfettered art, devoted to the laws of beauty alone, subordinating everything to higher aspirations. Egyptian art was the faithful servant of religion; symbolism was its element. Symbolism chose for the artist the special plants which he had to use for ornamentation. Though symbolism went so far as this, the manner of the reproduction and combination of certain plants was still left to the free will of the artist, and therein the Egyptian products of art deserve our careful study. The elements of Egyptian ornamentation are exclusively the lotus and the papyrus, to which we must add the palm tree. Symbolism meant by these forms to teach the masses that body and intellect ought to have their proper nourishment. In looking at the ornamental reproduction of these plants in Egyptian art, we find that though they resemble their originals they are anything but what Nature has produced. Deprived of all special individuality, the plants are brought into a regular symmetrical form; all their details, as the bud, the stem, and the flower, are generalized. The plants may be united in rows; if so, they are arranged enrithmically, in double rows, with alternating higher and lower plants; or in fan-like radiation, to a certain degree repeating the form of the single flower. Flowers are sometimes represented as rising from the water. In those instances they rise regularly, at well measured distances, with a perfectly similar form and growth. The waves themselves assume symmetrical and uniform lines. Kings presenting plants to one of their divinities as a grateful offering, hold them not in the natural shape in their hands, but in the usual conventional, artistically remodelled form. The ornamentalist was guided in such cases by a correct feeling, for had he made the plants in these isolated instances in accordance with their natural forms, he would have produced a striking discord; and this he carefully avoided. But how did it come that the Egyptian artist has deviated with such correct feeling from what he saw in Nature? It could not have been a mere fancy, which originated in nothing, that developed itself into a national style and continued as such for thousands of years. The Egyptian must have observed in Nature law and symmetry, according to which he regulated his own existence, submitting to them also his productions of art. Nature taught him to make himself acquainted with general types of certain plants, and to disregard the individualisation of the single plant—and he did so. By this means of generalization, he learnt that there are laws in Nature under which you may bring the plant with its outlines, the formation of its flower or fruit; he must have observed that the same law ruled the relation of the leaves to the stem; that certain principal lines and outlines all spread regularly from one central point. He took thus nature in her symmetrical perfection as a model, freeing her from all accidental inaccuracies or deviation; and this perfection with its immutable order turned out to be to him the very law of art. Placing thus the plant in profile, arranging the flower and the stem as two connected totals, distributing the lines to the right and the left in symmetrical order, he did not altogether lose the basis of Nature; he only idealised Nature. There is scarcely a style in which the right principles of correct ornamentation are so well expressed as in the Egyptian. The types of the plants are the result of a keen observation of Nature. By the great severity of his customs the Egyptian artist was hindered from cultivating a freer mode of combination, and the symbolism to which he was subjected forced him to be contented with a few plants. Nature, however, is inexhaustible in her products which may serve, if properly understood and carefully adapted, for ornamental motives. The Assyrians and Persians appear to have had some older style which they copied; and there is to be observed a kind of settled and inherited conventionalism in their motives of ornamentation. Nature appears scarcely recognisable in their decorative forms; but they were less fettered by symbolism than the Egyptians, and we may trace some new motives in their works of art. The flowers are not represented in profile but in full; we have with them the use of rosettes, which have been adopted probably later by the Egyptians too, though with them the origin is much more of a geometrical character than with the Assyrians or Persians, who apparently worked from nature.

In my next I intend to consider Nature in ornamentation with the Greeks.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

ON LIMES AND CEMENTS.

AT the last meeting of this Society, on the 3rd inst., Mr. J. E. Walton, A.I.C.E., President, in the chair, two papers on this subject were read, the authors being Messrs. R. M. Bancroft and H. E. Hunt. We give abstracts of each:—

MR. BANCHOFT'S PAPER.

The author commenced by pointing out that calcium is the metallic basis of all limes. Rich limes are yielded by limestones containing from 1 to 6 per cent. of foreign substances, such as silica (flint), alumina (clay), magnesia, iron, &c. Soft chalk, hard ragstone, or marble yield equally good lime, since the calcium they contain is the same mineral. Chalk, however, generally contains water irregularly distributed, and not exhibiting the same change that marble or stone does; it is frequently unequally burned, and therefore slakes imperfectly. The purer the lime the finer should be the quality of the sand, the pure limes requiring finer, and the cements a coarser sand than the hydraulic limes. Poor limes are those which either do not increase in bulk, or only do so to a trifling extent, when slaked. They are all obtained from limestones which contain silica, magnesia, manganese, or metallic oxides; these foreign substances are present in poor limes to the extent of from 15 to 30 per cent. They do not slake freely, and are liable to vitrify in burning. Limes from limestones containing much silica swell in setting, and may dislocate the masonry executed with them. If alumina be in excess the lime is likely to shrink and crack. If carbonate of magnesia be combined with carbonate of lime, as is the case in magnesian limestones, the original bulk is retained. All limes which fall short of from 10 to 18 per cent. of clay should be rejected. Grey limes from the Medway containing about 18 per cent. of clay make good mortar. The blue lias stones have long been reputed to be the best of all English limestones. They are mostly found in the British Channel, at or near Watchet, in Somersetshire, at Aberthaw (near Cardiff), and at Lyme Regis and Barrow. Blue lias is a limestone particularly serviceable for concrete and all works connected with water. Greystone lime—the lime principally used in the buildings of the present day—is simply limestone burnt in a kiln, as chalk is burnt. It is to be obtained either ground or in the lump, the ground lime being used for concrete. About 1s. 6d. per yard of eighteen bushels is usually paid for

grinding. The same object could be attained by simply slaking instead of grinding. Chalk-lime mortar requires two parts of lime to three of sand, and is chiefly used for plasterers' work. It is mixed with cow-hair, and put on in one or two coats, and finished with a thin coat of lime, thoroughly run down and reduced to a pulp, technically called "fine stuff." In damp situations or trenches not well drained, if chalk lime is used in making concrete the concrete will never set, and if there is any running water in course of time all lime gets washed out of the ballast and dissolved away. Chalk lime never should be used in damp situations. The author next proceeded to speak of mortar, and deprecated the entrusting its mixture to mere labourers. He also insisted upon more time being allowed for the mortar in new work to get hard before piling upon it any great weight of superstructure. In work hurriedly run up nothing was so common as to see settlements and cracks arising solely from the compression of the mortar before it had had time to harden. In making mortar, from seven to three parts of lime of the ordinary sort are usually mixed with two parts of sand—the stronger the lime the more sand it will take, and the more sand used the slower, as a rule, will be the setting, but the harder the mortar. The hardness of the limestone from which the lime was produced has nothing to do with the hardness of the mortar; it is its chemical composition which regulates the quality of the mortar. Lime should be used as fresh and stiff as possible, and the bricks or stone should be well wetted with water, particularly in hot weather. It is important that all water used for making mortar or cements should be free from all impurities of vegetable and organic matter. With regard to hydraulic limes, the admixture of pulverised *forge scales*, or iron dross, with calcareous matter makes a very strong hydraulic mortar. The Dorking, Marsham, and Halling limes are largely used as hydraulic cements. A good mortar may be made of three measures of sand, and one measure of Dorking or Halling lime. Blue lias stone lime requires twice its measure of sand. A measure of lime is 27 cubic feet, and it contains 21 striked bushels. Keene's cement is capable of being worked to a very hard and beautiful surface. It is obtained by soaking the plaster in alum water after a first calcination, it is then put a second time into the kiln, re-burnt, and ground. Parian cement, like Keene's, also has a plaster base, the gypsum being mixed with borax in powder, and the mixture is calcined and subsequently ground. Scagliola is made of plaster of Paris and different earthy colours, which are mixed in a trough in a moist state, and blended together until the required effect is produced, when the composition is taken from the trough, laid on the plaster ground, and well worked into it with a wooden beater and a small gauging trowel. When quite hard, it is smoothed, scraped, and polished, until it has the appearance of marble. Plaster of Paris is used for cornices and internal decorations, and is the base of all the internal decorative cements known as Keene's, Parian, Martin's &c. It is partly soluble in water, and therefore unsuitable for any but inside work. Stucco is plaster and lime mixed together. It is generally made of lime, mixed with calcareous powder, chalk, plaster, and different other substances, in such a manner as to obtain in a short time a solid surface. Bastard stucco is a three-coated plaster—the first generally "roughing in" or "rendering," the second "floating," as in trowelled stucco; but the finishing coat contains a little hair besides the sand. It is not hand-floated, and the trowelling is done with less labour than in what is called trowelled stucco. In stucco for external purposes such materials only should be used as are capable of resisting the action of wet. Rough stucco is a mode of finishing staircases, passages, &c., in imitation of stone. It is mixed with a large proportion of sand, and that of a coarser quality than trowelled stucco, and is not smoothed, but left rough from the hand float, which is covered with a piece of felt to raise the grit of the sand, and so give the work the appearance of stone. Pozzolanos are principally composed of silica and alumina with a little lime in combination, mixed with potash, soda, magnesia, and oxide of iron.

MR. HUNT'S PAPER.

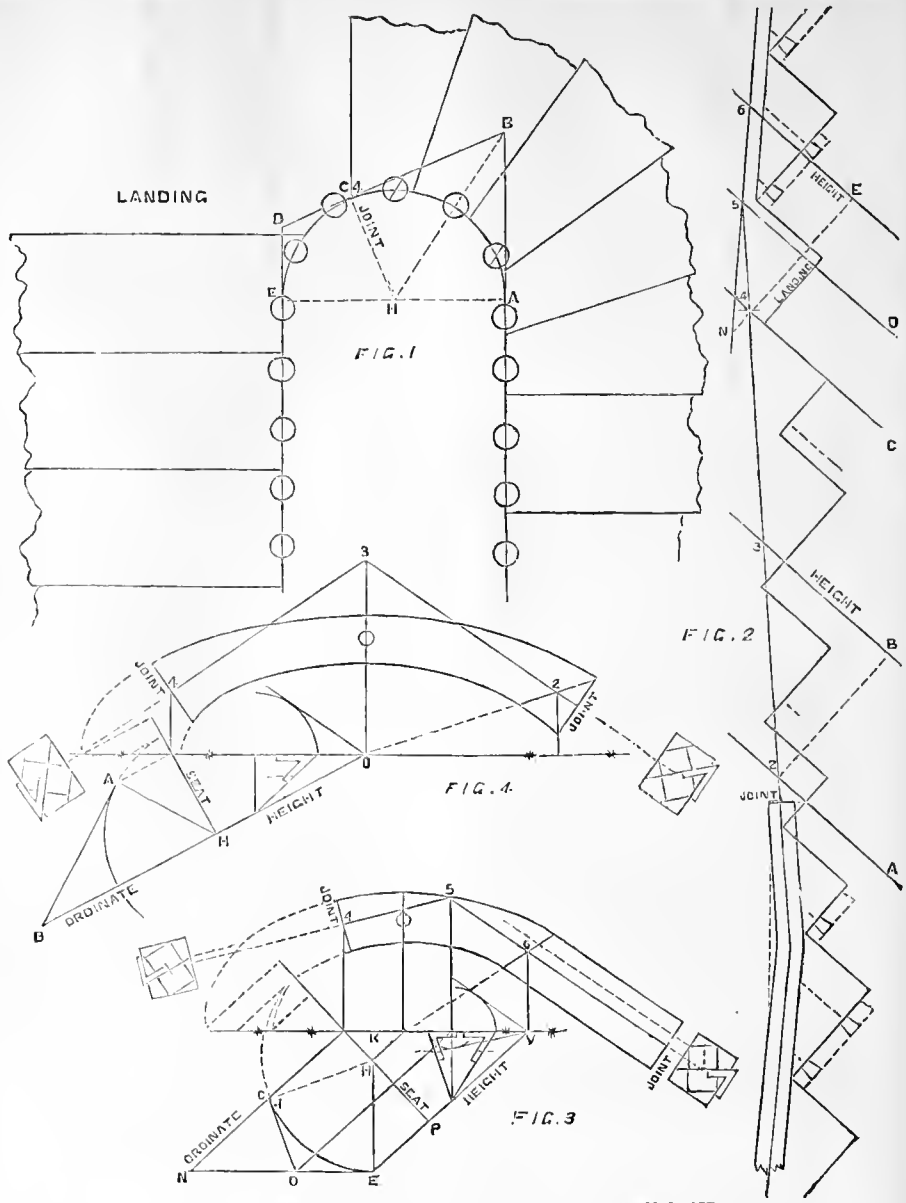
Mr. HUNT commenced his paper by a reference to the causes which act in giving some limes the power of setting under water. He observed that Smeaton, when engaged in the construction of the Eddystone lighthouse, found that all lim s that set under water were obtained from the calcination of limestones which contained a portion of clay in their composition, and his experiments led him to use a cement composed of Aberthaw lime and of Pozzolano. That Smeaton was right in the selection of his stones was almost certain, though perhaps he did not quite recognise the important part which the presence of clay (or silica and alumina in chemical combination) had in the result which he obtained. Referring to some tables exhibited on the walls, containing analyses of the best hydraulic limes, Mr. Hunt observed that such limes almost all possessed the same bodies, though in varied proportions. Limestones or calcareous stones (or those stones containing carbonate of lime) are of very various natures. There are, for instance, pure carbonates of lime (some of which are perfectly crystalline, as marbles), and others which contain, in addition to the carbonate of lime, magnesia, oxide of iron, manganese, silica, and alumina. The name limestone is generally applied to those stones containing at least 50 per cent. of carbonate of lime. A mere chemical analysis of a sample does not always give the results that are obtained by practice. Experience alone is the best guide in this matter. The existence of carbonate of lime in stones is easily detected by the application of dilute nitric or muriatic acid; by the effervescence which takes place, caused by the escape of the carbonic acid gas from the carbonate of lime, pure lime is left behind. The next most important substance which enters into the composition of limestones is silica, which exists very nearly in a state of purity in flints, common quartz, agate, &c. It is not sensibly soluble in water or dilute acid, but dissolves freely in alkaline solutions at a temperature of from 300° to 400° Fahrenheit. The next and last substance that plays any important part in limestones is alumina, which is recognisable in the form of common clay, but not then in a pure state, but in chemical combination with silica. None of the other bodies, except magnesia, are of any value as regards the hydraulicity of the lime. Chemical analysis shows that the stones which contain only from 1 to 6 per cent. of silica, alumina, magnesia, iron, &c., either separately or in combination, give rich limes upon being burnt. Limestones containing insoluble silica in the shape of sand, magnesia, oxides of iron, and manganese, but limited to between 15 and 30 per cent. of the whole mass, yield poor limes. Limestones containing silica in combination with alumina, magnesia, and traces of oxide of iron and manganese in various respective proportions, but within the limits of from 8 to 12 per cent. of the whole mass, yield moderately hydraulic lines. When the foregoing ingredients are present in the proportion of from 15 to 18 per cent., but the silica in its soluble form, the limestones yield an hydraulic lime. When the limestone contains more than 20 and up to 30 per cent. of these ingredients, an eminently hydraulic lime is yielded. Limes owe their hydraulicity to the presence of a certain quantity of clay, and sometimes, though rarely, to that of a certain quantity of soluble silica. It is supposed that during the calcination, silicates of lime and alumina are formed, with an excess of lime; these, in slaking, absorb a quantity of water, and solidify in combining therewith, and the double salt being insoluble in water, the compound remains therein without decomposing, or at least only yields that small excess of lime which might have existed in the combination. Rich limes are the purest limes we possess, and the purer the carbonate of lime from which they are obtained, the more distinct are the appearances from which they take their name. These are that they augment in volume to twice their original bulk (or more) when slaked in the usual manner. If employed by themselves without any admixture of foreign substances, their consistency is the same after many years of immersion as on the first day. Poor limes do not augment in bulk at all, or only do so to a very trifling extent when slaked. They do not harden under water more than rich limes, and are acted upon by that agent in nearly the same manner. The middlingly-hydraulic limes set under water after from 15 to 20 days' immersion, and continue to harden for some time afterwards, but the progress of their hardening diminishes after the sixth or eighth month; after a year their consistence is equal to that of dry soap. The change of bulk they undergo in slaking is about the same as that of the poor limes. Hydraulic limes set after from six to eight days' immersion, and continue to harden; the process of solidification may extend over twelve months, although the greater part is completed by the end of the first six. Eminently hydraulic limes set within the third or fourth day of their immersion. After a month they are quite hard, and capable of resisting the dissolvent action of running water. No limestones are capable of producing in a commercially valuable form hydraulic limes unless silica be present in combination with alumina. All experiments go to show that, in the proportions cited, it is the most efficient agent in producing the hydraulicity. Mr. Hunt next proceed to speak of the calcination of limes, after which he enumerated and described some of the best known hydraulic limes of the country. Firstly he named the Aberthaw lime, the chemical analysis of which is as follows:—Carbonate of lime, 72·91; alumina, 7·18; silica, 10·74; oxide of iron, 1·77; moisture, &c., 7·40 = 100·00. The best proportions for hydraulic mortar are from 2 to 3 parts of sharp sand to 1 of lime. If the lime be used for concrete, 6 parts of shingle, or even more, may be used. When the lime is used for concrete under water it should be mixed up for some hours prior to its being placed in the foundations. It usually requires a day to be set under water. This lime was used by Smeaton for the Eddystone lighthouse. The price, delivered in London, is 22s. 6d. per ton. Another powerful hydraulic lime is that made from the Halkin Mountain limestone, and which was exclusively used by Jesse Hartley, in the construction of the Liverpool docks. The analysis of this limestone is: Silicia, 21·56; carbonate of magnesia, ·80; alumina, 1·16; oxide of iron, ·50; carbonate of lime, 72·60; water, &c., 3·38 = 100·00. This lime has very great power of setting under water. In rubble masonry and backing up for dock walls, the proportions are: 1 part lime, 2 of sand, and ¼ of smithy ashes, ground for twenty minutes. The best mortar for foundations, sewer bottoms, pointing, &c., is made up of 1 part of lime, 3 of sand, and ¼ of ashes, ground forty minutes. The most extensively used hydraulic lime of all, however, is the blue lias. Its chemical analysis is: Lime, 45·50; alumina and silica, 18·50; carbonic acid, 31·50; water, 4·5; = 100·00. The best quality in this large bed is to be obtained from the quarries in Warwick. The best proportions of lime to gravel for concrete are 6 to 1 if the gravel is good, and in ordinary weather; for mortar, 2 or 2½ to 1. The mortar is not of itself sufficiently hydraulic to set under water, but if allowed to remain for 24 hours, the water has no effect upon it whatever. In conclusion, Mr. Hunt dealt with the manufacture and use of cements, and entered into the question of the relative strengths of the different varieties.

DISCUSSION.

In the discussion which followed the reading of Messrs. Bancroft and Hunt's papers,

Mr. C. H. WHITAKER, who had conducted a large series of Government experiments for Mr. Grant, exhibited some very interesting tabular diagrams, and gave to the meeting an explanation of the objects sought to be attained in each experiment, and the mode of conducting them, with the deductions he had arrived at from the results obtained. Mr. Whitaker said that Mr. Grant's tables (published in the "Minutes of the Proceedings of the Institution of Civil Engineers") showed that the tests of strength of neat cement and of cement and sand proceeded very regularly and in the same increasing ratio from one day to one year or more. At from one to two years, Portland cement appeared to attain its maximum strength, at which it continued to remain without either increase or diminution. Portland cement gauged in a mortar-mill for half an hour with the expectation of a higher result than from ordinary hand-gauging (on account of the more probable intimacy of the mixture of the cement and water) showed the cement, however, to set hard, but very brittle, the highest test being less than half that of the same cement gauged at the same time by hand. Mr. Whitaker suggested to Portland cement manufacturers whether it would not be possible to make cement of two different qualities—the one such as we know, hard, and capable of great sustained pressure, like cast-iron, for instance; the other not, perhaps, capable of bearing so high a test of the ordinary kind as the first, but, being of a somewhat elastic nature, able to sustain a sudden blow (as wrought-iron), such as the impact of a wave; and, further, whether it was not probable that cement of this kind (though according to the present system

of testing not so good) would be better suited to marine works, breakwaters, and similar structures. With regard to the adhesive power of different kinds of bricks with cement, those bricks whose porosity was the greatest were (as might be imagined) as a general rule found to hold the cement best. Stock bricks undoubtedly had the greatest power of adhesion to cement, but being more friable, broke at a point lower than that arrived at with some of the denser bricks, such as the Suffolks, Fareham reds, &c., one brick of either of which sort would readily absorb 1lb. of water. In each of these cases it was the brick itself which most often gave way, particularly the stocks. But as it was the *bricks* and not the *joints* which were broken and registered when this kind of fracture occurred, the relative adhesive value of each was not obtained, though it appeared to him most probable and most reasonable that the stocks would stand highest. There was no better brick for making sound work, especially in water-work, underground, or in damp situations. The experiments he had conducted tended to show that the stock-bricks bedded in cement set 18 per cent. stronger in water than in air, whilst all the other kinds, except some of the Galt bricks, set better in air than in water. He was not able to give the meeting any information as to the setting of *limes in water;* but a mortar composed of one part of blue lias or Dorking lime, and two parts of sand, seemed to be of about an equal strength with Portland cement compo made in the proportion of three to one. With regard to different kinds of Portland cement concrete, various materials had been tried, as broken glass, flints, pottery, Portland stone, and granite, as well as ordinary river ballast. The blocks were made of two different sizes, viz., 12in. cubes, and 6in. cubes, one set of each being kept in water and another set in air for one year, when they were tested by crushing in a hydraulic press. The Portland stone concrete gave uniformly the highest results, that made in the proportion of 6 to 1 breaking at a pressure of nearly 1 ton per square inch. The sharp angular pottery and broken flints were the next highest in the scale. The granite did not come out so well, and the ballast showed the lowest breaking strain of all, giving an average test (at 6 to 1) of about 0·60 ton per square inch. The broken Portland stone appeared to be completely incorporated with the Portland cement, the whole becoming one homogeneous mass, the stones not tearing away from the cement when broken, but the entire block crushing together through stones and cement alike. The rough biscuit-like edges of the broken pottery gave to that material a similar character to the Portland stone, though in a less degree; and the sharp angularities of the flints, with their rough calcareous portions, gave to the concrete made with them the strength it was found to possess. The granite concrete appeared to have a tendency to crumble somewhat, and the round pebbly nature of the ballast giving the cement less hold on the particles of stone seemed to be the cause of its sustaining a less load than the other concretes experimented upon. Of a large number of tests of ballast concrete (being that most generally used), the strength varied most uniformly, according to the proportion of cement employed. One interesting fact which came out was that the larger cubes (12in.) set in water stood a greater weight than those set in air, but the small blocks (6in.) were stronger set in air than in water. It was suggested that concrete made dense by compression would stand a greater pressure than that made in the ordinary way. With this view duplicate sets were made similar to the others in every respect, with the exception that the materials were rammed into the moulds by hand-beating with a mallet, getting thereby more material into a cubic foot than when only thrown in and left to settle in the ordinary manner. The result showed that these blocks formed by compression broke at an average of 30 per cent. greater strain than ordinary concrete, leading one to infer that, could a still greater pressure be applied, and greater density thereby obtained, a still higher result would follow. Mr. Whitaker said that Portland cement was undoubtedly the best for joints in any case, but that in tide-work, or where only a short time elapsed between the bedding of the bricks or stones employed, it was a good plan to strike the Portland cement joints as usual, and then point them on their extreme outside with a thin layer of Roman cement, which, setting immediately, would protect the Portland cement joint until it was completely set and needed no further aid from the Roman cement, which might wash off at leisure. Mr. Haughton, Mr. Williams, Mr. G. Eades Eachus, Mr. Meakin, and others having taken part in the discussion, Messrs. Bancroft and Hunt briefly replied, and the meeting adjourned.



NEW ELEMENTS OF HAND-RAILING.—PLATE XXII.

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page* 108.)

PLATE 22.—CONSTRUCTION OF WREATH FOR STAIRS HAVING WINDERS, QUARTER LANDING, AND SQUARE STEPS.

THE upper part of wreath forms its own ramp.

Fig. 1. This plan exhibits joint thrown from centre, making tangents A, B, C, D, E which form acute and obtuse angles. Centre line of rail struck with radius of nine inches.

Fig. 2 shows tangents, winders, and square steps, spread out. Letters along margin correspond with those on plan.

Commence, as usual, by letting under side of rail rest on square steps.

Set off half its thickness, cutting through 5 on upper part. Then 5 is a fixed point and stands over D on plan.

We now want pitch over the winders, which must be drawn in such a manner as to make a proper ramp. Assume 5.2. This makes lower part of wreath have equal pitches. When such is the case, one-half the height is sufficient for construction of mould. For example: Square over 2 B. Then B 3 gives it.

Height for upper piece of wreath is obtained by drawing through joint 4, cutting at E, giving E 6. The direction of ordinate being E N.

Transfer this to Fig. 3, where corresponding letters are shown. Square over E H. Let this equal E H on plan. Make tangents E, D, C agree with those on Fig. 1.

Draw ordinate through C. Make the seat square with it. Draw lines from D and E parallel with ordinate. Make P V, the height, equal that of E 6, on the right. Join V K extended. This is the pitch, and the major axis.

Find the length of elliptic curves; also points to insert pins for striking mould.

See that 4, 5, 6 agree with corresponding figures on pitches to the right. The straight shank of wreath may be any length desired. The dotted line from corner of rail and on surface plank shows the slab that must be cut off, according to bevel.

Fig. 4 is the mould for lower piece of wreath. It has been stated that when pitches are equal, and tangents on ground plan make a right angle, then the ordinate is always the diagonal of a square.

Here the tangents on plan show the acute angle, meeting at B. Then the sides give the right angles A H and C H. Join H B, and we have the ordinate.

This makes the construction very simple.

Commence at Fig. 4, by drawing a line in any direction; say that marked "Ordinate and height." Let B H agree with similar letters on plan. Square over the seat from H. Draw curve to equal that on plan. Have B A agree with A B on plan. Draw from A to cut seat, and parallel with ordinate. Let H O, height, equal that of B 3 on right. Draw from intersection of seat through O, and we have pitch and major axis.

Find length of elliptic curves, as usual.

The drawing is now ready to strike the mould.

Its tangents are 2, 3, 4, and must equal corresponding figures on the right.

The pitches here being equal, one bevel answers for both joints.

* This series of articles is a reproduction of ROBERT RIDDELL'S work on the subject, published in Philadelphia, and by Trubner and Co., London.

THE SOCIETY OF FEMALE ARTISTS.

THE sixth annual exhibition of this society since its re-organization in 1865 is now on view, and is characterised, perhaps, by more merit than it usually attains to. It is a great pity that it is restricted to female artists only, for if it were open to all painters alike, a few artists of note might be induced by their natural gallantry to exhibit, and thus the character of the collection would be raised. Why should men be excluded? Are women shut out from other exhibitions? If the male community are excluded on the ground that they have had a better art education, and possess superior brains to the softer sex, then this society would be better employed in working tapestry, making jams, or drying herbs, like our grandmothers, in which branches of art their talents are universally conceded to rise above those of the male sex; but if, on the contrary, as we hold, they are able to compete with men, certainly in landscape painting (and in many cases in genre painting) on an equal footing, why not admit works by known painters, or why not throw open the exhibition to any who may like to send, preserving only female members and a female council and committee? We are confident that if the ladies would follow this bit of advice, they would soon have a more popular exhibition and a more lucrative one, and in time might, perhaps, be able to give their wall space instead of letting it. The oil-paintings of the collection occupy but one wall of the room, perhaps the most important among them being that by Mrs. E. M. Ward, entitled "Going to Market, Picardy," No. 416. Despite a certain (what in the absence of a better word we must call) vulgarity in the colour and composition, this work has the advantage of many pictures here by the power of manual skill with which it is painted. A country girl with a basket on her arm containing dead poultry, clad in the wooden sabots and picturesque cap and costume of a French peasant, is dragging an unwilling little calf from the pleasant shelter of the farmyard to meet its doom at the neighbouring market town. Rather a pretty bit of summer scenery comes in on one side of the picture. Following in the school of Mrs. Ward, are two bright little works by Mrs. Crawford, No. 346, "Industry," a little maiden busily sewing away on a tiny red mat, with all her natty work arrangements by her side, really a very pleasant bit of colour; and No. 371, "Idleness," the same little girl, only with her face fully turned towards you, playing with a kitten. No. 365, "Deserted Church of S. Etienne, Rouen," by Margaret Rayner, is a very good study; the light coming in through the quaint old doorway is excellently painted, but the draperies of the woman and the child in the cradle are too bright in tone—they could not possibly be so light in such a dark building—the clothes too, hanging up, are crude and out of key. These inconsistencies spoil a work otherwise of much merit. The same artist sends another nicely painted interior, No. 390, "Tomb of the Princess Charlotte." A picture aiming at a higher ideal than do many pictures in the exhibition, yet showing some glaring faults, is No. 376, "The Cow Boy's Call," by Mrs. J. F. Herring. The sky and the cattle in the foreground are not in the same atmosphere, and the reflection in the water is wrong. It does not reflect the sky of the picture (which, by the way, though slightly exaggerated, is powerfully painted) but it reflects a totally opposite effect. The picture has evidently been worked at at two different times, for the cows are in rather a mellow evening light, while a heavy storm is lowering overhead. Still there is an effort in this picture which proves the artist capable of better things. In No. 382, "The Young Wife of a Royalist in troublous times," by Kate Aldham, the face is well painted and a nice expression realised. The dog in No. 390, "Guard it well," by Louise Swift, is well and broadly painted. No. 386, "Alan and Linda," children of Col. Mackinson, by Mrs. Charretie, are of course portraits. The faces are rather out of drawing, but the children are prettily posed and the accessories happily given. No. 424, "Carlino," by Miss E. S. Thompson, is solidly though rather flatly wrought. No. 394, "Found at last," by Alice Thornycroft, has been much laboured upon, but the figures are edgy, and have not the appearance of being painted at the same time with the background. The woman's figure is especially hard and cutting, and seems as if it had been done in-doors in a studio light; some parts, too, of the background are unnaturally forced; the child leaning over the water, is, however, very well painted and carefully finished. No. 430, "Morning on the Banks of the Medway," by Miss C. F. Williams, is decidedly the best landscape in the exhibition, painted with intention and vigour. The artist has chosen a grey and misty effect. The foreground of the picture reveals the sandy shore of an inlet, above which is a dark and watery sky, and a grey middle-distance rising into a narrow strip of brighter light, where the waters of the river touch the horizon. There is much merit in this work; but leaving now the oil pictures, let us turn to the water-colours, amongst which every variety of subject is to be seen; branches of flowers, babies' heads, snowdrops, dead birds, copies of pictures, studies in schools of art, sentimental country boys, plums, peaches, and cherries—some good, some bad, but, as a rule, indifferent. An exception to the rule, however, is No. 8, "Greenwich Hospital; News from the Crimea," by Louise Rayner, a work of great merit. The cleverly-coloured figures are well introduced, the dark blues of the old pensioners' coats contrasting well with the red stone and the red-grey bricks. No. 13, "A Girl at Crochet," by Mrs. Backhouse, is pretty, though very sketchily executed. No. 32, "The Thames at Goring," by Miss S. S. Warren, is a clever work, but the artist sees everything through a sort of brown haze, and her pictures are rather apt to be sleepy. Miss Warren's best drawing here is No. 211, "Sunset on the Kennet," which is very vigorously executed. No. 46, "A Boy Fishing," by Helen Thornycroft, has many good points about it. The boy is well drawn, though he seems inlaid into the background. There is merit in No. 63, "The Last Chapter," by Rebecca Coleman. The girl reading is carefully finished. Is not the head of the girl listening to her much too big? No. 99, "L'espoir de la fouille," by Madame Bisschop, is very clever in colour and excellently drawn; the light, too, is capitally concentrated. Miss Lane's "Study of Flowers," No. 131, though arranged in rather a higgledy-piggledy fashion, displays careful finish and conscientious work. The background of Miss Claxton's "Seven Hats," No. 132, is sadly out of perspective. No. 140, "Copse at Brenchley—early Spring," by Miss A. Morice, is very agreeable in colour; the primroses in the foreground are a little blurred, and would have been all the better for a few decisive touches of bright yellow to bring them into their proper place. No. 175, "Holiday-time at Hampstead Heath," by S. Wilkes, is good in colour and full of lively incident. No. 202, "On the Brathay, Westmoreland," by Mrs. Oliver, is well put together and the storm happily imagined. The body-colour is rather too freely used in No. 210, "Duck-pond, Eastbourne," by Marian Croft, but the choice of subject is good. On screen No. 1 are some excellent pen and ink sketches by E. V. B., all four entitled "Dreams." They are highly imaginative and exceedingly well drawn. This lady has greatly improved in her work, and displays much originality of thought. We commend her drawings to our readers' careful attention. No. 265, "Old Farm Buildings," by Miss F. M. Keys, is evidently the work of a beginner, but very good in colour. No. 285, "Wall-flowers," and No. 288, "Lauristinus and Rose," by Madame Hegg, are very cleverly executed. Miss Ward sends a nicely painted interior, No. 284, and Miss Sarah Linnell a most poetically wrought "Sunset," No. 314, very small as to size, but quite a gem of colour and very carefully wrought.

None of the copies in this exhibition appeared to us of even average merit, but there are three medallions in marble carefully executed; one a portrait of Carter Hall, by Mrs. Freeman, the other two profiles of children, by Miss Foley.

SELECTED DESIGN FOR THE LEEDS UNION INFIRMARY.

WE give illustrations of the ground plan and front elevation of the selected design for the Leeds Union Infirmary, sent in competition by Mr. Henry Walker, of Leeds. Special attention appears to have been bestowed by the architect on the matters of ventilation and heating. The design is to consist of four pavilions, with administrative blocks capable of accommodating 400 patients, yet so arranged that other blocks can be added when necessary. The erection of two pavilions only would meet all present wants. We shall give a perspective view of the building in an early number.

The design is Gothic in character, and will therefore harmonise with existing buildings on the estate. The sum per bed at the architect's disposal has forbidden the introduction of anything for mere architectural effect.

The structure is intended to be built in red brick, with sandstone dressings, the staircases and landings being of Bradford stone. The roofs would be constructed of Baltic red wood, and covered with Welsh slates: and the floors of the wards are intended to be carried on flitched beams, and laid in pitch pine, for polishing, if thought desirable. The walls and ceilings will probably also be finished with Keeno's cement, and brought to a polish. Throughout the building ordinary sash windows are shown. Smoke flues will be constructed of fire-clay tubes, now coming into general use, and all air-flues will be formed of common glazed earthenware drain tubes. Jenning's urinals, lavatories, and water-closets are recommended; and, for supplying the baths and sculleries with hot water, a Green's patent heating apparatus.

SUBJECTS FROM OLD MAJOLICA PAINTINGS.

IN this week's impression we lay before our readers a page of subjects from old majolica paintings, taken from examples preserved in the British Museum, South Kensington Museum, and the Louvre.

Majolica, as a species of ceramic manufacture, attained its perfection in the 16th century, then suffered the usual period of decay and oblivion, and is now, just after its revival, attracting the attention of the artistic nations of Europe. The name is supposed to be derived from the Island of Majorca, where the Arabians established some celebrated potteries. The introduction of majolica ware into Italy followed upon the taking of the Island by the Pisans in the early part of the 12th century. Its fame and importance soon spread over the whole of Italy, but it attained its greatest beauty and perfection in the cities of Urbino, Castel Durante, Pesaro, Gubbio, and Faenza. Giorgio Andreoli, a Pavian nobleman, who lived at Gubbio, was probably the best and most successful ceramist of any age or country; though he had worthy rivals, as majolica painters, in his son and fellow workman, Vincenzo, often called Maestro Cencio, Battista Franco, Orazio Fontana, and Raphael dal Colle.

The art at first depended almost entirely on richness and variety of colour, but in the second and best period this was superseded by design. The iridiscent glaze and colours were not neglected, but the highest value was attached to the execution of figure subjects. These were chiefly copies of the cartoons and sculptures of the old masters, especially of Raphael. It was at this time, about the middle of the 16th century, that majolica ware was so valued and so fashionable. Its manufacture was patronised by every Italian prince or Mæcenas, and its collection was the pet pastime of dilettanti and connoisseurs. Soon after, however, the fashion passed, and it was not until the last few years that we have seen it reappear, first in the shape of forgeries, and then of acknowledged imitations. It was long supposed

that Giorgio's method of workmanship was a secret lost to the world, but now the art is entirely recovered in every respect, and the London and Paris Exhibitions of 1862 and in 1867, specimens were exhibited by the principal countries of Europe. O. W. D.

COMPETITIONS.

BRADFORD.—The congregation worshipping in Sion Chapel, Bradford, propose to erect a new and capacious chapel and schools, on land extending from Harris-street to Peckover-street, Leeds-road, the site having cost £3,000. Designs for the new edifice have been prepared by Messrs. Andrews and Pepper and Messrs. Lockwood and Mawson, architects, Bradford. Both firms have chosen the Classical style. The former show an elevation to the Harris-street front, with towers boldly treated at each angle. The schools are placed in the rear of the chapel. Messrs. Lockwood and Mawson's design is in a more plain and subdued style. They dispense with towers altogether, the front of the building exhibiting a porch and pediment, the latter supported by four Corinthian columns, the treatment of the chapel being severely Classical, and plain and substantial in tone. They exhibit a tinted exterior and interior of the chapel. The schools are arranged on a somewhat different plan to that of their competitors, and the details are well attended to. The estimated cost of each is from £8,500 to £9,000.

ROCHESTER CASTLE AND GROUNDS.—Some time back we announced that the Corporation of Rochester had obtained a lease of Rochester castle and grounds from the Earl of Jersey, for the purpose of keeping the former in a state of preservation and of making the latter serve as a public recreation ground. Subscriptions were raised to lay out the grounds at an expense of £2,000 or more, and we now learn that no less than forty-eight sets of plans have been sent in by architects, landscape gardeners, and others, for laying out the grounds, &c. When this has been done, a great public improvement will have been secured for Rochester.

SHAFTESBURY.—Forty-two designs were sent in for the Cottage Hospital proposed to be built at Shaftesbury, Dorsetshire, as a memorial to the late Marquis of Westminster, K.G. After due consideration, the premium was awarded to the design bearing the motto "Perseverando," the author being Mr. J. B. Corby, S. Martin's, Stamford. At a committee meeting held on Wednesday last, it was ordered that the working drawings and specifications be at once prepared, and tenders obtained for the erection of the hospital.

LIMES AND CEMENTS.

LIEUT.-COL. SCOTT, R.E., delivered his second lecture on this subject before the Architectural Association on Monday evening last. After briefly passing in review the substance of the earlier portions of his previous lecture, he proceeded to speak again, and at some length, on the doctrine of chemical equivalents, a subject of very great importance in many matters with which the architect has to deal, and without a knowledge of which that part of his course of lectures which treated of testing limes and cements could not be well understood. He named the four points which it was essential should be borne in mind. First of all, chemical substances have always the same chemical composition; for instance, carbonate of lime always has the same proportion of carbonic acid and of lime wherever the specimen may be found, whether be (the lecturer) produced the substance chemically by uniting carbonic acid with lime, or whether it were formed by natural processes. Secondly, if one substance unites with another substance in more proportions than one, the second and the third proportions will always be multiples of the first, or bear some definite ratio to it. Thirdly, where we find a substance to combine with another substance, as hydrogen with oxygen to form water, and you determine what is the weight of the oxygen in the water, and then determine the proportion in which oxygen will combine with carbon and sulphur and other substances, you then know the proportion in which these bodies will unite among themselves. Fourthly, when we had ascertained the combining proportions of the simple substances in compounds, that then we should always find that the proportions in which they have combined will be according to the chemical equivalents of those substances. Referring to the combination of lime with water as an illustration, the lecturer exhibited some which had been obtained by the burning of Carrara marble, which was a very pure limestone indeed. Directly water was poured upon such lime a very violent action ensued, called slaking. In what proportion did water combine with lime, *i.e.*, how much water becomes solidified as a hydrate of lime in the dry powder obtained? This was readily shown by means of the chemical symbols CaO, HO, and the table of chemical equivalents on the wall. In every 37 parts of the hydrate of lime by weight there were 9 parts of water and 28 parts of lime, of which 28 parts of lime, again, 20 parts consisted of the metal calcium, and 8 parts of oxygen. If lime treated in this way with water were put into a bottle and shut up tight from the atmosphere after it had been made into a paste, there were no means whatever, as he had explained in the last lecture, whereby that lime could ever become a solid substance. But if the carbonic acid gas of the atmosphere got to it a change took place, the water being expelled by the carbonic acid gas. This gas, however, could never penetrate far into the interior of a heavy mass of mortar, and so the hardening process would be limited to a mere external film or coating. So far as the carbonic acid, however, did penetrate it would replace the water of the hydrate of lime to the extent of 22 parts by weight of carbonic acid for every 9 parts of water, carbonic acid, as the tables showed, being a compound of carbon and oxygen, in the proportion of 6 parts of carbon and twice eight, or 16 parts of oxygen. The lecturer then pointed out that the calcination of pure carbonate of lime was comparatively a simple operation; that pure lime, being infusible, there was little danger of over-burning, though, as it was possible for carbonate of lime to fuse in an atmosphere of carbonic acid gas, an excessive heat suddenly applied might, by fusing the outer crust of a large stone, prevent the escape of carbonic acid gas from the interior. Referring to the preparation of plaster of Paris, Lieut. Col. Scott said that if he burnt gypsum, which was represented by the formula CaO, SO_3, 2HO, to a temperature of 212 he should get rid of half the water it contained. If he carried it to 272° of heat he should drive off the whole of the water; in either of these cases the set of plaster of Paris could not take place; therefore, in the preparation of plaster of Paris from sulphate of lime these two extremes must be avoided, and an intermediate point be aimed at which left in the substance about half an equivalent of water or a quarter of the water contained in the gypsum. Artists, he remarked, preferred burning their own plaster of Paris. They did it very carefully. They ground it to a powder, put it into a sort of pan, which was carefully heated, and after a time it seemed to boil, and there was a tumultuous motion of the whole mass. This motion having ceased, the heating was stopped, as the compound had then arrived at the right point. Plaster of Paris was best burnt for building purposes on an extensive scale, in ovens resembling those used by bakers. The manufacturer knows when it is sufficiently burnt by its presenting a dull and earthy appearance in portions, with a few bright spangles or crystals here and there. The lecturer then again pointed out that plaster of Paris was a comparatively soluble substance, and was therefore quite unfitted for any work exposed to wet. Parian, Keene's, and Martin's cements all had a plaster basis, and though from the greater density which the heat to which they were subjected gave to them they could longer resist the action of wet, yet that they also would end by being dissolved by water. Coming to hydraulic cements and lime, the lecturer said that in this case we had carbonate of lime as it existed in nature, mixed with a certain portion of silicic acid. When these two substances were burnt together, the first action that took place was that the carbonic acid was expelled. The silicic acid at the high temperature became a strong acid, although by no means a strong acid at a low temperature; and if the heat were carried sufficiently far the lime and the silicic acid would form into a silicate of lime. The heat might, however, be carried to a to a certain intermediate stage, the nature of which was really very difficult to comprehend, but on which the action of hydraulic limes and cements depended. If he took silicic acid and mixed with it lime at the ordinary temperature, a certain weak action would be set up, as shown by the table on the wall, but very inferior to that which took place after the burning of the two together, as was done in the case of cements. In speaking of this the lecturer said he had assumed that the substances had a certain definite proportion to each other, viz., three equivalents of lime to one of silicic acid, an assumption which it was evident, from the varying nature of the beds of quarries, could rarely if ever be found in nature in any quantity in sedimentary strata. If he took out some of that lime and replaced it with iron, alumina, potash, or soda, and calcined the compound, he should then get a much more definite action between the silicic acid and the lime when mixed with water. The silicic acid, as previously stated, combined much more freely with several bases than with one base. With reference to the effect of different stages of calcination, if he were just to drive off the carbonic acid, and no more, the silicic acid and the lime would have no very strong tendency to combine with one another, but the lime would exhibit a very violent affinity for water. If the temperature were considerably increased the materials would fuse and lose the property of combining with water. If calcined to an intermediate point, they would, when mixed with water, run into a solid substance, like the set of Roman cement. Portland cement was prepared from an artificial mixture of carbonate of lime and clay, in which the proportion of iron, alumina, and other bases was not so large as in Roman cement stone, and would therefore bear a higher temperature than that stone without becoming inert in its action with water. It might indeed be said of Portland cement, when properly burnt, that it had been carried to a state of incipient infusion. It was then very dense, and for this reason its weight was a test of its quality, though not necessarily an infallible test, or even a necessary one in all cases. In many parts of the country—he mentioned the fact now lest it should escape his memory when he came to testing cements—"Portland" cement was made with Bath cement, darkened in colour by the admixture of a little lamp-black (laughter). It was very easy to detect this imposture, if suspected, without the test of weight. All that was necessary was to stir a little of it in a bucket of water, when all the lamp-black would come to the surface. Passing from the calcination of hydraulic cements to hydraulic limes, the lecturer stated the difference between the two to be this:—A cement is a substance which unites with water and slakes in one action. A lime slakes first and the silicic acid runs into combination with it subsequently. In burning hydraulic lime the main point should be to burn it "tender," as the workmen term it. There are often great difficulties in burning it, because the beds differ greatly in quality. Lias limes, of which there is great ignorance amongst builders, are often better in quality in the bag than in the lump, the lump lime being made from the harder stones containing a less proportion of clay than the beds used for ground lime. Ground lias lime, supposing it to be well burned and ground, is, therefore, as a rule, better than the lump lias which comes into the market. After stating the various proportions of fuel necessary for burning various descriptions of limes, the lecturer proceeded to speak of the slaking of limes. With reference to fat or pure limes he observed that it was unnecessary to grind them, because directly water was put to them they slaked to a finer powder than they could possibly be reduced to by mechanical means. Cement and plaster of Paris of course must be ground; add water to a lump of either in its unground state, and it would still remain a lump, merely becoming harder from the solidification of the water. With regard to hydraulic lime, it might or might not be ground before using; but the wisest plan was always to grind it, for however carefully the lime might be burnt it was impossible to avoid the over-burning of some particles which might subsequently slake in the work or occasion its disruption. As to the practical question of the best way of slaking limes there were great discrepancies of opinion. Vicat had written upon the subject, as well as Treussart, Raucourt, Pasley, and others. They described three modes in which the slaking could be conducted. Firstly, what they termed the ordinary mode, which is identical with that practised all over London at the present time. In this mode the lime was surrounded by sand and enough water was thrown upon it to bring it to a fluid paste, which was subsequently more or less imperfectly incorpo-

rated with the sand. The second method, that of immersion, consisted in dipping the lumps of lime, placed in baskets, in water until the hissing ceased, and then throwing them into a heap to finish slaking. The third method of slaking lime was by the spontaneous action of the atmosphere on the lumps, when spread out and exposed for a length of time. Vicat put the relative merits of these different modes in the following order:—

Fat Limes.	*Hydraulic Limes.*
Ordinary.	Ordinary.
Spontaneous.	Immersion.
Immersion.	Spontaneous.

Rancourt considered the following to be the order:—

Fat and feebly hydraulic.	*Hydraulic and Eminently hydraulic.*
Spontaneous.	Ordinary.
Immersion.	Spontaneous.
Ordinary.	Immersion.

The lecturer suggested that when such discrepancies existed, General Pasley was not far wrong in placing no reliance on Vicat's nice distinctions. The lecturer believed the best plan of slaking strong hydraulic limes to be that of sprinkling them well with water, and then covering them up with sand for twenty-four or forty-eight hours to keep in the steam, and thoroughly slake the more inert particles. This was also the method recommended by Treussart. In conclusion, the lecturer compared some experiments made by General Treussart and Mr. Cahill, Clerk of the Works of the War Department at Plymouth. From the latter it appeared that

Plymouth lime, 70lb. to the bushel, required to bring it to a paste six gallons of water, and made 2¼ volumes of paste.

Keynsham lime, 80lb. to the bushel, required to bring it to a paste three gallons of water, and made 2¾ volumes of paste.

Lyme Regis lime, 70lb. to the bushel, required to bring it to a paste two gallons of water, and made 1 6-7th volumes of paste,

whereas the bulk of paste of lime obtained by General Treussart from limes of similar chemical composition was far smaller. The lecturer believed these discrepancies to arise from the different modes of conducting the experiments.

ANNUAL INTERNATIONAL EXHIBITIONS.

WE are requested to publish the following:—Her Majesty's Commissioners have reason to believe that sufficient attention has not been given by architects to the fact that in the approaching Exhibition a gallery will be specially set apart for architectural designs, in which drawings contributed from this country will hang side by side with those of continental artists.

It appears highly desirable, considering the great publicity which the Exhibition will have, and the comparisons which will be instituted between English and continental contributions, that the works and the studies of English architects should be represented in a thoroughly satisfactory manner.

It depends upon the public spirit of individual architects and artists to ensure that this opportunity, the first of its kind, but which may be made the foundation of an annual Exhibition of a very satisfactory description, is not thrown away.

Facilities exist in the way of exhibitors, owing to the rule excluding works previously exhibited being relaxed this year; so that drawings suitable for exhibition, but which have been already exhibited at the Academy or elsewhere, may be sent in.

Owing to the intention of Her Majesty to open the Royal Albert Hall, in which the Architectural Exhibition will be held, on the 29th March, Her Majesty's Commissioners desire to extend the time for the reception of architectural works until Friday, March 31st, when all objects must be delivered at the Royal Albert Hall, Kensington Gore, into the charge of the proper officers, unpacked and ready for immediate exhibition, and free of all charge for carriage.

It is desirable that a previous application for space should be made; but when it has been impossible to comply with this formality, objects may still be sent in for exhibition, and will be admissible if there be room for them.

The works sent in by architects for the Exhibition of 1871 will be submitted for approval to a Committee for Selection, consisting of the following members:—Lord Elcho, Lord Bury, Sir Coutts Lindsay, Mr. E. M. Barry, R.A., Mr. Joseph Clarke, F.S.A., Professor Hayter Lewis, Mr. T. Roger Smith, Mr. Alfred Waterhouse.

ON LONDON AS A FIELD FOR ARCHITECTURAL STUDY.*

(*Concluded from page* 115.)

THE introduction of terra-cotta as a material for the decorative features of buildings has directed attention to the examples in North Italy, where this material was originally employed. At South Kensington a great deal of building is, as you may know, going on, and the red brick and terra-cotta treatment adopted there (which I suppose we must consider due to the late Captain Fowke and Mr. Godfrey Sykes) is well deserving attention. The merit of the detail is very unequal, but some parts of the buildings for the Museum itself, of that for the schools, and of the Albert Hall, are very fine specimens of artistic treatment of a material not hitherto sufficiently employed. Near South Kensington Lady Marion Alford's house, now in progress, may be mentioned as a good example of the same class of work.

All this time I think one section of my hearers must have considered that I was forgetting them, and straying very far away from "true principles." I am coming to Gothic at last, but I must ask my friends of the Gothic school to remember that London, whatever it was before 1666, is not now a Gothic city, and never will be again. The old Mediæval work is, as we have seen, scanty, though good. The new is but scanty also, and does not seem to me much on the increase. It is true that since the Gothic revival few churches have been built in or round London in any other style, and many Gothic schools and some parsonages have been built, but here the list halts. We have one Gothic club, one railway station and hotel (not completed yet). We had at least two good Gothic warehouses, but have pulled one of them down; we have four or five sets of offices, no theatre, one bank (since abandoned), and perhaps two or three mansions. This (unless the Houses of Parliament may be supposed to make up for shortcomings elsewhere), is a sorry sort of list to compare with the hundreds of buildings that might be quoted in other styles; and that fact alone ought to induce architects who intend to practise in London to beware how they make themselves exclusively Gothic students, unless they are willing to content themselves with church architecture alone. I suppose, however, that I must be content to admit that many of you are so circumstanced that the study of Gothic architecture is the one forced on your attention by your surroundings, and probably selected by you as your favourite pursuit. Do not make it your exclusive one, or, at any rate, not through your whole career; and if you are fixed in London, try and remember that here you really have, as I have shown, very considerable special facilities for learning Italian Renaissance architecture, both from Wren's works and from the best recent examples, while (except your office practice, the Abbey, and Museums) you have few special advantages as regards Gothic. Among the many modern London churches of Pointed architecture there are some which were built before the revived style was fairly understood, such, for example, as Barry's earliest churches. These you must put aside. They were followed by a series of examples which are reproductions pure and simple of English churches, correct in detail and in mass, and many of them full of beauty. More recently churches have been built, and are building now, showing more originality and often great ability, but their authors are often found culling details from various sources and mixing them, with a noble disregard of absolute consistency, and seasoning the whole with entirely novel and original forms and enrichments. Now I very strongly advocate the early study of the second group of churches, as likely to be the most serviceable in the first instance. There are, I believe, churches in London which are as good examples for the purposes of study as if they had been built in the Middle Ages, but they are not the most popular churches; and of the latest built ones I believe that some, while we cannot refuse to admire them, are a little dangerous in the influence they might exert. Of Pugin's work we have, I think, only the Roman Catholic Cathedral of S. George's Southwark, by no means one of his best productions; but you may rely upon its features as accurate. His secular work at Westminster I will refer to later. Of churches by his successors I may name Mr. Pearson's earlier works, such as his excellent church at the Middlesex end of Vauxhall Bridge. Mr. Raphael Brandon's fine Irvingite Cathedral in Gordon-square, some of Mr. Ferrey's churches, and perhaps S. Barnabas, Pimlico, as samples of a large class, which I believe might be very serviceable as a groundwork for the study of Gothic. Of the immense mass of Protestant Nonconformist places of worship in the Metropolis, though many are good specimens of economy and ingenuity, I think those by Mr. Emmett the ones that it occurs to me I might best class with this series. But, on the other hand, you can hardly go wrong in reckoning in any recent Roman Catholic church that is Gothic at all. This subject is so familiarly known to many here that I make no apologies for treating it with much more brevity than suits its great importance, and pass at once to recent churches, with detail drawn from Continental originals. The introduction of French and of Italian Gothic detail seems, if it has enlarged our means of producing effect and added largely to our resources, to have rendered some of our best churches to a certain extent inconsistent. Some there are which might be taken as good examples of French throughout, and these are the best; but there are others where French, Italian, and English features mix together. With a caution on this head, the whole of the churches of Mr. Street, Mr. Scott, Mr. Burges, Mr. Butterfield, and Mr. Goldie that are accessible are to be warmly commended to the student, as well as many more which I cannot here enumerate. It may be worth remark, before we leave the question of churches, how very few modern London Gothic churches are *town* churches, as many of Wren's are—that is to say, built close to a street, embedded among buildings, and devoid of a churchyard. Mr. Butterfield's fine church and dependent buildings in Margaret-street may be taken as a masterly example of the mode of procedure which suits such circumstances. This I name principally because it accounts a good deal for the likeness of many modern London churches to good country churches, and leaves a good deal to be worked out by the architect who has a very restricted town-site to build upon. Parsonages and schools are frequently to be found associated with the churches of London, and in the main will be found in the matter of architectural consistency to correspond with the buildings from which they are dependent. A good deal of good domestic architecture may thus be found scattered about among these buildings, which form a kind of link between secular and ecclesiastical architecture.

Among our moderate collection of Gothic secular buildings, the first place is, I think, due to a small unpretending and now unoccupied house in Bridge-street, Blackfriars, where the genius of the late Mr. Woodward has shown what an artist—a real artist—can make of so simple and commonplace an object as an ordinarly London house-front, with its two windows and a door for the ground floor and three windows above. This building, admirably adapted to London arrangements, and plate glass, and the Building Act, and everything else that we think totally inconsistent with fine art or Gothic, is the most artistic bit of its size that I know, and deserves that it should be drawn, every stone of it, by a dozen of you. Its general lines have been preserved, but not its spirit, in a larger building erected in Fleet-street for the same company which originally occupied it, and you may draw from this a hint as to the extreme difficulty of re-producing a design, and the value, among other things, of material as an element in design. Part of the great excellence of Mr. Woodward's building is due to the fact that, being in granite, it is treated in every way suitably to the qualities of the material. Part is also due to its excellent proportions, which are not of course preserved by retaining its features in a building put up upon a different-shaped site, with more frontage. There exists in Thames-street an admirable Gothic warehouse by Mr. Burges—a narrow slip of frontage, such as many of you will have to deal with in your day, but sufficient to display the hand of a true artist; and this I recommend to your careful notice, adding the hint that part of the instructions were not to furnish any extensive light in the façade, as an explanation of the small amount of window-space it shows. I wish I could also send you to Mr. Somers Clarke's excellent warehouse in Smithfield, but the City bought it and pulled it down for the new meat market, and it exists only in drawings. We have, however, by the same accomplished architect a good specimen of Venetian Gothic at the corner of Tokenhouse-yard, which I think you may safely accept as a thoroughly trustworthy example. We have three excellent Gothic monuments. The first is the restoration of the Cross of Charing, in front of the South-Eastern Railway Terminus, by Mr. Edward Barry. I believe this to be as faithful as it is beautiful. I know that no pains were spared to make it so, and any student in search of instruction may accept it as a trustworthy example. Next I would direct your attention to Mr. Scott's Crimean Memorial at the west front of Westminster Abbey. If it had but a larger base, this would, I think, be improved; but it is, even without that, a most elegant and vigorous design, admirably carried out. Lastly, there is the Albert Memorial, which I am not going to analyse or criticise before you to-day. Nothing is more unfair to a great artist like Mr. Scott than to form or express a decided judgment upon the general effect of his work when incomplete. But details and features have a completeness of their own, and the details of this work are full of beauties. I recommend you to watch it narrowly, to examine

* Read before the Architectural Association on Friday, the 27th ult., by Mr. T. ROGER SMITH.

it very carefully from time to time, and, when it is thrown open, to give most careful attention to it as the most remarkable work of its class in the Metropolis. Another work by the same eminent architect is the S. Pancras Terminus. Here the work is still unfinished, but so far advanced that one may, with greater fairness, presume to judge of its completed state. I think you ought to examine it very carefully and constantly, as a very good example of the best domestic Gothic of the present day, and as a good specimen of what one may call a stone building with the walling translated into brick. Another large and good example of Gothic is to be found in Lincoln's Inn Hall andLibrary, built early in the days of the Gothic revival, and yet with extremely little about it that one could wish to see altered, or wish you to abstain from becoming familiar with. Near here standtwo modern Gothic buildings which require notice. In Endell-street Mr. E. M. Barry has built a very fine block of schoolbuildings, in red brick, of a Lombardic Gothic character, which are worth your attention, not, perhaps, so much for detail as for vigour of general design, while close to them, in a short street on the east side of Endell-street, stands a school by that able architect Mr. Wild, which, as a specimen of the effective treatment of a brick arcade, is to my mind almost unsurpassed. I am now going to pass on to the last example I shall have to quote of these Gothic secular works, and before doing so wish to say a word as to my *omissions*, which will, I trust, be largely made up by members present during the discussion. Many buildings, undoubtedly, which you might have expected me to notice, have been designedly omitted because I purposely intended those which I named to be merely specimens, and not, in any sense, to give complete lists. Some architects also whose works I should very earnestly recommend to you, are left unnoticed because they have either built nothing in London, or the London examples of their work are, in my opinion, not up to the level of their general work. Some architects, and an enormous number of buildings, are, however, left out, because it is no part of my intention to furnish you to-night with an *index expurgatorius* of what to avoid in London. A very little knowledge will teach you how to shun the worst types; but there are many buildings about which a taste cultivated by travel or the judicious criticism of a good judge is needed, in order to tell you if they are good or not, and all I can say to you about them is—take the best advice you can get. To resume, and conclude, the last Gothic example I shall name is the Palace of Westminster. Some Gothic architects will say, or used to say some years ago, that it is not Gothic, and I quite admit that the general design of the building is not arranged on the principle (generally adopted by the Gothic architects) of displaying outside the shapes and arrangement of the inside, Barry has put behind a symmetrical façade a House of Lords on one side and a House of Commons on the other, and shown neither of them; just as a symmetrical human trunk contains a heart and a liver placed symmetrically and shows neither of them. Westminster is really one of the finest Gothic buildings of Europe, and its endless sculptures, metal-work, decorations, stained glass, and carved wood-work, are a magazine of wealth; just as its roofs, pinnacles, and towers are rich studies of mass and form I regret the style chosen for it, but notwithstanding that, and one or two other drawbacks, it contains the best work of Sir Charles Barry, Pugin, Thomas, and a host of others, and it is a fine—alas! almost our solitary—example of a great building consistently carried out, furnished, and decorated. It is a building that would exercise a good influence on the mind of any one who would often visit it, and it is a thing for a London architect to be proud of. I have now filled up a great deal of time, and have not approached the obvious part of my subject—the one which I have no doubt some may have expected would take the whole evening, and to which I will confess I had originally intended to give some prominence. I refer to London works at the present day; but I really feel that these almost force themselves on your notice, while some of the things I have enumerated might have escaped you. The fact that London offers immense buildings and improvements of all kinds for you to watch is so self-evident that you cannot need telling; but it may be worth while noticing that for some of these things London is a good, for others, a bad field. I believe that in very large structures for public purposes, London is rich. The Agricultural Hall, eight or nine railway termini, the British Museum Reading-Room, the Albert Hall, the Alexandra Palace, and the Crystal Palace, form an *ensemble* that for bigness cannot soon be excelled. In public institutions we are rich. Hotels, hospitals, infirmaries, workhouses, sick asylums, institutions, could be better studied here than anywhere in England—perhaps better than in any European city. In colleges, libraries, museums, we are not high; in royal palaces we are at zero; in Law Courts we are below zero. In warehouses and factories we are poor, except printers' and publishers' places, some of which are good; but if any of you want to study the best examples of those buildings let him go to Lancashire and Yorkshire, and see the mill's and warehouses of Bradford, Halifax, and Manchester. In shops and street fronts we are poorer still. I hardly know one good shop front in London, except Sir Digby Wyatt's print shop in Grace-church-street. In drinking fountains and public statues we are at a low ebb. In dwelling-houses we are disgraceful as to construction, bad as to design, but good as to arrangement; and the *plans* of common builders' houses will give you many a wrinkle if you look out sharp. In bridges, I think we are good. In streets, we used to be very indifferent, though at last London is beginning to learn very slowly the art of laying out streets liberally and the value of height. The Thames Embankment and the works connected with the Holborn Viaduct are the first improvements for some time past in which large-handedness has been traceable, and there is nothing more painful to a stranger who has returned home from the Continent than to compare the spacious boulevards and large open places he has left with our narrow thoroughfares and the mean spaces in front of our railway stations, unless it be to contrast our low buildings of two and three stories with the lofty structures by the help of which our more thrifty Continental neighbours economise space and expense. Here we are slowly learning better, and in Victoria-street and on the Grosvenor estate buildings can be found better suited to go with a wide street, and to supply the wants of a large city than our usual houses. The value of works in progress has been often impressed upon us by those excellent visits to them which occupy Saturday afternoons in the summer time, and I shall say nothing about them. Might it not be a good thing, if not for the whole Association, at least for the members of the Junior Class of Design, to visit some of those buildings not in progress, but in use, which may be looked upon as good typical examples for study? I throw out this hint for the consideration of the committee, and I can only say that if it were adopted I should willingly do my best to assist such a party of students in examining any building with the style or peculiarities of which I am familiar. This, or some such expedient, might help us as an Association to get good out of London; but I should like, in concluding, to urge strongly upon individuals the paradox that he will get most good here who goes oftenest away. There is so much bad architecture and bad building, and so much of what has been not inaptly termed the vernacular—or builders' compo style—that the best taste gets vitiated, the keenest perception grows blunt; and the most observant criticism becomes dulled. To me London never seems so full of good architectural points as when I return from a visit to some well-built city of the Continent, and never so poor and dull (except the picturesque beauty of the River Thames, of which I think no one with the least fragment of a painter's eye could ever tire) than when I have been continuously here for many months. Regard London, then, as a dangerous place—a place unsuited to the formation of your tastes and ill fitted to be your sole studying ground, but yet rich in buildings and objects which we can make very useful to us if we will.

ART WORKMANSHIP PRIZES.

PRIZES have been awarded to the contributors of the following articles sent in competition:—

CARVING IN WOOD.

3. Oak Panel; design adapted from an old panel; by J. Osmond, 5, Featherstone-street, Bunhill-row, E.C. Price £18. Prize of £5

5. Mirror-frame, carved in oak and ebony; by W. H. Holmes, 117, Dean-street, Soho, W. The mirror by W. Evans. Price £7 10s. Prize of £3, to W. H. Holmes.

10. Carving from Nature, lime-wood; by R. J. Tudsbury, Edwinstowe, Notts. Prize of £10.

INLAY IN WOOD.

12. Amboyna Inlaid Loo-Table, the lower part inclosed by four marqueterie panels (fixed); designed and executed by Thomas Jacob, 4, Upper Charlton-street, Fitzroy-square, W. [The Society's silver medal and prize of £25; also the North London Exhibition prize*], assisted by Cornelius Riech (marqueterie cutter) [prize of £12], Charles Helfer (engraver) [prize of £5], George Brown (turner) [prize of £1], Joseph Platt (carver) [prize of £1], and George Tappin (polisher) [prize of £1]. Price 100 guineas.

14. Cabinet in mahogany and ebony woods, metal gilt mouldings (plaques painted on ivory); exhibited by W. Bertram & Son, 100, Dean-street, Soho, W.; designed by W. M. Holmes; carving by W. M. Holmes and W. Maskell; cabinet work by C. Peterson and J. Hickman. Prize of £5 each to W. M. Holmes and W. Maskell.

INLAY IN MARBLE.

15. Table-top; by J. Taylor, 6, Mead's-row, Westminster-bridge-road, Lambeth, S.E. Price £16. Prize of £3 for this and No. 16.

16. Group of Flowers; by the above. £25.

CARVING IN STONE.

18. Group of Flowers; by J. Goudge, 117, Page-street, Westminster, S.W. Prize of £2 for this and No. 19.

19. Bird and Foliage; by the above.

* This prize consists of £4 18s., the interest of £167 7s. 9d. Consols, invested in the name of the Society of Arts, to be awarded by the Council "for the best specimen of skilful workmanship" at the Society's Exhibition of Art-Workmanship.

MODELLING IN PLASTER.

20. Figure of a Child; by J. W. Gould, 85, Castle-road, Kentish-town, N.W. The Society's silver medal and a prize of £10.

22. Portion of a Frieze for Drawing-room, Thoresby-hall; designed and modelled by J. Daymond, jun. (under Mr. A. Salvin, architect), 4, Edward-street, Vincent-square, S.W. The Society's silver medal and a prize of £10 for this and Nos. 23 and 24.

23. Alternate Centres for Frieze of Dining-room, as above.

24. Portion of Frieze for ditto, as above.

METAL WORK.

Church Plate, exhibited by Messrs. Cox & Son, 28 and 29, Southampton-street, Strand. Executed under the superintendence of Mr. John Keith.

Messrs. Cox & Son, Mr. John Keith, and Mr. B. J. Talbert have each been awarded the Society's silver medal. A prize of £5 is awarded to H. Tickell, in respect of Sets Nos. 2 and 4, and a prize of £3 to J. Keith, jun., in respect of Set No. 3.

39. Watch-case and dial in silver; by T. J. Bowman, 2, Rheidol-terrace, St. Peter's, Islington, N. Price £5. Prize of £1.

41. Card-tray; designed by W. U., chased by P. A. Price, £2 2s. Prize of £1 each to designer and chaser.

48. Damascened steel-bladed trowel; designed by Sebastian G. Rice, executed (with the exception of the ivory handle) by T. R. Rice, Messrs. Hart, Son, & Co., Wych-street, W.C. Prize of £5 to T. R. Rice.

50. One of a pair of wrought-iron gates; executed for the Union Bank of London, by T. Winstanley, 25, New Compton-street, W.C., assisted by G. Winstanley and F. Lancester, apprentices; designed by Mr. Porter, architect. Messrs. Porter and T. Winstanley have each been awarded the Society's silver medal. Prize of £10 each to G. Winstanley and F. Lancester.

51. Hammered bracket in iron; designed and produced by W. Morris, 14, Goding-street, Vauxhall, S.E. Price £5. Prize of £3.

52. Hammered bracket in iron; designed and executed by William Robson, 11, Parkside-street, Battersea-road, S.W. Price £3. Prize of £2.

53. Gas Standard in brass; designed and executed by Joseph Taylor, 12, Wynford-street, Islington, N. Price £12. Prize of £5 for this and No. 54.

54. Inkstand in brass; designed and executed by the above. Price £6.

56. Portrait in repoussé, from a carving by Jean Goujon; by Robert Tow, 36, Aldenham-street, St. Pancras-road, N.W. Prize of £7 10s.

57. Head of Satyr, repoussé in copper; blocked by W. Theuerkauff, and chased by G. Deere, 11, Hermes-street, Pentonville, N. Prize of £4 to W. Theuerkauff and £3 to G. Deere.

59. Tobacco-jar and cover (Elizabethan period); designed and executed by F. B., 31, Cantelows-road, Camden-square, N.W. Prize of £1.

CAMEO CUTTING.

63. "Psyche;" designed and cut by J. Ronca, 42, Blantyre-street, Chelsea, S.W. Prize of £2 for this and Nos. 64 and 65.

64. "Clytie;" by the above.

CARVING IN IVORY.

65. "The Rainbow;" by J. Ronca, 42, Blantyre-street, Chelsea, S.W.

GLASS-BLOWING.

69. Two plain Toilettes; by Elijah Barnes, 13, Hingeston-street Birmingham. Prize of £5 for this and Nos. 70-72.

70. One ditto, with twisted stand; by the above.

72. Flower-glass; by the above.

73. Two toilettes, with filigree; by T. C. Barnes, 135, Camden-street, Birmingham. Prize of £7 10s. for this and Nos. 74-75.

74. Flower-glass in green and splashed with gold; by the above.

75. Loving-cup, by the above.

The following are exhibited by Messrs. Cox & Son, 28 and 29, Southampton-street, Strand, W.C.

6. Polished brass eagle lectern (jewelled); designed by B. J. Talbert; brass worker, J. Skelley; chaser and modeller, A. Barrett; engraver, James Keith. Price 120 guineas. Prize of £3 to J. Skelley, for this and other specimens.

78. Wrought-iron gas standard, relieved with brass and jewelled; designed by B. J. Talbert; forger, W. Prendergast; fitters, R. Emms (lower half of standard), and J. Morgan (upper half of standard, including bumping leaves). Price 36 guineas. Prize of £3 to W. Prendergast.

79. Board with specimens of chasing and modelling; two fire-iron heads, figure of "Hamlet," A Barrett; three studies from natural foliage, G. B. Tapley; two classic dishes, E. Richards; hinge for side and front of sideboard, R. Emms. Prize of £1 to G. B. Tapley, and of £2 to E. Richards.

81. Caen-stone font, with marble columns and bosses, and oak cover with wrought-brass mountings and chain; designed by B. J. Talbert; mason, T. Woodcock; stone carvers, C. Abbey and R. Davis; joiner, E. Hooper wood carver, T. Burdett; brass workers, J. Skelley and W. Marsden; beaten cross chased by A. Barrett; engravers, W. Lucas (two upper bands and leaves) and J. Taylor (lower band and leaves). Price, font 60 guineas, cover 100 guineas. Prize of £2 to W. Marsden.

82. Reredos and altar-table, with frontal, the panels in hand-painted encaustic tiles; subject, "The Last Supper;" designed by B. J. Talbert; cartoon of subject, M. Casolani; masons, T. Woodcock, T. Brock, and R. Sutton; stone carvers, C. Abbey and R. Davis; tile-painter, W. W. Robinson; joiner, W. Layfield; wood carver, W. E Matthews; embroideresses, Fanny Thurling and Susannah Grice. Price 100 guineas. Prize of £2 10s. to M. Casolani. £2 10s. to W. W. Robinson, and £1 10s. each to Fanny Thurling and Susannah Grice.

Probably the largest amount of personalty ever transmitted by one person is the personal estate of the late Mr. Brassey, the railway contractor, whose will has just been proved in the Court of Probate. His personalty alone is reported to have amounted to six and a half millions.

PARLIAMENTARY NOTES.

PATENTS FOR INVENTIONS.—Mr. Samuelson gave notice in the House of Commons, on Thursday week, that on the 13th of March he should move for a Select Committee to inquire into the law respecting the grant of letters patents for inventions.—Mr. H. Palmer gave notice for the 1st of March of a Bill to amend the law relating to patents for inventions; and Mr. Macfie gave notice to move on Tuesday the 14th inst., for a Select Committee on the same subject.

PUBLIC PARKS AND MUSEUMS.—Sir W. Hutt gave notice that on an early day he should move the introduction of a Bill for facilitating gifts of land for public parks and museums.

THE NEW COURTS OF JUSTICE. — Mr. G. Gregory, on Friday, asked the cause of the delay in commencing the building of the New Courts of Justice.—Mr. Ayrton was not surprised at the question, considering the interest the honourable gentleman had taken in the subject, and the persistent statements during the recess of his (Mr. Ayrton's) dislike to the scheme for building the Courts of Justice on the site now selected, and that he had done his best to prevent the commencement of the work. The project for the erection of the buildings was submitted by the member for Richmond about five years ago to the House, and that project was that Government should purchase a site at a cost of three-quarters of a million of money, and should erect upon it courts of justice which were to cost the same sum. Commissioners were appointed to give their sanction to the details of the project, and to guarantee to the House that the expenditure on the whole should not exceed £1,500,000 sterling. When the plan was brought forward he gave it his earnest support, and urged the House to carry it into effect at the earliest possible period; but the Commission, instead of conforming to those conditions, adopted a scheme which was to cost £3,250,000. That project had been to some extent matured when her Majesty's present Government took office, but in consequence of discussion that arose, nothing was done for a year, and it was not till the Christmas before last that he was requested to take steps to induce the Commissioners and all others concerned to adopt some plan which would give effect to the intentions of Parliament in passing the Act. It would have been almost easier to have begun again than to have reduced the scheme which had reached £3,250,000 of estimated outlay down to the original dimensions of £1,500,000, and in the meantime the expenses on account of land purchases had increased to £900,000. After going into all the details, they were enabled to bring the project within the original compass; but still difficulties arose in reference to the construction, which were so serious, that as early as March last he suggested to the architect that he must radically change his plan if he was to conform to the wishes of Parliament. The architect exercised all his ingenuity to carry out his design, but in July he came to the conclusion that it would be better to take the course which he (Mr. Ayrton) had suggested months before. In August last the Commissioners brought forward a report approving of the plan, and it was sent to him from the Treasury, with the request that he would take the necessary steps to carry it into effect. It was not till the end of September that a formal contract was made with the architect, clearly defining his duties, and his relations with the Office of Works; and directions were immediately given to prepare a sketch plan. The architect stated that it was impossible to do that before the 1st of January, and that working plans could not be prepared before the 1st of July. In order that no delay should take place in proceeding with the work, he (Mr. Ayrton) requested the architect to prepare immediately specifications, in order to lay in the foundations, and to get the ground ready for the superstructure. At the end of November, while the sketch plan was in progress, the specifications were sent in, and tenders for the work were at once invited. It required some time for builders to ascertain what they were to tender to do, but as soon as they were aware of the nature and extent of the work they protested against the shortness of time allowed them for the completion. In consequence, the time was extended from the 1st of September to the 1st of February, when the foundations would be completed. He did not think this would lead to any delay in the erection of the buildings, because in the meantime all the working drawings and preliminary steps for the superstructure would be going on. The contractors were to go on *pari passu* with the preparation of the working plans and drawings, so that as soon as possible they should be in a position to tender for the whole work. So desirous were the Government to have this work carried out properly and promptly that notice had been given for the purchase of additional land that would be required. The result would be that, apart from the additional expense in the purchase of land which could not be avoided, the building would ultimately be erected for the original sum proposed—namely, £750,000, and it would be better and more useful for the public service in every respect than it would have been if the vast expenditure which had been checked had been incurred.

MUSEUM OF PATENTS.—Mr. H. Palmer, on Monday, asked the First Commissioner of Works whether any steps had been taken, or were intended to be taken, for providing a patent museum and offices adequate to the requirements of the nation, in pursuance of the report for 1869 of the Patent Law Commissioners and the several previous reports therein referred to. Mr. Ayrton said great diversity of opinion prevailed upon the subject, there being three different suggestions made in three parts of the report. During the last few years the patent laws were very much called in question, and two hon. members had given notice of motion for the appointment of a select committee to inquire into them, with a view to their entire abolition. Under these circumstances it was hardly expedient to embark in any large expenditure, such as that which would be entailed by the construction of a museum of the proportions desired by some persons.

THE ROYAL SANITARY COMMISSION.—Sir C. Adderley asked the Secretary of State for the Home Department whether he intended to introduce this session a bill for consolidating in one all the sanitary Acts, and giving better means of local government to every place in England and Wales outside the metropolis, under a central department, as recommended, and to a great extent prepared in the report of the Royal Sanitary commission.—Mr. Bruce, before answering the question, said he was anxious, on the part of the Government, to thank the right hon. baronet and the other Royal Commissioners for the great care and labour they had bestowed on this important inquiry (hear, hear), and the special pains they had taken to facilitate legislation in respect to it by the careful analysis they had made of the complicated laws on the subject. Through the right hon. baronet's courtesy he received a draft of the report before it was presented to Parliament, but at a late period of the recess, when every department was busily occupied in making arrangements for the approaching session. Several of the departments, however, connected with the administration of the sanitary laws were giving their close attention to the subject, and if the right hon. gentleman would wait for about three weeks he would find that the labours of the Royal Commission had not been in vain.

THE LAND TENURE.—Mr. C. W. Hoskyns, on Tuesday, gave notice that he would on the 14th March call the attention of the House to the injurious effects of the existing system of entail, as diminishing the investment of capital on the soil and obstructing the freedom of the land market, and would move a resolution.

EUSTON, ST. PANCRAS, AND CHARING-CROSS RAILWAY.—Mr. Crawford gave notice that he would oppose the second reading of this Bill if certain plans were not deposited.

INCLOSURE LAW AMENDMENT. — Mr. Shaw Lefevre moved for leave to bring in a Bill to amend the law relating to inclosure of commons, and to provide for the management of commons situate near towns. The main object of the Bill was to provide that in all cases of inclosure of rural commons, one-tenth of the land inclosed should be applied to the formation of public recreation grounds, or to allotments for the poor, provided that the quantity of land so appropriated should in no case exceed 50 acres. It also prohibits all inclosures within five miles of considerable towns, except under the direction and control of the municipal authorities. In the case of rural commons existing facilities for inclosures would not be interfered with, except in so far as related to the reservations which he had stated. —Mr. Fawcett expressed a qualified approval of the Bill, as showing an intention on the part of the Government to bring the question of the inclosure of commons fairly before Parliament.—Mr. Macfie warmly supported the Bill.—Mr. Whitwerth hoped that care was taken in the Bill for the preservation of accustomed footpaths.—Mr. Lefevre replied, and leave was given to bring in the Bill.

METROPOLITAN WATER SUPPLY.—Mr. Shaw Lefevre gave notice, on Wednesday, that he would on Thursday move, in Committee of the whole House, that the Chairman have leave to bring in a Bill to amend the Metropolitan Water Act, with a view of securing a better supply of water to the Metropolis.

Building Intelligence.

CHURCHES AND CHAPELS.

BLACKBURN.—The Baptist Chapel, Montague-street, was reopened on Wednesday last, after having undergone a thorough renovation from the effects of dry rot, &c. A new floor and gallery with open benches has been substituted, which now provides 600 sittings, being double the number it formerly held. The whole is carried out in pitch pine of a superior quality, and varnished, from the designs and under the superintendence of Mr. James Bertwistle, architect, Blackburn.

NEW WESLEYAN CHAPEL, BURNLEY. — The foundation stone of a new Wesleyan chapel was laid at Burnley on the 4th instant. The style will be Lombardic. Seats are provided for about 700 persons, and the cost will be about £2,440. The architect is Mr. Wm. Waddington, of Burnley.

WOLSTANTON.—A new school-church at Longbridge Hays, near Wolstanton, was opened on Thursday week. The cost of the school-church has been about £550. The building will seat 180 worshippers, and accommodate 125 children for educational purposes, being 42ft. by 20ft., with a class-room 16ft. by 14ft. Mr. Lewis, of Newcastle, was the architect, and Messrs. Bennett & Cooke, of Burslem, have satisfactorily completed the building.

BUILDINGS.

HENLEY UNION.—We understand that new buildings are in contemplation at the Henley Union to accommodate 100 children, with residences for master and mistress. The plans (prepared by Mr. Frederic Haslam, architect, of Henley) have received the approval of the Poor-law Board, and it is thought that tenders will be invited shortly for the erection.

KELLY COLLEGE. — A short time since we announced that this building would be erected somewhere in Tavistock. We are now informed that Mr. Hanson, of Clifton, the architect of colleges at Malvern and Clifton, has recently visited the several sites offered by the Duke of Bedford; and has advised the acceptation of one known as the Parkwood site. This occupies a hillside, with a southern aspect, is about 20 acres in extent, has command of fine views of the valley of the Tavy and some of the Dartmoor hills, and possesses a good supply of water.

GREAT BLAST OF GRANITE.—On Tuesday afternoon a great blast was successfully fired at Bonawe Granite Quarries, Argyleshire, under the superintendence of Mr. Sim, the proprietor. The mining operations preparatory to the blast have occupied about two years. The perpendicular rock face, measuring about 100ft. square, was pierced below the centre by a level tunnel 4ft. high and 2½ft. wide, which ran straight inwards for 50ft., and then branched off into two headings at right angles 13ft. and 15ft. long respectively, each terminating in a large chamber for the reception of the gunpowder. On Saturday last, arrangements having been completed, about four tons of powder were deposited in the chambers, and the entrance was closed with stones and Roman cement. The train was fired on Tuesday at 2 p.m., by means of a powerful galvanic battery; and immediately, with a smothered subterranean sound, the mountain side seemed to heave slightly upwards, and then subsided into the quarry to the extent of many thousand tons weight.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence]

To OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—F. G., J. M. S., M. T & Co., G. G. H., J. V., W. M. & Co., B. Wheeler, J. C. J., J. P. S., W. B. C., C. B. A., G. W., H. H.

JOHN MALCOLM.—Sketch came too late.

C. S.—Water Basins to hand.

H. HATFIELD.—It is not the same work; in fact, an inferior one.

G. R. S.—The MS. to hand.

J. D.—We cannot.

H. HIGGENS.—You will see from notice in another column that the "Sketch Book" is finished

SKETCH BOOK.—All unreturned drawings will be returned on receiving necessary instructions.

ERRATUM.—In our report of discussion at the Institute on S Thomas's Hospital, in Professor Kerr's speech, page 84, middle of third column, for "barnacles" read *marbles*.

Correspondence.

KITCHEN BOILER EXPLOSIONS.

(*To the Editor of the* BUILDING NEWS.)

SIR,—It appears to me that there is much misunderstanding as to the cause and prevention of these accidents. Perhaps the better title to head remarks on this subject would be Hot Water Apparatus Explosions, as the ordinary kitchen boiler, as fitted in most houses, cannot explode. The public may ascertain the dangerous kind by mere inspection; the common self-acting range boiler has a lid, removing which cook can inspect and clean the boiler; but the boiler most liable to explosion cannot be opened for cleaning, &c., except by a workman with proper tools. There is a possibility of a range being fitted with both kinds of boiler.

It is surprising to find how many workmen calling themselves plumbers, &c., are ignorant of the use and construction of these apparatus. Even "Plumber," in your last number, has stultified his excellent remarks at page 74. He ought to be aware that *all* apparatus for heating by hot water are provided with *two pipes* (up and down), or how would circulation, or revolving as he calls it, take place? The cistern is a mere reservoir for a quantity of hot water greater than that contained in the pipes and boiler; it has nothing to do with the circulation, and may be placed anywhere, but of course if below the highest point of the pipes they must be connected, provided with a steam pipe, and the cistern must be closed hermetically; the cistern will *not prevent accidents*. The pipes should have a continued fall, but not only for the reason that "Plumber" gives, for should there be at any part of the length of the pipe a trap or downward bend, steam will accumulate until the pressure equals the resistance, when it will escape with a loud rattling noise, very annoying but not dangerous. I have known this to take place when the up-pipe is too far into the top of the boiler (it is best connected with a flange and four screws); also I have seen the same defect when a trap is formed, when the top of the boiler is set not level or inclined the wrong way. I should like to ask "Plumber" what would happen if the two pipes got frozen? Supposing cook, coming down late one cold morning, hastens to make up a good fire. I fancy "Plumber" would not like to be in the kitchen.

Now, allow me to add one more suggestion. In addition to the fusible plug let a small pipe be carried up the kitchen flue, or close alongside, to a point above the highest point of the cold supply, for the purpose of keeping at least one opening to the boiler, so that the act of lighting the fire would melt any ice that might happen to get in it before the pressure would get to explosion point. There is yet a chance of accident from the cold supply ceasing *at any time of the year*, and cold water rushing suddenly into a red-hot boiler would cause an explosion. To reduce the chance of this happening, I would have the lowest cock so situated as to prevent the boiler from being emptied; the supply of hot water ceasing would give a good notice that something was wrong, and even if this was neglected the fusible plug would come into use.

As all so-called *self-acting* apparatus are dangerous, only care and knowledge will entirely prevent these accidents from happening.

I have just heard that the last apparatus that I superintended the construction of had a near chance from an accident through the ignorance of a workman who was called in to *make sure against accident* during the late cold weather. The fire had been kept out from fear, as the pipes were frozen, and the first thing this clever man did was to disconnect and plug up a safety pipe that I had insisted upon being fixed up the kitchen flue, and then he made a fire. Fortunately, the ice melted before any accident happened. T. S.

IMPEDIMENTS TO SANITARY PROGRESS.

SIR,—As the force of a particular case, when used to illustrate a general proposition, depends upon the correct statement of facts, I am sure you will permit me to point out several errors in the article headed as above in your issue of the 10th inst. It is stated (1) "That in the parish of Beckenham a sewer authority has been formed," and (further on) "a vestry meeting appointed a sewer authority." The latter words show in what sense the former are to be taken. The statements are inaccurate. The vestry of Beckenham has not appointed, and cannot appoint, a sewer authority. It is itself a sewer authority, as is also the vestry of every parish in England and Wales, except where the local authority consists of mayor, aldermen, and burgesses, or of commissioners, &c., under local Acts of Parliament (see Sewage Utilization Act, 1865), and (quoting the words of the Home Secretary in his "Circular of Information as to the powers and duties of Sewer Authorities"), "It is important to remark that the powers and duties of these authorities are not optional, to be taken up, dropped, or declined at will. The powers are given and the duties are imposed *compulsorily by law*." These duties, then, being imposed on "the vestry" compulsorily by law, what it has done is what it is authorised to do by the 4th section of the Sanitary Act, 1866; it has appointed a committee "at a vestry meeting specially convened for that purpose." It can at any time alter the constitution of or dissolve the committee. The committee are "the agents" of the vestry, and their appointment does not release the vestry from any statutory obligation as a sewer authority.

It is here obvious what care the legislature has taken to secure the protection of the ratepayers. (2) It is stated in the article "This authority forthwith employed a surveyor, &c." This authority is intended in the article to mean the authority appointed by the vestry—*i. e.*, the committee. This statement is also entirely incorrect, the surveyor being employed and his report being ordered by the vestry itself more than three months before the appointment of the committee. (3) "This sewer authority" is formed under the Utilization Act, 1867. This also is inaccurate, the sewer authority being created as before stated compulsorily by law under the Act of 1865, and "the committee" having been appointed as before stated under the Act of 1866. (4) "No steps have been taken," &c., "to consult the general feelings of the ratepayers." This statement and much that follows is disposed of by the considerations that the report of the surveyor has not been adopted, that it has been referred by the vestry to the committee "with instructions to consider and report thereon to the vestry as speedily as possible, and that the committee has sat on four different days for more than 13 hours altogether for the special purpose of gaining information from and hearing the views of, the ratepayers, and that every ratepayer was invited by notice sent to his house to attend that one of these meetings most convenient to himself. (5) "All authorities with rating powers should be elected directly from the ratepayers." This is already secured by the existing law (see Sewage Utilization Act, 1867, section 17). The writer of the article would seem to suppose that "the committee" is invested with rating powers. This is not and cannot be the case. The rate has to be made by the overseer upon receiving the precept of the vestry, not the committee. (6) The vestry is spoken of as meeting at "12 o'clock at noon." At this hour, as I am informed by an old inhabitant, the vestry of Beckenham never has met within the memory of man; the usual hour until quite lately has been 9 a.m.; latterly the meetings have been at 5 p.m.

I would only add, that the committee has no objection to any public strictures on themselves. They "represent the general body of the ratepayers" as much as any Member of Parliament his constituents. They will rejoice to see any public notices of their acts or the acts of the vestry, provided such notices are accurate; and for approval of their conclusions, they are content to await the verdict of the ratepayers, "without further reference to whom no new drainage works are to be executed nor any contract for the same made." I ask the insertion of these lines, feeling sure that you will be most ready to correct such mis-statements for the credit of your paper, and to remove any erroneous notions which, on its authority, might gain ground in Beckenham and elsewhere.—I am, &c., EDWARD J. ATHAWES,

Chairman of the Committee of the Beckenham Sewer Authority.

Feb. 15, 1871.

ARCHITECTS AND THEIR ASSISTANTS.

SIR,—I must agree with "Would-be Industrious" that it is very sharp practice on the part of principals to grudge the few shillings their assistants may earn after office hours. I know the "town in the West in which the *meeting* was held."

I believe I am right in stating that in neither of these offices do they supply "quantities" for any work, and yet at the meeting the principals decided that none of their "assistants should be allowed to do so," nor, in fact, any other work they might be able to do out of office hours. I feel sure, Sir, you will agree with me that this *is rather sharp practice*, and shows a very selfish spirit on their part to grudge the few hard-earned shillings to their ill-paid assistants. A little evening employment now and then encourages the younger branches of the profession to be industrious; and it is not only beneficial in a pecuniary point of view, but also highly instructive.—I am, Sir, &c.,

FAIR-PLAY.

COMPETITION, GRAY'S SCHOOL, ESSEX.

SIR,—The statement volunteered by a good old author that "manners maketh man" is one that merits, obtains, and maintains universal credence, and is in receipt of verification perpetually.

From one of those "gentleman of the cloth" who ostensibly devote their talents and energies to the amelioration of their untutored and unenlightened brethren, and occasionally omit to "practise what they preach"—or, at all events, obtain credit therefor—one would scarcely anticipate an entire lack of common courtesy and a palpable breach of good manners.

The next time "the powers that be" at the above-mentioned place obtain a set of drawings in competition and return the same in anything but good condition, without one word of information regarding the award, explanation, or acknowledgment for time and trouble,

"May I be there to see."

I am, Sir, &c., F.

NEW LAW COURTS.

SIR,—If "J. M. L." were one of the initiated, he would *better see* the cause of the great disparity of tenders *tempo* 1871. The difference in percentage between the highest and lowest estimates in the case cited by no means approaches the unprecedented, and only attracts attention on account of the magnitude of the aggregate amount.

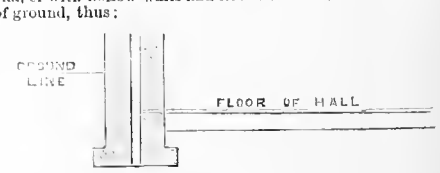
The simple solution of the mystery, to my mind, is that the highest contractors (no rarity, by the way) tendered perhaps for the sake of so doing, for the purpose of keeping their names before the public, and probably to avoid giving offence to the architect by not tendering, and without the remotest intention of securing the job, keeping well out of the way advisedly!

The insinuation in the concluding paragraph, besides being open to misconstruction, is fallacious in argument; sins of commission are quite as frequent as the opposite in quantity-taking, and if an error of the former class is open to correction by the employment of two or more surveyors, does it not afford the very best argument for their employment?—I am, Sir, &c., F.

Intercommunication.

QUESTIONS.

[2125] PROBLEM IN CONSTRUCTION.—Will any of your readers oblige me with a solution of the following problem in construction:—In the case of a hall under a chapel with hollow walls and floor about 5ft. below surface of ground, thus:



will a damp course of asphalte or slates be necessary? The hollow in centre of brick wall will prevent damp penetrating through the walls laterally; if a damp course is required, at what level should it be placed? It is usually a little above the ground line, but in this case I think it should be below the level of hall floor.—A CAUTIOUS ONE.

[2126] PLUMBERS' WORK.—May I ask the favour of a subscriber informing me what is meant by "Lead-soldered tacks"?—F. THOMAS.

[2127] ANCIENT CHURCH ARCHITECTURE.—Will some one kindly inform me where I can obtain a work on ancient church architecture?—W. H. B.

[2128] ISOMETRICAL PROJECTION.—Would some one give me the name of an elementary treatise on isometrical projection, not too expensive?—CUPIDUS DISCENDI.

[2129] MANSARD ROOFS.—Are roofs of this description correctly styled Mansard roofs? If not, what should

they be termed?—F.

[2130] CEMETERY CHAPELS, ETC.—If there are any regulations in force which in any way affect the construction of cemetery chapels, lodges, &c., will some obliging intercommunicant kindly state where they are obtainable?—F.

REPLIES.

[2111] CONE OF RAYS.—If "Student" draws two lines to meet at the station point to meet at an angle of 60° till they cut the picture plane he will have the diameter of the base of the cone of rays; generally speaking, either the station point, or the point of distance, or the length of the line of direction are given on the examination papers. If "Student" will send me his address I will give him more information.—T. MALLINSON, Gargrave, Leeds.

[2120] DRAWING BOARDS.—The untoward circumstance described is common on the use of new boards. The cause is this, the wood being soft and absorbent, the moisture passes from the wet paper into the board, and which thereby expands, rendering to great extent nugatory the expansion of the paper. When worked on, the paper from the heat of the body tightens, but as the board has not dried thoroughly the moisture from it loosens the paper when put away. When by use the board gets ingrained with dirt and grease it is less absorbent, and the evil is not as great. If the paper is thoroughly soaked on another board until the pasting is done the evil will be abated, but the only perfect correction would be to have the board painted. I wonder the makers of drawing boards do not adopt this improvement, having the drawing surface painted one coat in oil, and then rubbed down to a perfectly smooth surface. Such surface would be better to draw upon, by not absorbing the wet it would be better for straining paper on, and would be, I think, less liable to warp. Ink spots could also be wiped off it, and so prevent another common disaster in such marks appearing through the strained paper.—P. E. M.

[2120] DRAWING BOARDS.—In answer to query regarding the slackening of drawing-paper, I can only say it is not the fault of the board, as "Annoyed" seems to think; but simply that he, when straining the paper, did not wet it sufficiently. When next he is straining paper, let him well saturate the same, and glue or paste while wet, drying the edges of paper before applying the glue, &c.—G. P. B.

[2121] S. PANCRAS' CHURCH.—In this week's number I find the following inquiry by "A Young Architect." "Is the present old S. Pancras church 'good old architecture or modern?" I beg to inform it is only 24 years old (Messrs. Gough & Roumieu, architects). The old church was principally late Tudor. When it was pulled down to be rebuilt, several small Norman columns, pilaster piers and other remains of a Norman edifice were found among the materials used in the wall, leaving no doubt but that the original church had been a Norman structure which had been at some time completely rebuilt and part used as building material in the reconstruction. In answer to another inquiry in your correspondence, relative to the Saturday half-holiday, I beg to say that my clerks always have had it, leaving at 2 o'clock from the very commencement of the holiday movement.—R. L. ROUMIEU, 10, Lancaster-place, Strand.

[2121] OLD S. PANCRAS' CHURCH.—The church is modern Norman, and of very poor quality.—P. E. M.

[2124] CRUSHING WEIGHT OF STONES.—The following are the fracture and crushing weight of cubes of stones with 2in. sides

	Weight producing first fracture. Tons cwt.	Crushing weight. Tons cwt.
Ancaster (oolitic limestone)	3 $0\frac{72}{100}$	4 $3\frac{49}{100}$
Darley Dale (white sandstone)	11 $2\frac{64}{100}$	12 13
Mansfield (white sandstone)	4 $11\frac{8}{100}$	9 $7\frac{22}{100}$

One fourth of the above will give the fracturing and crushing weights of cubes of stones with 1in. sides, or in practice for every superficial inch on the bed face of the stone.—W S., Hull.

WATER SUPPLY AND SANITARY MATTERS.

EXETER.—Prompted, doubtless, by the successful experiments which have been made at Romford and elsewhere in the application of sewage manure to agricultural purposes, the inhabitants of Exeter have determined to establish a company entitled the City of Exeter Sewage Manure, Irrigation, and Farming Company, having for its object the utilisation in some measure of the now wasted outflowings of large towns and cities. Beginning at home, it is intended in the neighbourhood of Exeter to carry on a farm manured by the sewage of the city. The capital of the company is to be £40,000, in £5 shares.

Our Office Table.

ECONOMY (?) AND THE NEW LAW COURTS.—Some calculations just made respecting the cost of the new Law Courts are not, as a weekly contemporary justly says, flattering to our economising Government. £800,000 was laid out on the site, between four and five years ago. The loss of interest, therefore, amounts to some £26,000 a year, not reckoning on the compound principle. The contract of the excavation of the site has been taken for £36,000; therefore in less than a year and a half the interest would have paid for the whole of this operation. If the work had been commenced three months ago, 2,200 men could have been employed during the whole of the time at £1 a week each by one year's interest. It would be interesting to calculate how many cases of relapsing fever, how fine practices on the part of workhouse guardians, how many deaths from starvation, might have been prevented by laying out this sum on the howling wilderness which must be cultivated some time.

MR. BURGES'S NEW WORK.—We see that several copies of Mr. Burges's work are now at the disposal of the public in consequence of some of the subscribers not having taken up their subscriptions. This, of course, is a natural consequence of the great delay in bringing out the work, and should be a warning to other gentlemen engaged in similar enterprises.

FAT CHURCHYARDS.—We had something to say about the condition of a Devonshire churchyard a few weeks back. According to the *British Medical Journal*, Leeds is doing its best to establish a forcing ground for disease in the Burmantofts Cemetery in that town. The ground is evidently overcrowded with corpses. The soil of a newly-dug grave lately opened was so tainted that the mourners were choked and sickened, and the priest who read the service had to turn his back on the grave and hurry away to recover from the faintness and sickness which overcame him! Truly a state of things at once scandalous and dangerous to the people of Leeds—not, however, that they stand by any means alone. We know of one London cemetery in which, after a heavy fall of rain, no disturbance of the ground is needed to indicate which portions of it should long ago have been closed.

NUNHEAD AND GREENWICH RAILWAY.—The works upon this line are being taken in hand, and it may be expected that they will be in such a forward state in a month or two as to afford direct means of communication between Greenwich and the Crystal Palace, *via* Nunhead. The line is about two miles in length, and there will be three stations, one at the terminus *pro tem.*, at the foot of Blackheath hill; an intermediate one at the crossing under the highway at the top of Loampit-hill, Lewisham; and the third at the junction at Nunhead of the new line with the South London line, which is worked by the London, Chatham, and Dover Company. Only one line of rails has been laid as yet; but a double line is to be put down. The work is of the best character in strength and fitting.

THE NEW COMMISSION OF SEWERS.—The Lord Mayor on Tuesday opened the new Commission of Sewers for the City at Guildhall. The ceremony was followed by an animated debate on the election of chairman of the Commission. In the result the election fell upon Mr. Deputy de Jersey by 37 votes to 22, in a court of 59 members.

MEETINGS FOR THE ENSUING WEEK

MONDAY.—*Royal Institute of British Architects.*—"On the Roof of St. Pancras' Station." By Mr. W. H. Barlow, C.E., F.R.S. 8 p.m.

Architectural Association.—"On Limes and Cements." Lecture III. By Lieutenant-Colonel Scott, R.E. 7.30 p.m.

Society of Engineers.—Discussion on Mr. E. Crompton's paper "On the Economics of Railway Maintenance." 7.30 p.m.

TUESDAY.—*Institution of Civil Engineers.*—(1) Discussion upon "Pumps for Low Lifts;" and, time permitting, (2), "Account of the Balance Dock at Pola, on the Adriatic." By Mr. Hamilton E. Towle, of New York. 8 p.m.

FRIDAY.—*Architectural Association.*—"On the Recent Works at All Hallows' Church, Lombard-street, with Remarks on Sir Christopher Wren's Churches." 7.30 p.m.

SATURDAY.—*Architectural Museum.*—"On the Casts in the Museum Collection." By J. P. Seddon, F.R.I.B.A. (Visit of Members of Architectural Association). 3 p.m.

Timber Trade Review.

PRICES 15th February, per Petersburg standard:—Bollsta mixed yellow, 8*l*; Dram 2nd yellow, 7*l* 10*s*; do 3rd yellow, 7*l*; Gothenburg 3rd yellow, 8*l* 5*s*; Hudiksvall 1st yellow, 9*l*; do 2nd yellow, 8*l* 10*s* to 10*l*; do 3rd yellow, 8*l* to 9*l* 10*s*; Petersburg 1st yellow, 10*l* 10*s* to 11*l* 15*s*; Munksund 1st yellow, 9*l* 5*s*; Quebec 1st dry floated yellow pine, 12ft. 3 × 11, 17*l*; do 1st floated, 16*l*; do 2nd floated, 12*l* to 12*l* 5*s*; do. 2nd dry floated, 12*l* 10*s*; do 3rd floated, 9*l*; do 3rd dry floated, 9*l* 10*s*; Sikea yellow mixed, 8*l* 15*s* to 9*l*; do 3rd yellow, 7*l* 15*s*; Sandviken mixed yellow, 8*l* 10*s*; do 3rd yellow, 7*l*; Skonvik mixed yellow, 9*l* 5*s* to 9*l* 10*s*; Sundswall mixed yellow, 8*l* 10*s*; do 3rd yellow, 7*l* 5*s* to 7*l* 10*s*; do mixed whitewood, 8*l* 10*s*; do 3rd whitewood, 7*l* 10*s*.

Per 120 12ft. 3 × 9.—Bathurst unsorted white spruce, 12*l* 5*s* to 13*l* 5*s*; Miramichi unsorted white spruce, 12*l* 5*s* to 14*l* 5*s*; Quebec 1st white spruce, 16*l* to 18*l*; do 2nd, 16*l*; do 3rd, 15*l* to 15*l* 5*s*.

Quebec black walnut timber, 2*s* 6*d* to 2*s* 8*d* per foot cube; Quebec hickory, in at 4*l* 5*s* per load; Quebec birch, 2*l* 15*s* per load; Sundswall fir timber, 2*l* 15*s* per load; Stettin oak, 4*l* 17*s* 6*d* per load; crown Memel oak, 5*l* 15*s* to 6*l* 15*s*; crown Memel, 4*l* to 4*l* 10*s*; Riga, 3*l* 5*s* to 3*l* 7*s*; United States pitch pine, 3*l* to 3*l* 15*s*; Sabicu, 6*l* to 8*l*; Indian teak, 12*l* 10*s* to 13*l* 10*s*; African oak, 6*l* to 7; British Guiana greenheart, 5*l* 10*s* to 6*l* 10*s*; Australian ironbark, 6*l* to 6*l* 10*s*.

Memel crown pipe staves, 170*l* to 180*l* per mille; do brack, 130*l* to 135*l*.

Cuba cedar, 6*d* to 7*d* per foot; Honduras do, 4½*d* to 5½*d*; pencil do, 2*d* to 4½*d*.

Per Petersburg standard.—Saguenay 3rd bright yellow pine, 8*l* 10*s* to 9*l*; do 2nd red pine, 10*l* to 11*l*.

Dantzig 2nd crown deck deals, 14*s* per 40ft. 3in.

Petersburg lathwood, per fathom of 216 cubic feet, 5*l* to 6*l*.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

WHITCHURCH, Feb 20.—For the erection of town-hall and markets in Whitchurch, Salop. Local Board Officer Whitchurch, Salop.

WHITCHURCH (Whitchurch Local Board), Feb. 20.—For the erection of town-hall and markets in Whitchurch, Salop. S. M. Lockwood, architect, 85, Foregate-street, Chester.

WAR OFFICE, Feb. 25.—For works and repairs, and supply of building materials to War Department. Buildings and property at Ashton-under-Lyne, Birmingham, Bradford, Burnley, Bury, Carlisle, Chester, Coventry, Fleetwood, Hartlepool, Isle of Man, Leeds, Liverpool, Manchester, Maryport, Newcastle-on-Tyne, Northampton, Paull on-the-Humber, Preston, Scarborough, Seaham, Sheffield, Stallingborough, Sunderland, Tynemouth, Weedon, Whitehaven, and York, including the surrounding neighbourhoods, from the 1st April, 1871, till 31st March, 1874.

BOLTON.—Contract C.—March 3.—The Corporation of Bolton are prepared to receive tenders for the joiners' work, plastering, painting, glazing, and plumbers' fittings required for the completion of the new town-hall. The drawings and specifications may be seen, and bills of quantities obtained, on application at the offices of Mr. William Hill, architect, Park-square, Leeds; or at the offices of Mr. George Woodhouse, architect, St. George's-road, Bolton, between the hours of 10 a.m. and 5 p.m., from the 16th day of January next to the 3rd day of February next. Sealed tenders are to be sent in not later than 12 o'clock at noon of Friday, the 3rd day of March next, addressed to the undersigned at the Corporation Offices, Acres Field, Bolton, and endorsed "Tenders for the Town-hall, Contract C." R. C. Hinnell, Town Clerk.

BRISTOL LOCAL BOARD OF HEALTH, Feb. 23.—For contructing and completely finishing certain intended brick sewers, valve chambers, and other works in "The Avon Intercepting Sewer District." Length of sewers about 7563 yards, varying in size from 3ft. high by 2ft. 6in. wide to 7ft. 6in. in diameter. John G. Heaven, Clerk, Local Board of Health Office, 13, Prince-street.

PORTSMOUTH, Feb. 20.—For the erection of a church at Portsdown, five miles north of Portsmouth. John Colson, architect, St. Swithin's-street, Winchester.

BIRMINGHAM, Feb. 25.—War Department triennial contract for builders' work. Colonel Commanding, Royal Engineer Office, Manchester.

BRADFORD, Feb. 25.—War Department triennial contract for builders' work. Colonel Commanding, Royal Engineer Office, Manchester.

SUFFOLK, Feb. 25.—For the repairing and other work to the parish church of Hadleigh, Suffolk. W. Grimwade, churchwarden, Bank, Hadleigh.

BERWICK-ON-TWEED, Feb. 25.—(1st) Building two tanks, engine and boiler-house. (2nd) Furnishing 30-horse power engine, boiler, pump, &c., and fixing. (3rd) Furnishing 2,700 yards of 9in. cast-iron pipe. (4th) Laying and jointing the same. J. C. Weddell, Clerk to Local Board.

BANKRUPTS.

(TO SURRENDER IN LONDON).

Brian Edwin Abery, London-lane, Hackney, builder. Feb. 28, at 12.

(TO SURRENDER IN THE COUNTRY).

Joseph Cropper, Sheffield, plumber, Feb. 20, at Sheffield—Hammond Parker, Huddersfield, builder, Feb. 27, at Huddersfield.

PUBLIC EXAMINATIONS.

March 5, W. S. Hollands, Richmond-terrace, Clapham-road, architect—Feb. 28, H. Williams, Sedgley, fire brick manufacturer.

DIVIDEND MEETINGS.

Feb. 21, J. Parker, Kingston-upon-Thames and Surbiton, coal and lime merchant—March 9, J. Moore, Pickering, Yorkshire, road surveyor—March 7, J. S. Barnsdall, Nottingham, painter—Feb. 24, R. Roberts, West Derby, builder—March 2, T. Baxter, Brandon, Durham, timber merchant—March 7, J. S. Taylor & J. Marsden, Derby, iron-founders.

DECLARATIONS OF DIVIDENDS.

C. W. Wiggs, Waltham Abbey, builder, div. 1s. 5d.—S. Shipp, Bitton, mason, div. 2s. 5d.—E. P. Tilley, Clevedon, builder, div. 1d.

SCOTCH SEQUESTRATIONS.

R. Anderson, Edinburgh, painter, Feb. 15, at 2, at Bowell's Rooms, Edinburgh.—W. and D. Muir, Glasgow, contractors, Feb. 20, at 12.

PARTNERSHIPS DISSOLVED.

Reed & Stephenson, Gateshead Low Fell, joiners—Lee & Stanhope, Belper, painters—Laycock & Thornton, Bradford or elsewhere, plasterers—T. & C. Elwyn, Darlington, joiners—Kerr & Dalziel, Manchester, house painters.

THE BUILDING NEWS.

LONDON, FRIDAY, FEBRUARY 24, 1871.

THE BRITISH MUSEUM.

FEW more interesting, and few more more neglected departments are contained in the British Museum than the Collection of Drawings and Prints, which, however, are very much out of sight. They chiefly illustrate the work of English engravers and designers—but not English exclusively—from the reign of Henry VIII. to the middle of the eighteenth century, and include many admirable examples of Holbein, who, with so many other foreign artists, resided a long time in our country, Rubens, Vandycke, and Hollar among them. The Holbeins are generally outlined with the pen, and afterwards washed with Indian ink; though occasionally a tinge of colour is added. The subjects are usually sacred, varied by sketches of ornament for goldsmiths, jewellers, and armourers, and also for chimney-pieces and state staircases. These works cannot possibly be appreciated by those who undertake to roam through the building in a single day. They are studies of exquisite interest. Again, the Rubens gallery, in chalk, sepia, ink, and tint, leads up most usefully to a knowledge of that great and prolific master. Then there are Vandycks, in the artist's most curious manner, while we should say that the set of Hollars is unique. But they are, nearly all, exhibited in a bad light, crowded upon the screens, and confused in arrangement. Hogarth, Lely, Kneller, and George Vertue are only slightly represented. But the cabinet of engravings is singularly rich, the first impression, in point of order, being an indulgence found in England so far back as early in the fifteenth century; a rubbing from a block, with a quaint inscription beneath the figure:—

> Saint Gregory, with ether Popes and Bishops in fear,
> Have granted of pardon XXVI. days and XXVI. thousand year
> To them that before this image on their knees
> Devoutly say V paternosters and V aves.

To those who take pleasure in such relics of that old art which Sir Robert Strange so gallantly defended against the disparagements of the Royal Academy in its younger days, we would point out an engraved title-page, by Thomas Gemimes, mellowed by more than three centuries of time, a portrait of "Robert Dudley, Earl of Leicester," prefixed to the 1568 edition of the "Book of Judges;" William Hob's "George Chapman, the Translator of Homer," a very admirable specimen; and Hollar's "Ancient Habits of the Officers of the Order of the Garter." But it is not to be expected that any very large section of the public will be attracted by the prints, so that we do not linger among them. The casts from antique marbles and bronzes are likely to be more popular; and here it is amusing to note the cost of gathering together, in this particular respect, the materials of a national museum. For the impression from the celebrated Rosetta stone the trustees paid only six shillings; for the head of the Egyptian Pasha, five; for the lid of a sarcophagus, fifteen. The Assyrian sculptures, in plaster, averaged about two guineas each. Indeed, the highest figure is £18, while some of the models were made for half-a-crown. In fact, there are several cupids which were bought for two shillings each; while a reproduction of the famous Elgin tablet was done for eighteen-pence. Who would not have a private collection upon such terms. Yet these are works which throw a wonderful light upon the human imagination in ages bygone, when the birth of the Arts took place and the ideal genius first mounted its throne. It is in the Sculpture galleries, indeed, that, apart from the library, the principal riches of the museum exist; though, once more, it is to be remarked how callously the populace saunters through them for the simple reason that they are not understood. A slight explanatory description, which might be printed within the space of a postal-card, and the substitution of English for Classical terms, might go far towards rendering the institution more educationally valuable. What is the use of telling the working, or even as a rule, the middle classes, that they are gazing upon a votive cippus? What is the meaning conveyed to the illiterate or half-cultured mind? Or, that the next object is a terminal statue? We believe that the public might be treated far better than it is in these matters, for often a concourse would be drawn, could it only comprehend the thing to be seen, by that colossal head of the Goddess of Wisdom, so stern of countenance, with the twisted locks, the serpent—emblem of vigilance—on the summit of the helm, angry and menacing; or that lovely funeral urn, in form not excelled by the Cellini ewer, which gives us indubitable testimony to the costumes worn by the Romans and the barbarous Germans in battle (the former, frequently, wearing none). But whose ashes lay in that silent urn, with its borders of delicate ivy leaves, and lid with the graceful cluster of acanthus? Vain to surmise. Its date, even, is not known. A brief pause, aided by a slight explanatory label, would increase tenfold the significance of the caryatid, or roof-supporting figure, which is among the chief treasure of the collection. Superficially, it seems nothing more than the figure of a prond and melancholy woman. Look again, and it tells us of the dress and ornaments used by ladies in that distant period—all elegance and modesty as they were; the large tunic reaching to the feet, the shorter robe above, the mantle floating from the shoulders, and fastened over them by buttons (why should buttons be called *fibulæ* in penny catalogues?); the fashion of the hair, curled, worn full round the forehead, and confined by ribbons; the ear-rings, in the shape of flowers; and the double necklace. These points should be made intelligible, at least to all sightseers who care to be informed. The marbles, too, which illustrate antique workmanship and taste, including the superb Roman candelabra, might be of eminent use to our art-workmen, were it not that a selfish and pedantic system precludes them from making use of the Museum as a school. The unsurpassed Bacchanal vase, literally fringed with figures of charm and power; the marvellous Venus, composed of two pieces, joined above the thighs with a cunning so subtle that the joint cannot be detected, and half-draped below the rounded splendour of the bust and waist with a material of a lighter tint; the sacred fountain of marble, in the centre of which a piece of leaden pipe still remains—a remarkably interesting circumstance—and, moreover, displaying in its decorations the dawning of a new taste; that mighty Herculean head, from the Grecian chisel, evincing, in its turn, a fresh development of art. All these should be made to speak more for themselves. We shall not now, however, dwell longer upon these marbles, since the opportunity will recur; but we have said sufficient, perhaps, to explain our general meaning. This great Ionic temple is silent when it should have a voice. Thus visitors approaching from the street perceive a series of figures on the tympanum of the portico; but they are blind as to the allegory, in which man is imaged emerging from a rude savage state through the influence of religion, becoming by degrees a hunter and an agriculturist, quitting the patriarchal state, inventing Paganism, dwelling in cities and worshipping the arts, looking to the sun and stars for a Deity; discovering mathematics, the drama, poetry, and music; and thence rising from heathenism to the Christian Era. As it is, this group of gilt is less regarded as an object of admiration than as a dove-cot for the pleasant pigeons that coo there all the day. However, we are promised that the chaos shall partially cease, and that the words *Fiat Lux* will be spoken, even in these dark and half-buried recesses of Bloomsbury, which, with at least a hundred guineas' worth of books upon their shelves relating to the British Museum, are so dim to the common eye.

NEW HOUSE FOR THE SOCIETY FOR THE PROPAGATION OF THE GOSPEL IN FOREIGN PARTS, DUKE STREET, WESTMINSTER.

THIS society, after many years' search for a house as a suitable centre for its work, has recently purchased the freehold of No. 20 Duke-street, Westminster, and has placed it in the hands of Mr. Butterfield, as their architect, to be adapted to their wants. The alterations which have been made in it comprise, firstly a new frontage towards Duke-street; and inside, in addition to the usual offices for secretaries and treasurers, a small library and museum and an ample board-room and chapel have been formed.

Mr. Butterfield has, under these circumstances, produced a work of considerable interest and individualty, as might be expected of him. The materials are brickwork of various colours for the walling, and freestone for the dressing. There is much irregularity in the general disposition of the various windows of the two lower floors, and diverse treatment of their details. The portal, an erection of freestone, in slight projection from the rest of the façade, has a depressed and two-centred arch, and bears above its cornice a sort of blank parapet, with a panel rising in the centre and enclosing a cross. Folding-doors, with a fanlight in the arched head, occupy the doorway. A pair of two-light windows on the right hand side of the portal, with trefoiled heads, have a shallow buttress, as a framework on either side enclosing them, and rising to the sills of the windows above, the space between the two sets of windows being panelled in stonework. A two-light and a single-light window on the other side of the portal are without this decoration, and a band of diapered brickwork of varied colouring runs above them, marking the division of the floors. A similar band is continued above the ceiling cornice at the level of each of the superior floors. On the first floor there is one large composition of three lights with arched head, with two cusped circles in it, and panelling below the opening a little to the left of the portal; this also has a quaint framework formed by corbelled out buttresses carrying canopies; on the other side are a pair of two-light windows (plain, but of a strange lenghty proportion) over the centres of those described to the floor below. The second floor has four similar but shorter two-light windows, ranged at equal distances apart, and not therefore corresponding with any of those below them; and above them is a deep parapet and four dormer windows to the roof, which again have some trappings in the shape of corbelled-out buttresses. The effect of the whole is somewhat queer and bizarre, and in point of detail neither very pure Gothic nor very charming. In this example, as in Keble College, Oxford, Mr. Butterfield seems to have altogether changed his style from that in which he wrought the domestic buildings around his church in Margaret-street, and we confess we do not think the more recent an improvement. Still, it is certain that time and London smoke will soon tone down the startling look of this work, which is somewhat at present in what has been called the streaky-bacon style; and there is nothing coarse in the forms, although a certain ungainliness in certain of the proportions and features. The monotony of most of our streets, and of this Duke-street among them, is so depressing, that almost any change is for the better, and we are thankful there-

fore that Mr. Butterfield has in this manner enlivened it. We cannot help thinking, however, that the probable not far-distant demolition of the whole neighbourhood, which has been marked out as the site of New Government Offices, has made this able architect less careful than he would otherwise have been as to the character of his work, and that it is only to be looked upon as a temporary makeshift at a limited cost.

SUN-BURNERS.

LIGHTING our dwellings and public buildings by means of gas has now become so common that it seems hardly possible to realize how our grandfathers managed in their day with such dim and troublesome illumination as oil lamps and candles then afforded. The convenience of gas is so great, its use saves so much domestic labour, and its application is always so immediate, that housekeepers are induced to overlook many objections that accompany it, whilst in places of business and public buildings, no other means of lighting seems possible, or to be thought of. Besides the supply of artificial light, gas is capable of being made most useful in many other respects about a building, as for instance, for heating and for cooking; for these latter purposes a large number of useful machines are made, but in addition to these, gas may be made, far more generally than has yet been the case, a most effective means of obtaining artificial ventilation. But little has been done so far towards this result, and yet possibly no motive power is so certain and so easily applied. The only approach to such an intention is to be seen in the sun-burners now greatly in use; but even in these machines the ventilation is rather subordinate, and a result growing out of the necessity for getting rid of the enormous heat generated by the combustion of gas itself than an intentional means of relieving the atmosphere of the apartment in which the sun-burner is placed. The principle of the sun-burner is simple, and its application only attended with such practical difficulties as a skilful mechanic can encounter. The machine itself consists of a certain number of burners placed close to the ceiling, enclosed within a glass frame of almost any shape, and capable of great variety of ornamentation, and so constructed that the heated air generated by combustion of the gas is, or ought to be, rapidly carried off into a special flue and discharged into the open air. As an appendix to this, an aperture is made in the bottom of the enclosing case, and a tube is carried also up into the air-duct through which the heated atmosphere in the upper part of the room may be drawn off, and the ventilation of the apartment thus, to a certain extent, be secured. In effecting this, the usual difficulty—down-draught—occurs, and an improvement in the shape of a self-acting valve has been added for its cure. Such, briefly, are the leading features of the sun-burner; an important improvement in our means of gas illumination, and which, on account of its growing use, is well worthy of some special examination and attention.

The first thought that would naturally occur to an intelligent examiner, would be the waste of lighting power consequent on its position so near to the ceiling, by which only reflected rays, and those too downwards, the worst conditions under which they could be conveyed, and the loss of all direct and diffused light. As a consequence, the consumption of gas must be enormously out of proportion to the amount of light obtained, and on inquiry it was found that the gas required for such a sun-burner as would be sufficient to properly light a certain area, would be three to four hundred per cent. beyond ordinary what open burners would consume, and this especially is the case in rooms of moderate size; for instance, an apartment which would be abundantly lighted by five or six fish-tail burners, as ordinarily applied, would require from twenty-one to twenty-five if enclosed within a sun-burner. For very large spaces, such as the interior of theatrs, concert-halls, and the like, the disproportion is not so great, whilst the concentration of light to one central point has many reasons for preference. There is then no saving in cost of gas in the use of a sun-burner, so it must next be questioned what advantages it possesses over other modes of lighting. The first, undoubtedly, is the avoidance of the super-heated air engendered by open lights; but this advantage, apparently evident as at first it may be, is practically not quite so positive. The amount of heat produced by the sun-burner itself is enormous, and rapid as the out-draught may be, the surface of the case becomes so greatly heated that the temperature of the air near the ceiling becomes quickly raised, and in case of an ordinary room of average height must be a great inconvenience. That even this defect may be guarded against will presently be seen; all that now is attempted is to show the action of the sun-burner as it is in every-day operation. The next advantage claimed is the remedy it affords for the deleterious effects of the escape of the results of gas combustion necessarily evolved in the illumination of brilliantly lighted rooms, and this may certainly be conceded, and is a most important point. Could some certain means be made available by which these evils could be avoided in other modes of gas lighting, all the really practical objections to the universal use of gas in our dwelling-houses would be met. This is a question well worth the attention of chemists, who, with positive effects to deal with and such tangible agents as carbonic acid to encounter, should be able to devise some adjunct to gas combustion which might alleviate or remove all these serious evils; possibly, some mechanical contrivance acting upon a vaporizer charged with a proper chemical might be contrived, which in action would not only neutralize the deleterious effects alluded to, but would also assist the ventilation of the room. A fine spray of Condy's Fluid largely diluted, or its evaporation by means of saturated cloths, will, it is known, greatly relieve gas-poisoned air, and until some better plan can be suggested, should certainly be tried. An ornamental saucer appended to an ordinary gas-light, containing cotton or a sponge saturated with such a mixture, will be found to cause an agreeable change in the quality of the air when the room becomes heated.

The advantages claimed then for the sun-burner in its present improved form, are a more agreeable temperature and a purer internal atmosphere, both so important in a sanitary point of view as to counterbalance the additional expense of the large consumption of gas. At first the apparatus so called was a clumsy, unsightly affair, consisting of a large sheet-iron funnel and tube, and under it a circular pipe with burners regularly placed around, the whole casting a black shadow on the ceiling to the destruction of all decorative effect. Added to this, no contrivance had been thought of (or at all events provided) for the prevention of down-draught when the gas was not lighted, so that in the day time the rush of cold air was so unbearable as to suggest the lighting of the gas with its artificial day light as the smaller evil of the two. Ultimately, after many transitions, a perforated frame filled with mica was substituted for the sheet-iron in large machines, and a strong glass globe for the lighting of smaller rooms. A self-acting valve, so constructed as to open simultaneously with the act of turning on the gas and to close when shut off, was contrived, which has satisfactorily accomplished the stoppage of the down-draught. In this form the sun-burner offers a means of depriving the use of gas for lighting large rooms of most of its objections; it remains now to inquire how far the present apparatus may be made subservient to still more general utility.

The machine itself, to begin with, is a patent, and its application requires certain structural conditions which are not always favourable, hence the cost of providing the sun-burner is considerable and unequal. The actual lamp, so to speak, itself is not a heavy item of expense compared with other well-made gas-fittings; it is in the provision of flues and appliances that the working bill gathers a formidable length. Thus it will be seen that the estimates generally supplied give first but the cost of the sun-burner only, without flues and fittings; then comes cost of self-acting valve, then glass decorations, and lastly flues, ornamental or plain, black or galvanised; and to the whole the time of fitting up must be added. As an example, suppose a twenty-jet burner is required (which would be one of small size, suitable for a moderately-proportioned billiard room), the cost of the various patterns of the lamp alone would be from £10 to £17, the valve £5, an 8in. flue pipe, if of plain make, would be from 2s. to 2s. 6d. per foot, a wind-guard or other chimney terminal from £1 to £1 10s., and if ornamental work was required the glass decorative fixtures for a burner of this size would range from £7 to £18. Thus the cost of appliances without fitting up and labour would be from £26 to £46, allowing 10ft. of flue pipe. The further and generally much heavier cost would be caused by the adaptation of the structural arrangements of the already erected building and in an instance under personal observation, the expense of fitting up a burner of about this size in the dining-room of a country house was nearly £200. It will be seen then that for domestic use the sun-burner is not entirely suitable in its present form, although of course, in providing for its introduction in new buildings, the cost of fittings could be most materially diminished. There still remain, however, the objections of great heat derived from the lamp itself—only partially obviated by the hot-air duct which forms a portion of its working features—and the enormous quantity of gas consumed.

It is fair to state that the manufacturers of the sun-burner admit the objections to the use of the light in ordinary dwellings and in rooms of average height, and frankly tell inquirers that they cannot say there is any economy in the arrangement, and that the direct heat is very considerable. Admitting these defects, it is incumbent on all interested in so vital a matter as the comfort and healthfulness of our houses, to endeavour to devise modes of lessening existing objections, and to bring out the advantages which this principle of illumination undoubtedly affords.

In the first place, the great consumption of gas. Much of this is due to the unfavourable position of the burner itself. It is so close upon the ceiling that the rays of light can be deflected downwards only, all lateral and diffused light being entirely lost. This it seems might to an important degree be remedied by modifying the form of the lamp, and by placing the jets, not in a circle on the same plane, but employing larger burners, fewer in number, and in an inverted pyramidal arrangement by which at a lower point one powerful light might burn, and four others some inches above it. Without drawings it is difficult to suggest this, but an examination of a sun-burner will show that no structural detail essential to its principles of action need be interfered with by the change. The frame would come lower in the room, it is true, but it might be made a more ornamental feature, and the light thrown from its curved or sloping sides would be evenly diffused across the ceiling, and help most materially to remedy one existing defect which artists loudly complain of in regard to the shadow or unfavourable light cast upon ceiling decoration. The decorated glass casings already supplied for sun-burners require but slight modification to fit them to the arrangement of burners thus suggested, and as each burner is already a group of smaller jets it would be easy to modify and increase the size of each and pro-

portionately diminish the number. It is a fact well known that the larger the burner the less the consumption of gas in proportion to the illuminating power; so that a good economist would do well to double the size of his jet, and with the same pressure of gas as before he will obtain twice the amount of lighting power.

(To be continued.)

METROPOLITAN RAILWAY AND TRAMWAY PROJECTS.

MR. HAYWOOD has presented to the Corporation of London his usual annual synopsis of the distinguishing features of the various schemes for the promotion of railways and tramways which in any way affect City interests.

The first of these is the Pneumatic Railway, projected to connect Broad-street with the proposed Metropolitan station at Cannon-street, which, starting between Bow-lane and Bread-street, will pass under Queen Victoria-street, Mansion-house-street, Threadneedle-street, Old and New Broad-street, and Liverpool-street, to Broad-street, where either an exchange station or a junction will be made with the other railways which will terminate at that spot. The tube will be constructed either of iron or brickwork, and 11ft. high, and the whole of the work will be executed by tunnelling. If constructed, this railway will complete the Inner Circle, enabling passengers by the North London and North-Western lines to reach the West End without leaving the railway system.

The Eastern Metropolitan Railway has for its object the formation of an underground line, commencing, by a junction, with the Underground Railway (Tower-hill Extension) at Meeting-house-yard, proceeding thence by a curve in a south-easterly direction to Whitechapel High-street, near Leman-street. It will be continued along Whitechapel High-street, the Mile-end, and Bow-roads to the North London Bow Station, effecting a junction by an interchange station.

The Holborn Viaduct Station is contemplated for the joint accommodation of the London, Chatham and Dover, the London and South Western, and the London, Brighton, and South Coast Railways.

The Bills for the enlargement of Billingsgate and Leadenhall Markets are introduced by the Corporation itself. The first-mentioned scheme contemplates the enlargement of the fish-market, and schedules the whole of the Custom-house, with its quay, and the whole of Dark-house lane and the adjoining property. To Leadenhall-market it is proposed to add a space, included by a line on the eastern side of Gracechurch-street from houses 72 to 91 inclusive, Half Moon-passage, Leadenhall-place, Lime-street, and Ship Tavern-passage.

The Government introduce the Bill for erecting the New Mint, and have selected as its site the open space on the Victoria Embankment next the Gas Works.

Five tramway schemes seek Parliamentary sanction:—The *Oxford-street Line*, which, commencing in the west, enters the City at Holborn-bars, passes through Holborn, down Charterhouse-street, turning northwards into Farringdon-road; the *Holborn Viaduct Line*, starting with a junction with the last-mentioned line at Holborn-circus, and proceeding thence by a double line over the viaduct to Giltspur-street; the *Smithfield Loop-line*, commencing in Farringdon-road by a junction with the Oxford-street Line, and thence to be carried along Charterhouse-street, past the western part of the Meat-market, along Giltspur-street, to a junction with the Holborn Viaduct Line near Newgate-street; the *King's Cross and Blackfriars Bridge Line*, which will enter the City near Charterhouse-street, in Farringdon-road, and effecting junctions with the Oxford-street and Smithfield loop-lines, proceed by a double line along Farringdon-street, New Bridge-street, and Blackfriars Bridge to Stamford-street; and the *Angel (Islington) and General Post-Office Line*, which, entering the City in Aldersgate-street at Fann-street, terminates near Newgate-street.

A committee has been formed to carry out the re-seating and warming of Dunmow church.

The new church schools at Myland, near Colchester, are approaching completion.

OLD LONDON.

"NOTES on Old London, Architectural and Engineering," was the subject of a paper read on Friday evening last, before the Civil and Mechanical Engineers' Society, by Mr. C. H. Rew, hon. sec. of the Society. After briefly touching on the rise and early history of the City, Mr. Rew proceeded to describe the old London Wall, with its several gates, remarking that the most important part of this old civic boundary now standing is a long piece of wall, with a circular tower or bastion at the western end, situate at the back of Cripplegate Church. It is about 20ft. high, has a weathering course about 7ft. from the ground, and seems to have had for a coping a course of gabled masonry. The materials of which the wall was constructed were (so far as existing remains afford means of judging) a yellowish-grey stone, in irregular courses and stones of all sizes, and the mortar is in some places standing quite out to the weather, while the adjacent stone is altogether perishing. Some small portions seem also to have been built of flints, with one or two courses of larger stones for foundations, on which were two courses of tiles of rather more than 1ft. in superficial area, and making with the joint a solid course of about 6in. thick. After referring to the building of the Tower, Mr. Rew stated that bricks were first used for the building of houses in London in the reign of Edward IV.; and in the same reign cisterns and conduits for water were constructed, and the city was first lighted at night by lanterns, but this lighting must evidently have been of the most imperfect and crude description, for so late comparatively as the year 1685 it was thought a very great step in advance of all previous efforts in this direction when Edward Hemming obtained letters patent for the sole right of lighting up London. He undertook to place a light before every tenth door on moonless nights from Michaelmas to Lady Day from 6 to 12 o'clock. As the city grew in size the necessity for a fresh and pure water supply grew stronger, whilst the possibility of obtaining such a supply from the river became less and less. After much squabbling between the citizens and the Corporation as to taking the initiative in carrying out works for supplying the City with pure fresh water, Mr. (afterwards Sir) Hugh Myddelton came forward, and with great difficulty succeeded in completing the well-known New River system. The water first entered the metropolis on Michælmas Day, 1613. The water was at first distributed throughout the City by pipes of wood, principally elm, but the leakage was so great in ordinary weather, and fractures through frost were so frequent and serious in winter, that before long the wooden pipes (of which there were in use 400 miles in the different parts of the City) were replaced by pipes of cast-iron. The cost of the New River was about £18,000. Sir Hugh died in December, 1631, and was buried in the Church of S. Matthew, Friday-street, a building which, in common with so much more of Old London, disappeared in the Great Fire of 1666. Mr. Rew next proceeded to describe the Tower, as it was and as it is. In the north-west corner of the Inner Ward is the Chapel of S. Peter-in-Chains, dating from the year 1272, but a much finer church stood here, built by Henry I. in 1100. As it now stands it is a plain stone building, consisting of a nave and one aisle. The Chapel of S. John, in the White Tower, has an apse at the eastern end, and an aisle on either side of the nave and around the eastern apse. The piers, arches, and walling are of well "axe-dressed" stone, and are of what is known as "thick-jointed masonry"—the thin joint being introduced at the same time as the chisel took the place of the axe in the actual working of the stone, about a century later. Old London Bridge was next described, and its history briefly narrated; after which the splendid church of S. Saviour's, Southwark (more properly called S. Mary Overy), was commended as well worthy of notice, though the choir alone remains of the original church. Passing on, Mr. Rew rapidly reviewed the influence exerted on the characteristics of Old London by the various religious communities—such as the Black Friars, White Friars, Austin (or Augustine) Friars, and Grey Friars, each possessing extensive ranges of buildings. The construction and history of the old Cathedral of S. Paul's were next adverted to; followed by references to the Temple (with its famous church), the Savoy Palace and Chapel, and the old palace of the Dukes of Somerset. The author then dwelt at great length on the Royal Palace and Abbey of Westminster; and leaving the Abbey precincts, and taking an imaginary walk up Whitehall, noticed the Old Whitehall Palace, the predecessor of Inigo Jones's Banquetting Hall. Proceeding past Charing Cross, Covent Garden, Whitefriars, and Blackfriars (as they existed in Mediæval times) were described. Brief references to Smithfield, to the Church of S. Mary-le-Bow, Cheapside (literally S. Mary of the Arches—being so called from its having been the first church which had an arched or bowed ceiling to the crypt), and to the Guildhall, brought a very interesting paper to a conclusion.

A short discussion ensued, the speakers being the President (Mr. J. B. Walton, A.I.C.E.), Mr. A. C. Pain, A.I.C.E.; Mr. W. Meakin, Mr. R. M. Bancroft, Mr. H. E. Hunt, &c.

BOOKS RECEIVED.

Brief Chapters on British Carpentry: History and Principles of Gothic Roofs, by Thomas Morris, architect (London: Simpkin, Marshall & Co.), is an attempt to record the more prominent artistic incidents of carpentry as practised in this country. The author acknowledges his indebtedness to the BUILDING NEWS for the execution of the illustrations, and other facilities which have accelerated the appearance of the work. He might have added for its first appearance, which was effected in these pages, and which renders it unnecessary for us to do more here than mention its separate publication.

The Schools for the People. By George C. T. Bartley. (London: Bell & Daldy). Just at the present time this work will prove of great value. It contains no suggestions or officious pieces of advice as to our future course in the great educational work inaugurated last year by Mr. Forster, but supplies a comprehensive history of the methods of education pursued in this country during the last three hundred years. Beginning with the schools attached to the religious houses, which perished when they perished, to give place to poor-laws, pauperism, and gaols, Mr. Bartley goes on to describe the grammar-schools which next became their inefficient substitutes, the parochial schools, which in their turn, succeeded the grammar-schools—and which in some degree resembled the monastery schools, inasmuch as they were only maintained by the charity and self-denial of the clergy—and the various systems of education which have been on their trial during the present century. The work is well printed and illustrated, and no pains have been spared to render it a standard work for present and future reference.

The Year Book of Facts in Science and Art, by John Timbs (London: Lockwood & Co.), demands, we suppose, the usual mention of its appearance: it is all it merits.

The Student's Guide to the Practice of Measuring and Valuing Artificer's Work. Dobson & Tarn. (London: Lockwood & Co.) Originally edited by Mr. E. Dobson, this work is rendered additionably valuable in the present edition by the introduction of fresh matter by the editor, under the auspices of Mr. E. W. Tarn. The work is well turned out, and will remain a reliable text book.

Atchley's Estimate and Price Book for Civil Engineers and Contractors. (London: Lockwood & Co.) This price book is this year published by Messrs. Lockwood & Co. Its contents are of the same character as usual.

The Essentials of Geometry, by J. R. Morell (London: Griffith & Farran.) Euclid will not probably remain much longer the only required text-book of geometry in our schools. Its defects are recognised even by so great an authority as Todhunter, and its cumbrous repetitions have long been felt to hamper its explanations. The treatise under notice is one of the best attempts we have seen to provide a substitute.

The City of London Directory for 1871 (London: W. H. Collingridge.) This directory is the first of its kind. It is well arranged and printed, and contains, besides the usual features of a directory a variety of useful and valuable matter. Viewed solely as a directory, however, we cannot but think it next to useless. What *is* the use of a *directory* to any business man which confines itself to the limits of the City proper? which shuts out such streets as the Strand and Regent-street, Holborn and Oxford-street, and which for all business purposes belong as much to the "City" as Cheapside or Cornhill.

ARCHITECTS' *versus* ARCHITECTURAL SOCIETIES.

THERE is, and there surely ought to be, a considerable difference between an architectural society and a society of architects. The former may be supposed to busy itself with the fine art, Architecture. Its members may be, but need not of necessity be, professional architects. They may be and they are, in the case of many famous architectural societies, made up in great measure of amateurs—witness the Oxford, the Worcester, the Yorkshire, Architectural Societies, whose amateurs form the very bone and sinew of those vigorous confraternities. These amateur students of the art have, with their Paleys and Pettits, their Pooles, Freemans, and Hugos, their Willises and Cuttses, contributed no little to the advancement of our architectural lore. We have heard architects stigmatise them, in sheer oblivion or downright ignorance of the catholicity of art, as "idle parsons." Such men consider that no one but an architect should write or speak about architecture! We venture to assert that the standard writers on the subject are not ordinarily architects, but amateurs. We happen to possess, naturally enough, practical architects who have written on their art; men such as Chambers, Gwilt, Sharpe, Street, Pugin, Scott, Cresy, Burges, and a few others. It is a *laborious* "labour of love" to think of the few (the very few) names; not so laborious a matter to refer to the amateurs we have named—all of them standard writers on the art—or to add to the list a few more, that will at once occur to every architectural student—Evelyn, Aldrich, Milner, Rickman (no architect when he wrote his "Attempt"), Rock, Fergusson, Ruskin, Leeds, and a host of other amateurs.

Do we say this to the disparagement of professional architects? Not at all. But why do we draw this comparison? Simply to remind our professional readers of a fact they are too prone to forget, that, while every society of architects is, and ought to be an architectural society, capable, like the amateur societies of "idle parsons," of discoursing on the art, Architecture, it by no means follows that every architectural society is a society of architects. The amateur societies have one topic of discussion ever before them—Architecture, the Fine Art; but a society of architects has, or ought to have, two other topics ever in view—their "trade" or practice as architects, and the sciences in connection with its pursuit. Some one the other day assumed (it is an old assumption) that architecture is not only an art but a science. It is nothing of the kind. There is no such a thing in existence as the "science" of architecture. But this by the way.

We say our professional readers are apt to forget the distinction just laid down. They form themselves into clubs of architects and idly let them settle down into mere architectural societies. It is the special weakness of the Royal Institute of Architects to fall into this mistake. It is ever on the alert to emulate the Archæological and other amateur societies in the conservation of national or civic antiquities; to bandy compliments with distinguished foreigners; to profit by the delivery of learned papers by amateurs, clergymen, engineers, barristers, and the like. These things are all well enough in their way; but we wish, when others of even greater consequence to *architects* crop up from time to time in the course of a session, the Institute would not evince so perverse a *penchant* for stamping them out, or, to use a milder phrase, throwing cold water upon them. It is not pleasant for English architects to hear, as they have lately done, that the Institute is not an educating body; nor to see the laudable efforts of the Association to inaugurate and keep up for years an Architectural Exhibition treated with a sneer; nor is it at all encouraging to see Fellow after Fellow rise at a meeting to silence a professional inquirer as to what is and what is not the Institute's view of a question of professional emolument. Matters such as these may be utterly indifferent and uninteresting at an architectural society; but we really do not see how they can be ignored and pooh-poohed at any society of architects.

We should like to see the Institute flourish; it is our only chartered society of architects; and all English architects have an interest in seeing it respected—if only because it *is* a chartered society, and numbers among its members our most distinguished practitioners. The Architectural Association has, however, far higher claims than this to the sympathy of every English architect; and really, without that energetic society to urge it on to action, we often wonder what real good the Institute would ever have effected! The younger society may have failed in establishing the Architectural Exhibition: it is a truly creditable failure; and the memory of the attempt is a possession to be envied. Let us all say of it

Non tam turpe fuit vinci quam contendisse decorum,

and remember that other laudable efforts of the Association have been crowned with success. What to day is the proudest feather in the cap of the Institute? The establishment of the Voluntary Examinations. Would the Institute have ever inaugurated them but for the persistent cry of the Association?

It is pleasant to end with a hopeful allusion. Great credit is unquestionably due to the Institute for what it has already effected in the Voluntary Examination case. It is cheering to learn that these examinations are likely to take a more popular form; that the passed candidates, who already receive a written certificate of merit, are to have some further unmistakeable mark or recognition, such as a minor degree, conferred upon them. Of course not every "graduate" will make a good architect; but while this is true, it is undeniable that every good architect will be a better one by becoming a graduate. We sincerely wish success to the movement. It is one we have for years advocated—the beginning, we trust, of the end so much to be desired; when none but graduates of the Institute shall be eligible as either Fellows or Associates. The step to be taken is worth all the fortnightly papers, all the coffee, all the conversazioni, aye, all "the Consols," put together. These, after all, are but the appendages of a popular architectural society, while the graduate scheme will lift the examining body into the far nobler position it ought long ago to have assumed—that of an Institute of Architects.

S. S.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT the ordinary meeting of this Institute on Monday evening last, Mr. THOS. HENRY WYATT (President) in the chair, a paper by Mr. W. H. BARLOW, C.E., "On the Roof of S. Pancras Station," attracted a numerous audience. The paper was illustrated by several very large and beautifully-executed drawings on background.

The author stated in his preliminary remarks that the large arch which constituted the truss adopted in the S. Pancras' Station owes its origin to the floor beneath it. In order to economise space to the utmost, it was determined to employ iron columns and girders instead of brick piers and arches to support the platforms and rails of the passenger station. One consideration in adopting this plan was the floor-girders across the station formed a ready-made tie sufficient for an arched roof crossing the station in one span; all that was required to obtain a roof of this construction being the arch or upper member of the truss, of which the floor-girders would form the lower member. Amongst other advantages claimed for this arch, one was that as the weight of the roof was carried at the floor-line, and did not rest on the tops of the walls, there was no necessity to make the side walls thicker; for not only was the weight on the top walls avoided, but also the rocking motion from the expansion and contraction of an ordinary roof, which, though it may be mitigated, is not prevented by the use of roller-frames at the feet of the principals, and appliances of a like nature; and farther, as to the question of expansion and contraction of the arched roof, the ties being beneath the ballast the temperature would vary so little that no provision would be necessary, and the only effect would be a slight rise or fall in the crown. Lastly, the adoption of a single arch would not only save the cost of the columns and their foundations, but also that of the longitudinal girder required to connect them at their upper extremities, with a valley drain between the roofs, vertical drain pipes, and other provisions for taking off the water from the area between the centre lines of the two roofs, which would have been about two acres. All the circumstances combined tended to favour the idea of one arch across the station, the remaining question being what depth and form of rib, and what additional material must be employed to make an arch which would retain its form under all the conditions of stress to which it would be subjected. The results arrived at, partly by calculation and partly by experiment, were—

1st. That the depth of the rib must be sufficient to contain all the lines of pressure generated by the dead load, by snow, and by the pressure of the wind.

2nd. That the sectional area of the metal should be sufficient to sustain the whole stress without producing a strain on the iron exceeding 3½ tons per square inch.

3rd. That the arch should be rivetted together with proper joint-plates throughout, so as to give it the advantages of complete continuity.

The additional cost of principals of 240ft. span, as compared with principals of two spans of 120ft., was estimated at about £6,000; but the great object being to obtain perfect freedom in the use of the whole area of the station, unembarassed by columns and other impediments, instructions were given for an arch in one clear span. The total area roofed in is 18,822 square yards; the distance between the side walls is 215ft., and the clear space of the roof 240ft. The arch was made slightly pointed at the top, because it was considered that this form possessed advantages in resisting the lateral action of the wind and to have a better architectural effect by giving a defined apex to the interior of the roof. The main ribs, or principals, are made of channel and plate-iron, and are 6ft. deep, and the total weight of each rib is 54 tons 16cwt., and the cost of each rib was £1,132 4s. The erection of the roof was effected by two large timber stages, each made in three divisions, so that either part could be moved separately. The stages were 40ft. in width, and contained about 25,000 cubic ft. of timber and 80 tons of iron work. The weight of each stage was about 580 tons; and with two ribs on it, the weight on the floor girders, including men and apparatus, was about 650 tons. These stages were designed by the Batterley Company, who were the contractors for the roofing and lower floor.

In the description of the process of erecting, it was stated that the time required for putting up the pieces and rivetting, after the feet were fixed, was six days for each rib; and the last 14 principals were erected in 17 weeks, including delays from weather, &c.

The whole of the ironwork having been fitted at the Butterley Works, it was put together without difficulty. The greatest depression of any rib when the centre was struck was only a quarter of an inch, and the average was 3-16ths of an inch.

The construction of this roof involved the problem of the continuous elastic arch, capable of retaining its own force without any intermediate connections with the tie or any aid from spandrels. With the view of securing ample margin for safety, and to remove all doubt on the question of strength, the arch was designed so as to be capable of bearing an assumed load of 70lb. per square foot in addition to the weight of the principals, with a stress of metal not exceeding 3½ tons per square inch, or a load of 56lb. per square foot with a stress of 3 tons per square inch. The sectional area of the rib is 46 square inches—viz., 23 square inches on the upper and lower flange. The reason for adopting so low a pressure at St. Pancras was that in an arch of this form, and especially under the lateral action of wind, the line of pressure deviates more or less from the centre of gravity of the section. The effect of such deviation is to throw more pressure on one member of the rib than on the other; but the amount of the difference so arising is controlled and modified by the depth and stiffness of the rib in resisting flexure, and also by the extent to which the channel-iron cross-bracing causes the

pressures acting on one member of the rib to be transmitted to the other. Although the roof is independent of the side walls, in so far that it does not rest upon them, yet the weight of the side walls, taken in connection with the manner in which the pedestals or feet of the principals are built in, contributes to the strength of the roof by giving stiffness at the springing.

The roof, as designed, had twenty-four main ribs, and one gable or screen at the northern end. The southern end was intended to terminate against the walls, in the same way as the roofs of the Cannon-street and Charing-cross stations; but the acceptance of Mr. Gilbert Scott's design for the station, offices, and hotel led to this arrangement being departed from. In the original design, the hotel was carried over the upper portion of the southern range of station offices; but as it was feared the steam and smoke of the engines would find entrance into the hotel windows, Mr. Scott planned a second gable and screen for the southern end, so as to separate the passenger station from the hotel buildings. This second screen involved an additional main rib, and, to this extent Mr. Barlow's original design has been departed from. The cost of the roof, as it stands in the finally-settled account, is as follows :—

	£
For the twenty-four main ribs, with foundation bolts, castings for ditto, ornamental spandrils, and moulded bases, &c., ...	27,187
For the covering, including plate-glass, lead-work, purlins, intermediate ribs, wind-ties, gutters, ventilators, gangways, &c.,....	26,296
Total cost of roof, exeluding screens	£53,483
For the north gable	7,375
For the additional main rib, spandrels, &c., at the south end	1,132
For the southern gable	7,375
	£8,507

The total cost of the roof per square of 100ft. superficial, excluding screens, was £31 11s. The additional cost per square of the north screen was £4 7s; and of the extra rib and south screen £5.

On the question of colouring, Mr. Barlow went on to remark, there were two considerations involved, one being the best colouring regarded as a question of ornament, the other being the best colour in respect of its permaneney, having regard to the uses for which the building was intended. Had it not been that the roof in question was for the special purpose of a railway station, Mr. Barlow said he would have endeavoured to select colours solely with a view to the best effect in ornamentation, but he had observed in the roofs of railway stations that the steam from the engines condensed on the metal, especially about rivets and other projecting parts, and that the condensed steam ran down in small streaks, which became stained by the smoke and dust of the station. This effect was observed to take place on the ironwork, but not on the woodwork, the latter not being so good a conductor of heat; and it was therefore thought that however agreeable the appearance might have been rendered in the beginning by light and ornamental colouring, yet that this appearance would have been rapidly destroyed from the causes mentioned, and would require to be maintained at the cost of frequent repainting. It was also found that there was a great diversity of opinion as to what colours should be used, even looking at the question from a purely æsthetical point of view. Considering, on the other hand, the possibility of arriving at a wrong conclusion as to the best artistic effect, and on the other, the probable rapid disfigurement of the work from the causes above referred to, it was ultimately decided to employ French white for the woodwork, and chocolate colour for the whole of the ironwork, which colours so far as experience has extended, appear to possess the quality of endurance as applied to the respective materials of wood and iron.

A vote of thanks to Mr. Barlow for his paper having been proposed by Professor Donaldson, seconded by Mr. C. Barry, both gentlemen expressing their unqualified admiration of this gigantic structure, an animated discussion took place upon various points of principle and details of construction, sustained by Mr. E. I'Anson, Mr. E. Hall, Mr. C. Fowler, Professor Kerr, Mr. Rickman, Mr. G. Aitchison, and Mr. C. F. Hayward. Mr. Barlow ably replied to the numerous questions put him, and to the points raised in the course of the discussion; and the vote of thanks to that gentleman having been passed with great cordiality, the meeting adjourned.

LIMES AND CEMENTS.

LIEUTENANT-COLONEL SCOTT, R.E., delivered his third lecture on limes and cements before the Architectural Association on Monday evening last. In this lecture Colonel Scott took up the question of sand for mortar, a question which, he observed, was a most important one, and one on which there was a great diversity of opinion in the building world, and for many of these opinions there existed very slight grounds. The idea was very general that mortars were improved by the addition of sand. The lecturer said he had no doubt whatever that that idea arose in the first instance from the observation of lime used as stucco. If a very plastic mortar were employed for coating a wall, as it dried it might shrink and show ugly cracks. In proportion as sand was mixed with the plastic material the tendency to crack was got rid of, but the difficulty of making the compost adhere to the wall was augmented; it worked "shorter" as the quantity of sand was increased. The medium required was just between that degree at which the cement would crack from the heat of the sun, and that at which it could not be used by the workman. There was, however, very little foundation for the generally-received opinion as to the action of sand in mortar. Vitruvius gave some reasons why he considered sand to be beneficial. He preferred "three parts of sand, if the sand is fossil" (*i.e.*, pit sand) "with one part of lime; and he says "if the sand is river-sand add two parts of it to one of lime." He went on to say that "the weight of the lime, after calcination, is diminished about one-third by the evaporation of the watery parts; from this it results that the pores, being empty, are better fitted than before to receive the admixture of sand, and to unite strongly with the blocks of stone to form solid masonry." The lecturer remarked that it was hardly necessary to say that there was a great deal that was fanciful in all that. Another attempt to account for the supposed advantage derived from sand was made by Perrault, who endeavoured to prove that Vitruvius was correct, and went on to state what was the opinion of chemists in his day. Speaking of the causticity of lime, Perrault says :—"When this property acts on the sand and on the stones, it brings out of them with time a part of the sulphurous and volatile salts which they contain, and produces between them so strong an adhesion as to form a solid and hard body." On this passage Lieutenant-Colonel Scott observed that sand, almost a pure silica, had neither sulphurous salts nor volatile salts in it, and was therefore quite incapable of being thus acted upon by lime. People assumed, from imperfect observation, that sand was beneficial to mortars, and then sought for fanciful reasons in support of such assumption. Belidor was of opinion that between two and three parts of sand were necessary to one of mortar. Rondelet came to the same conclusion arrived at by Belidor—that it is necessary to mix one part of slacked lime with two parts of river sand, but that if a better lime is used, more sand may be employed. He went further, and said :—"In order in all cases to make a proper mixture, a certain amount of experience is required to judge of the degree of consistence which well-slaked lime and mortar sufficiently mixed should have." He also stated that he had travelled in different parts of the world: "In all the parts of France and Italy through which I have travelled, I have questioned those workmen who appeared most intelligent. I have found that their knowledge reduces itself to a practical knowledge which usage and experience render sufficiently sure." . . . . "A workman, who by a long experience is accustomed to judge if the mortar is fat enough, enough worked, and if it has the consistence it ought to have, is rarely deceived; he beats and mixes the different ingredients of which it is composed until he has hit off the point he aims at," which point, observed the lecturer, is that which the skilful workman found to suit him best. Dr. Higgins had also written upon the subject, but most of his experiments were made upon stuccos, and his experience, therefore, should be looked at from that point of view. He made all his experiments by weight, and prescribed that no more than one part of lime to seven of coarse sand ought to be used in mortar to dry quickly; and less lime might not be used, because it did not render the mass sufficiently plastic for building or incrustation. The lecturer accounted for the discrepancy between Higgins's and Rondelet's statements in this way: Dr. Higgins, although concluding the proportions named (about 3 to 1 by measure) to be the best for building purposes generally, arrived at them by experiments made with reference to stuccoing; for which purpose freedom from shrinkage was a more valuable property than freedom in working. He decided, in reality, on the most plastic composition which did not crack in drying. Smeaton went a step further, and gave some sufficient reasons why sand should be used. He thought sand made a harder mortar, thus improving its quality while adding to its quantity. He says :—"The experience of ages has shown that a considerable quantity of sand and other matter may be introduced with advantage in the making of mortar, but the proportion has never been agreed in; yet from common experience it appears that there is scarcely any lime but what, if well-burnt and beaten, a load or measure of lime will take two loads or measures of sand." Still pursuing the subject, to see how far the admixture of sand with lime could be carried, Smeaton further says :—"It appeared that even yet a greater proportion of sand could be introduced, but to bring it to a proper consistency and toughness, so as to be a good cement to large stones, I found it needed so much more beating that the labour became in most cases of more value than the saving of materials." On another point he says :—"As the lime will receive the most sand in that way" (*i.e.*, if the sand is coarse), "without losing its plasticity, it will of course make the hardest and firmest mortar." The lecturer remarked that this idea of there being some connection between the toughness of the mortar when wet and its hardness when well set ran through the writings of all the authorities he quoted. Vicat, writing on the question of sand, drew equally nice distinctions with those which had previously been quoted with reference to the various methods of slaking between the composition that should be given to mortars according as they are made from fat or hydraulic limes—as they are slaked by the ordinary method, by the method of immersion, or by the spontaneous action of the atmosphere—and according as they are intended to exposure to weather, to damp, or vicissitudes of heat and cold. He says :—"The addition of sand is injurious to rich limes, very serviceable to the hydraulic and eminently hydraulic limes, and is neither beneficial nor injurious to the intermediate kinds." Now it was generally believed, observed the lecturer, that if any lime was benefitted by the addition of sand, it was a pure fat lime, yet Vicat said that rich limes were injured by their admixture with sand. Colonel Raucourt de Charleville came to the conclusion that if the sand was harder than the cement, the more of it there was in a mortar the better and harder that mortar would be; but he objected to smooth sand. In every respect he drew distinctions (similar to those made by Vicat) between the capacities of different descriptions of lime for being benefitted by the addition of sand. Pasley did not get over this tendency of the world generally to stick to the long-received opinion as to the benefit which limes received from their mixture with sand. "We found," he says, "by repeated experiments at Chatham, that one cubic foot of Halling lime weighed nearly the same when fresh from the kiln; and, by the gradual addition of water, that it dilated to the same increased bulk in the state of quick-lime powder; but when worked up into mortar, not too short for use, that it would not bear quite so large a proportion of sand as the common chalk lime had done." Hence, he concluded that, "it follows that the hydraulic limes ought not to admit of so much sand as chalk, but that they will bear more than cement without being injured." Of course in this case Pasley was speaking of Roman cement, for at the time he wrote Portland cement had not been invented. In another part of his work Pasley wrote of the proportions of lime and sand that made mortar fit for use, and of mortar that could not have borne more sand without becoming "short." After making some experiments on the point, he writes :—"Contrary to our former opinion, which was chiefly derived from the apparent shortness of the mortar made from three measures of sand

to one of lime," it had been so far disproved as to show "that, although a mixture of two of sand to one of blue lias still appears to make the best mortar, yet 3 to 1 does not spoil it, as we formerly believed." In Pasley's mind there existed the old notion as to there being some necessary connection between plasticity in working and hardness in setting. Treussart (who had made, perhaps, more careful experiments on the subject than any other man) was also possessed with the same idea, and only gave up the notion with very great difficulty indeed. He says, with reference to the first set of experiments which he gave:—"I regret not being prepared for this superiority of the hydrate [he means by this the lime without sand] over mortars, but I was far from expecting it, otherwise, after having made the experiments with the limes alone, I should have made mortars by adding successively ¼, ½, ¾, &c,, of sand, so as to judge better of the effect of sand; but it was only on breaking the mortars at the end of the year that I could know the effect, and I have often on such occasions obtained results that surprised me." In remarking on the results of some experiments made with a view of determining the effect of sand, he stated that the best result followed with one part of lime in paste to one of sand; but he says he did not anticipate that there might be hydraulic limes which would bear a still smaller quantity of sand, or he should have made trials with other limes, "in order to know if the sand added in the composition of mortars always, or only with some peculiar limes, diminished the resistance of hydrates." He was very unwilling indeed to give up the idea that sand strengthened limes until his own experiments obliged him to do so. Belidor, Rondelet, and Pasley, all thought that hydraulic limes would not stand so much sand as the fat limes would; while Vicat, as he thought, experimentally proved that fat limes stood the least sand. The common opinion in the present day, remarked the lecturer, was that fat or pure limes would take the most sand—and in one sense they undoubtedly would do so. Vicat and Raucourt were of opinion that fat limes were injured by sand; Pasley thought that cements were injured by sand; Raucourt finally came to the conclusion that all limes were injured by sand; and experiments made of late years by Colonel Totten, in America, have borne out that view.

Before coming to any final conclusion on the question as to where sand might be advantageous or otherwise, the lecturer said it would be well to take into consideration the facts which bore upon the hardening of mortar. It was very possible, he remarked that, without any chemical action at all, the application of so plastic a material as lime-paste between the grains of sand would result in securing considerable mechanical adhesion. Then there was considerable cohesion amongst the particles of lime themselves. Then there was the possibility that (owing to the use of sand) in making a fracture across a mortar-joint, the line of fracture might be made to take a longer course than would be anticipated—there might be a sort of interlacing between the particles of sand, something like the bond in brickwork. Because sand did not always strengthen mortar, but often the reverse, it was not to be supposed, however, that under no circumstances could increased strength be given by the use of sand. If two bricks were cemented together, the one over the other, the addition of sand to the mortar might possibly give greater strength, because as limes set in great measure by the action of the carbonic acid gas of the atmosphere, the sand might, in such a case, particularly if coarse-grained, give greater facility for the gas to get into the pores. But this would not apply to cases in which the mortar was placed well in the interior of the work, where the carbonic acid gas could not get to it. In such cases, where the material was such as would never of itself get very hard, the cohesion must be very large. Wherever experiments had been made under such circumstances, the sand had resulted in decreasing instead of increasing the strength of the mortar. As to the nature of the sand to be used, there was very conflicting evidence. Vitruvius preferred pit-sand fresh dug; Belidor preferred river-sand; Perrault thought that the white sand was the best; Belidor said that colour had nothing to do with it; Rondelet came to the conclusion that the best sands were neither sharp nor smooth, and that those deep in colour were better than the yellow sands. The only point on which they all agreed was that the sand should be clean, and this point was, as practice showed, of the very utmost importance. A very small quantity of clay, indeed, was quite sufficient to make the mortar moulder; from one-seventh to one-eighth would make the frost attack the mortar. All clayey or loamy sand should, therefore, be very carefully washed. The authors quoted did not agree as to the action of sea sand. Most of them were of opinion that it made bad mortar, though some said that it gave good results. Trenssart thought that, on the whole, a fine sand was better than a coarse sand. Vicat gave a great many results of experiments tending to show that various sorts of limes and cements required sand of various degrees of fineness or coarseness; but inasmuch as each author invariably contradicted his predecessor, the lecturer thought it might be safely assumed that it was pretty much a matter of indifference what the nature of the sand might be so far as regarded the size of its grains. Sea-sand, as he had before said, was proscribed by most authors; but some particular cases were mentioned by Alberti, Davy, and others, in which benefit accrued from its use. Smeaton used it in the construction of the Eddystone Lighthouse, and found that the lime was not injured by it. Partington went at great length into the action of the various kinds of water used in making mortar—spring, rain, river and sea. Colonel Totten came to the conclusion that limes were weakened by the use of sea-sand. Endeavouring to reconcile the conflicting opinions on this point, the lecturer remarked that if sea-sand were employed for plastering it always, as was well known, kept the work damp. This was caused by the chloride of sodium of the sea-water, which combining with the lime, produced chloride of calcium; some of the soda was set free, and the chloride of calcium, getting a little dry during hot weather, when a damp day came it invariably attracted fresh moisture from the atmosphere, and always kept the work wet. If sea-water or salt sand, therefore, was used in conjunction with pure limes, the mortar resulting would never get dry. With hydraulic limes, however, the case was different, for mortar made with such limes must be kept moist to ensure the formation of the silicates and the hardening to the requisite degree. Therefore one man experimenting with fat limes would come to the conclusion (and very properly so) that sea-sand was injurious for use in compounding mortar; while the one who experimented with hydraulic limes would conclude (quite correctly) that sea-water was beneficial. But sea-water should never be used for plastering.

The lecturer next proceeded to speak of other substances which were sometimes mixed with sand, remarking that in this country, formerly, puzzolano and trass were largely used to improve the setting properties of limes. Both these substances resulted from volcanic action. Trass contained 49 per cent of silica, and nearly 4 per cent. of potash and soda. Puzzolano had rather a smaller proportion of silica (44 per cent.), but more potash and soda (5½ per cent.). Each substance also contained a little lime and some oxide of iron and alumina. When these substances were heated together with silicic acid the tendency to form silicates was very much increased. In trass and puzzolano the baking action required to bring about that condition had been done by Nature; each substance afforded in itself a kind of cement to begin with. The invention of Portland cement, however, had caused those materials to go out of fashion, as the result obtained by their use was not so quick in action as that got by Portland cement, nor, indeed, was it so perfect.

In conclusion, the lecturer described the various methods of lime-burning, and the kilns used, but as this part of the lecture involved repeated reference to the diagrams on the wall, we cannot give it *in extenso*. Nor, in fact, is it necessary that we should do so, as the subject was not long since treated of very fully in these pages by Mr. Gilbert R. Redgrave. Suffice it to say, therefore, that of the three principal forms of kiln he mentioned, the tunnel kiln, the flare kiln, and the so-called American kiln, the lecturer preferred the last named, somewhat modified, as in use at Rudersdorff and elsewhere.

The fourth and last of this interesting and valuable course of lectures will take place on Monday evening next.

The Braintree Independent chapel is about to be greatly altered and added to, at a cost of upwards of £1,000.

The Austrian Government has determined not to abandon the proposed International Exhibition at Vienna in 1873.

THE GRAND ORGAN IN THE TOWN-HALL, LEEDS.

We give this week the elevation of the organ erected by Messrs. Gray and Davison in the Town-hall, Leeds, and a few particulars of it may not be without interest to many of our readers, as it is one of the largest and most complete instruments in the world. It contains no less than six distinct organs, acted on by four manual claviers, the compass of each being from CC to C in altissimo, 61 notes; besides the pedal organ, which extends from CCC to F, 30 notes, 117 stops, as well as 17 combination and other pedals for various movements, and 6,500 pipes, viz.:—

Solo Organ	506	Pipes.
Swell Organ.....	1440	,,
Front Great Organ	1159	,,
Back Great Organ	1152	,,
Choir Organ	1123	,,
Echo Organ	520	,,
Pedal Organ.....	600	,,
Total	6500	,,

The great organ consists of two complete and distinct organs of different powers and qualities; and the echo organ constitutes a complete little organ of six stops, the pipes of which are of small scale and voiced on an extremely light pressure of wind; they are placed within the box of the swell organ, and can be played by either the swell or choir clavier.

The mechanism, pipes, &c., are placed on four floors. On the first, or ground floor (which is the top of the orchestra, and 16ft. from the floor of the hall), is arranged the greater part of the mechanism; on the second floor, are arranged the the great and pedal organs; on the third floor are the swell, echo, and choir organs; and on the fourth floor the solo organ, in two separate boxes. The pipes are distributed over several windchests, so that the tuner finds no obstacle in getting at any part of the organ.

The difficulty always experienced of supplying organs of the largest class with an adequate supply of wind has in this instance been overcome by the employment of hydraulic engines; five of these most simple machines are attached to a like number of bellows placed in the basement of the building, and the wind-supply thus procured is thence distributed to the various departments of the instrument through the intervention of twenty-seven reservoirs, so weighted as to give the desired varieties of pressure. The united power of these hydraulic engines—equal to eight-horse power—is capable of supplying one hundred cubic feet of air per second.

The pneumatic action is applied to all the claviers, so that the touch, which would otherwise be very heavy on so large an organ, is extremely light.

The front of the organ was designed by Mr. Cuthbert Broderick, the architect of the Town-hall. The pipes are illuminated in gold and colours by Mr. Crace, who also carried out the decoration of the hall. The non-musical reader may be interested to learn that the largest of the metal pipes in front, standing on the first tower on the right of the claviers, is 36ft. in length, with an internal diameter of 21in.; while among its 6,500 pipes is found every variety of dimension, from the largest, just mentioned, to the smallest, the length of which is but three quarters of an inch, with a diameter scarcely exceeding that of a straw.

The organ occupies the north end of the hall; it is upwards of 50ft. high, about 47ft. in width, and 25ft. deep in the centre, and weighs nearly 70 tons.

The total cost, including the case and hydraulic engines, was about £6,000.

Cambridge School of Art.—Lord Houghton on Tuesday week distributed the prizes to the pupils of this School. In the course of his address his lordship referred to the recent establishment of a Professorship of Fine Arts in connection with the University, and which, he said, was not established a day too soon. The nobility and gentry of the present day did not study and appreciate art like their ancestors of a century back, and he recommended the authorities of the University to try and foster an appreciation of art. Cambridge was singularly fortunate, he observed, in the grand incentive to the study of art which existed in the magnificent buildings of the several colleges.

DECORATIVE PROCESSES.

By "AN EXPERIENCED WORKMAN."

EMBOSSED AND FIGURED GLASS.

EMBOSSED glass, as a means of decoration, has been practised for a great number of years, but it has only been within the last thirty or forty years that its usefulness as a decorative agent has been fully developed and recognised. The quiet and unobtrusive contrast between the dead or ground glass and the transparent ornament, which has apparently a slight relief, enables this kind of work to be used with all styles of architecture—Gothic, Italian, Greek—and in all and every situation where ornamental glass is used—vestibule doors, staircase windows, entrance doors to banks and public institutions of every kind. Letters and inscriptions may be written in combination with ornament to direct or instruct. It is also useful as a permanent blind to the lower parts of office windows in commercial or municipal buildings, and for screens. Beautiful effects may also be produced by gilding and silvering in combination with embossing, and by the introduction of coloured foils and imitation gems of coloured glass, cut with numerous facets: these are fastened underneath, or at the back of the glass, in spaces left purposely in the design. Messrs. Jennings and Bettinge, of Birmingham, have brought this portion of the art to great perfection, and many specimens of it were displayed by them at the Great International Exhibitions of 1851 and 1862, some of them being perfect gems of art. Opaque glass panels for the doors of cheffoniers, sideboards, wardrobes, the saloons of steam-vessels, bookcases, &c., may be beautifully decorated by being embossed and then gilt and coloured. The embossed ornament may be gilt, and the plain part ground or obscured in the manner hereinafter mentioned. This style has a very quiet and chaste effect, and the obscuring forms a beautiful background in contrast with the gold or silver. Finger-plates for doors are very nice done in this style. Many years ago, when plate glass was limited in size to small plates, and the old-fashioned chimney or pier glasses having broad bevelled edges to them were in vogue, embossed and cut ornament was much used for borders and corners, generally done in the Italian style, many of them of very beautiful design; they were afterwards silvered and gilt. Examples of these old mirrors may now and then be seen in some of our old country mansions and the old curiosity shops. Many useful lessons may be derived from the study of these old works of art. The use of embossed glass in the present day is very extensive. There is scarcely a warehouse, a manufacturing establishment, a shipping-office, or public building of any kind throughout our great towns and cities, in which embossed or ornamental glass in some shape is not used; and there is no style of glass ornamentation so well adapted for the purpose, inasmuch as we thus get ornamental and emblematical designs and inscriptions without interfering with the passage of light, which is, of course, the primary object and use of glass, and to which all else should be subordinate. There are, of course, many uses to which embossed glass is put besides those before named, such as public-house and gin-shop signs, glass facias for shop fronts, &c., &c. These, as a rule, are executed by the sign writer. Ornament for embossing will require, in the first place, to be designed in strict accordance with the style of the architecture of the building of which it forms a part. How often do we see the ornamental glass of a vestibule door in which the ornament will probably be in the Gothic style, whilst the door of which it forms a part is Italian or Greek, and *vice versa*. This does not always arise from want of skill in design or execution; but as much of this work is both designed and executed by artists and workmen regularly employed in the various stained glass works, who are most of their time engaged upon the stock Gothic canopy work for fitting into any and every stained window manufactured, as a consequence these men acquire a certain amount of Gothicism, if we may so speak, which they stamp upon every kind of ornament they do so that if they attempt to design an ornament in any other style they cannot help but impart a Gothic character to it; and it is a singular fact that men who, as it were, continually run in one groove, are seldom able to break away from the fetters they thus insensibly weave around themselves, and so we get those numerous incongruous examples of ornament of which so many may be seen not only in embossed glass, but also in other classes of ornamental art. Again, these mistakes in style and in adaptation of design to the purpose to which they are applied will and do arise from ignorance, narrowness of idea, and from inexperience. Ornament intended to be embossed upon glass should be designed expressly for that purpose, having always in consideration the peculiarities and capabilities of the material upon which the ornament has to be formed, having regard also to the methods of working. It should never be forgotten that the light has to pass through the ornament, and that this passage of light is the primary condition of the position and circumstances of the glass; it is so placed for the transmission of light, and therefore anything that interferes with that condition is a defect. The eye should be able to rest upon the ornamented glass without feeling oppressed or confused, and except this be the case no ornament can be appropriate or suited to the purpose. Small and intricate ornament cut up with fine lines has a disturbing effect on the eye, besides being unsuited to the material. It is true that finely-etched ornament may be correctly executed by this method, but when used for architectural decoration the design should be treated with breadth and freedom; the simpler the ornament the better suited it will be for the purpose. Conventional leaves with interlaced lines or strap ornament is well adapted for embossing, and it should always be borne in mind that flat ornament is best suited to the material from every point of view, best adapted for execution, most suitable for the transmission of light, and looks best when done. Cross hatching is used for shading on embossed ornament, but we think this an error, except it is used in dissecting coats of arms and emblematical designs; in these cases we can scarcely do without; but simple lines are best for cutting up and defining ornament, and the fewer there are of them the better. The manipulative process of embossing glass is carried out as follows:—Hydrofluoric acid has the peculiar property of dissolving or separating the component parts of ordinary glass; and this acid is the active agent used for embossing. It is needless here, and would serve no purpose, to describe the method of manufacturing this acid, simply because it is a common article of commerce, manufactured by practical chemists, and supplied by any druggist or oil and colourman, and therefore the student need not occupy his time in endeavouring to make what he can purchase at a tenth of the cost he would incur in making it for himself. By the way, we would remark that a great part of what would otherwise be really practical works are occupied with useless descriptions of the methods of making articles which can be bought much cheaper, and a great deal better, than any amateur can possibly make them, thus leading the student to waste valuable time which might be much better employed. All branches of the decorative art were at one time a much more laborious and difficult study than they now are: one reason being that the secrets of the manufacture of various chemical substances and mixtures used in the arts were the exclusive property of the masters of this or that particular trade or profession; and these secrets were handed down from master to pupil, and from father to son, as most valuable possessions, to be guarded and preserved with most jealous care and secrecy. This state of things is now changed to a very great extent. It is true that there are in some manufactures trade secrets which are still guarded with as much care as in the olden time; notably in the manufacture of varnishes, where each manufacturer has some special method or mixture he calls exclusively his own, and the knowledge of which he keeps to himself. But of late years so much study and scientific knowledge has been brought to bear, and so many master-minds have devoted their whole time and energies to the invention and discovery of the secrets of chemical science, that we may almost conclude that the days of trade secrets have passed away. Manufacturing chemists now supply all the necessary pigments, whether artificial or natural, and those of the best; chemicals of the best and purest kinds are produced in quantities and at prices with which no amateur can compete. We shall, therefore, confine ourselves strictly to the simple manipulative process of embossing.

Embossing on glass means simply the eating out, or cutting of a sunk or incised pattern into the body of the glass. This may be done by cutting with the glass-cutters wheel and sand and water, or by burning or eating the glass away, or rather dissolving the glass. Glass cutting or engraving by the wheel and sand is not applicable to large plates or squares of glass, on account of the difficulty of handling, and the danger of breaking; and the only other process yet discovered is this method of dissolving glass by the aid of hydrofluoric acid. This acid is, we believe, the only direct agent known having the properties of dissolving glass. It is a colourless liquid, produced by a chemical combination of sulphuric acid and fluor-spar; it requires very great care in handling. The fumes arising from it when exposed to the action of the atmosphere are highly deleterious, and as it destroys all bottles of glass and earthenware, it is necessary to keep it in metal or gutta-percha bottles. We would here specially caution the workmen to avoid breathing or inhaling the vapour which arises from the acid when it is put upon the glass in working with it, as its action is very injurious, causing ulceration of the lining of the thorax and the lining of the mouth and nostrils. Fluoric acid varies much in strength when purchased at various times, and from different makers; any respectable dealer in drugs will supply it at about 1s. 6d. per pound, but, of course, it may be had at a much cheaper rate from the wholesale houses. The acid is scarcely ever used in its full strength as sold, and before using will require to be diluted with water. We can give no rule of strength to be used, not only because the acid itself varies in strength when it comes from the chemist, but the glass also varies so much in hardness that one piece of glass will take twice or thrice the time to emboss that another plate will take. We cannot account for this difference in the glass, except it be in the difference in the annealing process; even in cutting the glass with the diamond this difference in hardness will be readily and continually felt or experienced; so that it is only by practical experience in the act of manipulating the acid that the workman can regulate its strength. Embossing may be done upon two kinds of glass: plain glass upon which the design may be embossed, and the plain parts ground or obscured with emery or fine sand in the manner hereinafter described—the design will then have the appearance of a bright and transparent ornament on a semi-opaque white ground; the next kind of glass suitable for embossing is the overlaid, or flashed glass, that is glass which is coated on one side with

a thin veneer of coloured glass. This glass is principally made of what is called table glass—the oldest form in which window-glass was made. The glassblower first takes up on the end of the blow-pipe a portion of white glass in a liquid state, he then dips this into a pot containing coloured glass, also in a fluid state; the two are then blown and manipulated until they expand into a circular sheet of glass, having the blow-pipe for a centre, and the coloured glass, technically called pot-metal, forms a thin coating upon the outside of the sheet. The centre, which is attached to the blow-pipe, forms what is commonly called a bull's-eye, which were often used for glazing in cottage windows before the invention of sheet glass. Sheet glass may also be flashed or coated with coloured glass; but sheet glass is blown in a different manner to the table glass, but is not so clear in consequence of the flattening process it has to undergo in the annealing. The metal is taken up on the end of the blow-pipe in the same manner as before described, but in larger quantities. The glassblower stands upon a stage exactly similar to a saw pit, with planks running from the mouth of the kiln holding the melted glass. Underneath the planks is a pit 7ft. or 8ft. deep. The workman stands upon one of these planks, and holding the blow-pipe blows down the pipe and swings the metal at the same time. By alternate swinging and blowing the metal begins to stretch out into an elongated cylinder, the centrifugal force causes the glass to stretch, while the blowing forces it into a cylindrical form. Some of these cylinders are 5ft. long, with a diameter of 12in., 14in., and in some cases 16in. Glass shades are thus blown, but with this difference, that while the glass is in a soft state the cylinder is pressed between two pieces of wood, which flattens the sides, and gives these shades their semi-oval form. These cylinders are then cut level round, the bottoms and tops with a glazier's diamond fixed upon wheels; they are then cut down one side and laid in the annealing kiln, and when they acquire a sufficient heat are flattened by being rubbed with a thick clump of wood fastened to the end of a long pole. Now this flashed or coloured glass may be embossed by eating away the coating of coloured glass until we come upon the under coating of white glass, and the effect produced is of a white transparent ornament upon a coloured ground; or the two may be reversed, the ornament or letters remaining coloured and the ground-work be white. It will be evident that there is a wide field for the use of this kind of glass for bordering of staircase windows, vestibule doors, lamp-glasses, &c. A very harmonious and chaste contrast is gained by using this coloured glass in combination with the plain or white embossed glass, and also in conjunction with gold and silver leaf, of which we shall speak further on. In addition to the fluoric acid for embossing, we require to use the best Brunswick black, some Burgundy pitch and white wax. It is necessary to the perfect success of the operation that the Brunswick black should be of the best, and free from admixture with any foreign matter. Too much care cannot be exercised or pains taken to avoid any dust or particles of grit being mixed with it in working. The Burgundy pitch and white wax must be mixed together by heat, sufficient wax being added to the pitch to keep it in a plastic state, and of the consistency of putty, used while warm. This is called walling wax; of its use we shall speak hereafter. Black japan is sometimes used instead of Brunswick black, but we prefer the latter, inasmuch as it resists the acid much better, and is more easily cleaned off the glass when done with, and is also less brittle when dry than the black japan.

(To be continued.)

Byfield church, Ongar, has just received an addition in the shape of an eight-day turret clock by Benson.

SELECTED DESIGN, LEEDS UNION INFIRMARY.

WE gave last week an elevation of this design, and now present a perspective view of the building. Mr. Walker, from his description of the design, appears to have paid special attention to the important question of ventilation and heating, which he purposes to effect by the hot air system. He would carry a single line of steam piping round each ward, and box it in with wood, in order to form an air-flue about the pipes. To this flue, air would be conveyed from a common supply trunk, under the floor of the lowest ward, by means of intermediate flues in the walls; and admission of the air to the wards, after passing over and for some little distance along the steam piping, would be provided for by openings in the wood-work at regular intervals. No air could thus enter the ward without having received some degree of heat from contact with the hot pipes, and the temperature of the room would depend on the degree of heat applied to the pipes, and on the speed with which air is allowed to pass over them. As the air is admitted to the ward, the warmth it has gained from the pipes will cause it to ascend, and carry up with it all atmosphere exhaled by patients, until it reaches the ceiling, near to which a number of outlets are provided, all communicating by separate flues with a common trunk in the roof, which discharges the whole spent atmosphere of each pavilion into the ventilator placed over the conveniences.

The supply and discharge-pipes would be of such dimensions as will admit of the air being renewed imperceptibly, each ward being furnished with a supply of 12,007 cubic inches of air per minute for each patient, travelling at a velocity of one foot per second, being about thirty times the amount actually respired. The heat of the hot pipes will ordinarily cause a sufficient air-current to ventilate completely the wards; and, whenever additional ventilation is needed, it will only be necessary to expedite the current by the use of a small fan fixed at the mouth of the supply trunk, which can be worked either by the steam from the boiler used to supply the pipes, or by water pressure obtained from the cold water tank. The steam supply for heating would also serve, if necessary, for working the hoist.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

DR. G. G. ZERFFI delivered the nineteenth lecture of this course on Tuesday afternoon last, at South Kensington. Having considered the productions of the school of Ægina in his previous lecture, he now turned to those of the school of Attica. Referring to the statue of Penelope, now in the Vatican at Rome, he said that in that figure were seen the first attempts of Attic art to represent a psychological idea. The Hestia (Vesta) in the Torlonia Museum at Rome, and an excellent marble relief from a Puteal near Corinth, in which Herakles was represented as about to be married to Hebe, were works of the same kind. The latter was, the lecturer remarked, undoubtedly one of the very best specimens of the end of the first period. He next proceeded to consider the artists of the transition stage, which eventually led up to Phidias and his school. The three names Kalamis, Pythagoras, and Myron represented a steady and gradual improvement in Greek art. Relief had been cultivated, and not only single statues, but whole groups had been detached from the supporting walls and had formed independent works of art. The heroes, unlike many of the divinities, had not been delineated according to general patterns. A keen study of the human form could alone have produced them, and the grouping showed the powerful influence of the creative force of the artist. We might trace during this period the struggle of the artists to free themselves from fixed rules. We had before us different types of the divinities; but these, though bearing evidences of the artist's individual conception, were still fettered by hierarchical prejudices. The attributes of the gods were too prominent—the thunderbolt of Zeus, the caduceus or herald's staff of Hermes, the bow of Apollo, and the club of Hercules appeared to have been considered more important than the idea of the abstract powers of those divinities. These attributes were not yet the incarnations of sublime thoughts on the nature of the gods, but merely outward signs of their material power. With regard to the works of the three artists before named, Dr. Zerffi observed that a copy of a Hermes bearing a ram on his shoulders, the original of which was by Kalamis, was in the possession of Lord Pembroke. In this work the head of the ram was admirably executed, but the outlines of the body, which had a stiff naturalness, were too sharp. This artist was especially distinguished for his representations of horses. Pythagoras was celebrated as having been the first to introduce harmony in the proportions of the body; this was particularly to be observed in a statue of Philoktet, which represented the archer of that name, who, having been bitten in the heel by a serpent, was still endeavouring to drag himself along in order to be at his post and assist in the Siege of Troy. This painful moment had been seized by the artist and rendered with such power that the beholder might almost be said to feel a thrill of pain pass through his own body. Of the works of Myron, we had the Marsyas, at the Lateran, and the Diskobolus, or disk-thrower. In describing the latter, the lecturer compared it with a modern statue by Roth, of Münich, and observed that in looking at the two, side by side, the great difference between idealism and so-called naturalism was clearly to be perceived. In the one, the moment before action was represented (the figure being about to throw the disk); in the other the action had already taken place, and the figure was in repose, holding a heavy weight suspended over its head. The latter was without doubt a masterpiece as an anatomical study—every sinew, every muscle, being correctly represented—but as a work of art it failed, being in no way really beautiful. In the production of Myron, on the other hand, the muscles were softened down and rounded, and the power of the artist was directed to beautifying by means of his intellectual force those forms which might be coarse in Nature. The lecturer also refered to the famous bronze cow by this artist, of which he remarked that all traces had been lost, though from what could be gathered from the works of different authors it must have been exceedingly lifelike. In this second period of the development of Greek art, therefore, Kalamis had been the representative of a clear and definite feeling; Pythagoras represented naturalness in the reproduction of forms which reached perfection; while Myron was the representative of the first dawn of idealisation. Myron's idealisation had, however, been confined to bodily forces, as the faces of his statues lacked a higher inspiration. The acme of Greek sculpture was reached by his contemporary, Phidias, who might justly be called the Shakespeare of his time. Phidias in Greece, like Shakespeare in England, lived at a period when his country was enjoying the brightest and most glorious moment of her national existence. He begun to work at the time when youthful Greece had performed her great deeds of valour—when she had checked the encroachments of the Asiatic barbarians, and had secured on the battle-field of Marathon, and at Salamis and Platæa, the victory of Beauty, Science, and Art. In the days of Shakespeare a Queen Elizabeth ruled in England; and Greece in the time of Phidias was swayed by men like Kimon, Thermistokles, and Pericles. Phidias, in accordance with the Greek element, had produced outward forms in perfection, and endowed them with his immortal spirit; Shakespeare, in accordance with Christian ideas, had given us immortal characters, conceived in spirit and expressed in abstract signs, which stepped from the printed leaves and stood firm as the marble conceptions of Phidias before us. The small Greece of Pericles, like the small England of Shakespeare, had begun to develope with surprising rapidity—the one cultivating architecture, sculpture, and science, and the other poetry, industry, and commerce. By the one the Persians had been repulsed, their despotism broken; by the other the Invincible Armada had been scattered, and the spiritual despotism of the Middle Ages destroyed. Greece had produced a whole phalanx of noble warriors; England had reared a whole race of sea-heroes. Both had proved that periods of renewed political activity and animated national feeling produced great men in countries in which there was a genuine vitality. The vitality of Greece produced Pericles in politics, and Phidias in sculpture and architecture. Athens was to have been made the abode of the gods, the temple of the Muses, and the centre of learning and art. Phidias (who was born about 500 B.C.), was the son of Charmides, of Athens, and was the pupil of Hegias and Ageladas. His two most

celebrated works were the Zeus at Olympia (432 B.C.), and the Athene of the Parthenon (437 B.C.) The Athene which he produced was 40ft. high, composed of gold and ivory laid over a wooden form. Simplicity, peaceful power, benevolent protection, and victorious self-reliance were expressed in this work. It was a characteristic fact that in Greece there were many mythical heroes, but very few deifications of mere historical soldiers. There were statues without number of those who distinguished themselves in poetry or art, or who had gained prizes as wrestlers or runners, but mere destruction was not so respected. Phidias especially succeeded in giving a concrete form to the abstract conception of the, divinity as far as was possible. His works were very numerous; in addition to the statues of Athene and Zeus mentioned, there were thirteen others, of which six were of Athene (one of them being in bronze and 70ft. high), one of Apollo, one of Hermes (marble), three Aphrodites (two marble and one gold and ivory), one Mother of the Gods (material unknown), and an Æsculapius in gold and ivory. Of sacrificial statues, the most celebrated was a group of thirteen figures in bronze, in commemoration of the Battle of Marathon. The only historical figure in this group was that of Miltiades, the twelve others surrounding him having been mythical heroes. Phidias was no less skilled in chiselled works of the smallest kind. According to Martial, he made fishes, bees, flies, and a cicada. Of all these, however, none remained. His Zeus was struck by lightning in the time of Cæsar; and during the reign of Theodosius II. (A.D. 408), the Temple of Olympia was destroyed by fire, and with it the great masterpiece perished. The Athene was lost, it was said, in the tenth century of our era, but had, no doubt, been destroyed before that date. All that remained of Phidias's works were some of his architectural sculptures, which, at least, served to prove the great master's genius. Amongst these were—The metopes of the Temple of Theseus, eighteen in number, ten of which, from the eastern side, represented the deeds of Herakles, and eight, from the north and south, those of Theseus himself. Of the frieze (representing an heroic combat under the guidance of the gods), there were splendid casts in the British Museum. The metopes, the frieze of the cella, the statues from the pediment of the Parthenon, and other works by this great master having been described in detail, Dr. Zerffi concluded by observing that neither Phidias, nor the school he founded, was sensational, but did justice to poetry in exquisite forms, finished with great care and technical knowledge. Alkemenes and Phidias had had to produce colossal figures of Athene; and that of Alkemenes whilst still on the ground obtained the prize, that of Phidias appearing out of proportion and coarse. When, however, the statues came to be raised on their lofty pedestals the critics had to revoke their judgment—that of Phidias appearing perfect, whilst that of Alkemenes had lost all its refined and detailed charms. From this it was evident that perspective had been studied with the greatest attention by Phidias, and it was much to be regretted that the same could not be said of more modern sculptors. The great merit of Phidias, however, was idealisation; with him the study of anatomy was not degraded to a coarse naturalism, but had served as a mere basis—as a framework or mould into which he had poured his sublime conceptions of the forms of mankind, so as to reproduce their spiritual essence in matter. In this direction he was followed and almost rivalled by Polycletus of Argos.

A NEW ROAD MATERIAL.

ASPHALTE, granite, and macadam have all been temporarily superseded as road materials in Kennington lately by churchyard mould and bones. A new roadway is being made, and last week one of the sanitary inspectors who visited the spot found that several loads of earth, intermingled with skulls, bones, and portions of coffins had been brought to the place for the purpose of making up the ground. A number of boys assembled and awaited the arrival of the carts, and upon the load being deposited they set to work collecting the human remains, which they afterwards sold. Some thirty to forty cartloads appear to have been brought from an old burial ground which is being disturbed for the purpose of making additions to the National Gallery, which it adjoins. The Secretary of State had *directed* the remains to be collected and re-interred; but it was far less trouble to all concerned to let things take their course, and allow the bones to be carted off to be used as road materials, or to find their way to the rag-shop through the agency of the thrifty, but rather unscrupulous, juvenile population of Kennington. The burying-ground referred to appears to have been used as a plague-pit. This fact is especially worth remembering by the inhabitants of S. Martin's-in-the-fields and Kempsford-road. Seriously, ought the contractor, whose carelessness, or the carelessness of whose men, is responsible for this dangerous outrage on good-feeling, to escape with a gentle magisterial reprimand?

GUILDS FOR ART AND ARTISANS.*

WE thoroughly agree with the author of this pamphlet, that "there is no greater sign of the dismembership of society than the unsystematised and spasmodic efforts that are now made to revive art." There are very few who deny the decay of artistic feeling—almost as few who can agree as to the method of its regeneration, or who really have made up their minds what it is they wish to regenerate. Mr. Fry has one strong claim on our attention. He is at least practical and talks common sense. His propositions are simple and his conclusions have a business air about them. He lays down the axiom that, to reproduce the art work of Mediæval times, we must first reproduce the system which gave it birth. First of all he recognises the existence of a healthier and more vigorous tone about the demand and supply of the Middle Ages. The customer knew what he wanted and went for it to a practical workman, and betwixt them no "middle man" intervened. The "master mason" took the idea of the work from the employer, and, occupying the places now held by the architect, the builder, and the clerk of works, devoted his undivided attention to the work during its progress, and personally superintended all engaged in it. As a practical way of effecting such a change on the present system, Mr. Fry suggests that architects should leave their offices, corporate good artisans with whom they are personally acquainted into guilds, and execute their own designs themselves *one at a time*. What sort of a reply, we wonder, would be made to this by Mr. Scott, who turns out his churches by the score, like a manufacturer of chairs and tables, and with about as much personal superintendence!

The "corporate guilds" would consist, according to Mr. Fry, of members all personally known to each other. Strikes and lockouts would be avoided, because the connection between masters and men would cease to be wholly of a mercenary character, as it is at present. They would no longer be merely machines, but each possessing the privilege of a voice in the work, subject only to the control of his chief, they would soon cultivate an *esprit de corps*, which would prove a potent power for good in improving the work done.

From the establishment of such guilds Mr. Fry candidly admits he expects no immediate great improvement. "But the right track would have been found which has been known to lead to the true goal, and, by steadily pursuing it, in course of time one might hope to arrive at the same termination—to a style of architecture as pure, as genuine, and as essentially modern, adapted to the climate and the age, as the grand old styles of bygone days were in their own time."

We reproduce the "Guild Rules," which are appended to Mr. Fry's essay. They give a complete notion of his idea, and we should be glad to see them criticised by our readers. The subject would form no bad subject for discussion by the members of the Architectural Association.

GUILD RULES.

The Guild to be directed by one master.

The Guild to consist of one master, fellow-craftsmen of all trades employed in building, and apprentices; not exceeding the number of fifty in all.

Each craft to be under the guidance of a foreman.

The foremen to be appointed by the master.

Each craftsman to be engaged by the master to work a time, not exceeding three months, as a probationer, before being admitted into the Guild, during which time he shall receive wages according to the market rate.

The master to have complete control over the men and the works; his decision in all cases to be final; and his designs in no case to be deviated from without his consent.

The master to have the power to bind apprentices as members of the Guild.

The men to receive weekly wages at the market rate; the particular amount in any case of dispute to be settled by the master.

The capital of the Guild to be held in shares of £1 by working members of the Guild only.

Each member to be a shareholder.

The lowest and highest limit of number of shares to be held by any one member of the Guild to be

The interest of the shares not to exceed the rate of 6 per cent. per annum.

The profits of the Guild, beyond this, to be usually divided into four parts; one of which to be devoted to the shareholders as bonus, and the three remaining parts to all members of the Guild in proportion to their wages.

The dividend, bonus, and profits to be paid half-yearly.

The master to have full power to retain such portion of the profits as he may deem necessary for current expenses.

The master to receive per week a crown a head for each member of the Guild until it numbers over twenty members, exclusive of himself. Then, when it exceeds that number, he will only receive half-a-crown a week additional for each additional member.

The master should be able to draw and carve well; he should have studied the human figure, and have a general knowledge of anatomy. He should also be a thoroughly practical man, able, in case of emergency, to put his own hand to the work. His duty would chiefly consist in making all necessary working drawings, keeping the men employed, and generally managing the Guild; but he should also find time for stone carving. The workmen would have a claim upon him to instruct them in their work when they require it.

The master should be the largest shareholder, but otherwise in money matters be subject to the same rules as the other members of the Guild.

No shareholder under £100 to draw his shares with less than six months' notice, and those of £100 and upwards with less than a year's notice.

In the case of his suddenly retiring from the Guild, or dying, he or his heirs would be entitled to the interest on his shares, but to no part of the profits; also the same rule to apply in the case of any member being expelled.

The master to have full power to expel from the Guild any member who has been guilty of repeated misdemeanours or insubordination.

In the case of a criminal offence, a repetition would not be needed to empower the master to expel.

In the case of any difference of opinion arising respecting the highest limit of shares to be held by each member, it shall be decided that the right of each is in proportion to the weekly wages received.

The master to be quite irresponsible for any work in which he may engage the Guild.

The master shall settle any dispute between members that may arise.

The workmen to be represented by a committee of assessors.

Each craft to elect a representative to be a member of the committee of assessors, provided the craft numbers three or more members.

The assessors to be elected half yearly, and to be eligible for re-election.

The election to take place immediately before the payment of interest and bonus.

Every half year the assessors to appoint a chartered accountant (previous to the distribution of the bonus and the dividends) to audit the accounts.

This actuary's fee to be paid out of the funds of the Guild.

Any alteration of or addition to the rules of the Guild to be set led by the master, committee of assessors, and foremen—who shall together constitute the Board.

The Board shall arrange the holidays at Easter and Christmas.

The Board shall settle about the purchase of material and the price of work in contracting or otherwise. Any such decision to be subject to the master's veto.

The Board, for whom the master may act, shall legally represented the Guild.

The special object of this Guild is the erection of Churches, so it is thought proper that all its members should be in communion with the Anglican section of the Catholic Church.

SCIENCE IN ARCHITECTURE.†

(*Continued from p.* 32, Vol. XIX.)

SLATING.

THE Port Madoc slates are not all of inferior quality, as has often been inferred by the building community in Liverpool on account of their experience with the cheap slates from that port that have lately been introduced and used largely among us. When in Carnarvon, a short time ago, I saw some tons of good Port Madoc slates that would compare well with the best Bangor. The inferior slates may always be readily told by their dull, heavy colour and heavy sound; some of these inferior Port Madoc slates I have known to become literally washed away by heavy rains. The clear ring and bright appearance of good slates are always a protection to the architect against his being deceived; as a rule, the clearer the ring the better the slate. Slates are of best quality when taken from deep down in the quarry, the weight upon them causes closer texture. It is worth noticing that this rule does not hold in the quarrying of stone. Bath stone is, as a rule, found coarser very deep in the quarry than at a moderate depth.

In Liverpool, where roofs are generally flat, ton slates have the preference. The liability of chimney pots falling upon them, and the persistent walking upon roofs by tradesmen, however much they are cautioned to the contrary, make it advisable to use the strongest slates possible; Count slates

* "Guilds Desirable for Art and Artisans," by SAMUEL FRY. London: J. Masters.

† Read by WM. PARSLOW, Esq., before the Liverpool Architectural and Archæological Society.

look better and are more suitable for sharp roofs. In laying slates it is well to leave a small space between each, instead of fitting them quite close together; the space acts as a channel to convey the water to the slate below, but if fitted closely the water spreads and runs along the ridges of each slate, finding its way into the nail holes, and occasioning damp in the ceilings underneath; the numerous ridges in ton slates make this precaution especially necessary. There is great necessity for watching, not only the proper lapping of the slates, but also the cover of the nail holes by at least four inches; roofs are frequently defective for want of precaution in this particular. More lap is requisite with ordinary ton slates than with Count, since being rougher, they do not lie so closely; the neglect of attention to this is often a cause of damp.

CEMENTING.

Good cement face-work will stand well for many years without being painted. Cement that requires painting for durability and not for appearance only is of inferior quality; the principal object in painting cement work is to give it a fresh appearance. The front of the old Compton House, in Church-street, which had all the appearance of stone, was good cement that had not been painted. Good Portland cement may be always told by its bright colour of bluish tinge; the common is a dull slate colour. For face work two of gravel and one of cement is the best mixture, with the finishing coat half and half; too much cement in the mixture, making it technically too rich, is a common cause of cracks. Good cement the second day should be so hard that it cannot be broken without difficulty; that which will crumble easily in the fingers on the second day may be condemned at once as not good. Specifications often require that gravel only shall be mixed with the cement; that for mouldings should, however, be mixed with sharp sand, otherwise a smooth finish cannot be obtained. Portland cement should not be wetted on finishing; this perishes the cement; the first coat should be well wetted and soaked, then the last coat put on, and this not touched again with water; if rain gets to it before being quite dry it is very liable to perish; on the other hand, fine cracks, common in cement works, often arise through the under coat being too dry when the last is put on. If cement be put upon a wall liable to damp, the wall should be allowed to dry first, otherwise the cement may perish. If this precaution is not taken, and the damp in the wall does not dry out quickly or becomes renewed, the cement is sure to perish. The cracks that occur in the lining of rain-water tanks are not generally due to inferior cement, but to insufficient provision for bearing the weight of water. In making a rain water tank of brickwork it is well to build the half brick lining in cement, and then form the bottom of the sides of the tank with cant angle bricks; this takes a great deal of the pressure of the water off the bottom and throws it on to the sides, preventing leakages through cracks occasioned by settlement. The cant bricks may be put in after the tank is formed set in cement, but they are better built in as the work proceeds and bonded. For pointing about roofs hair mortar mixed with cement is better than cement only; it adheres when the heat and cold cause expansion and contraction, and does not crack through uneven drying; half and half is a right proportion. Good cement is often spoilt at buildings through undue exposure or otherwise by want of care; when the men are disposed to put this into their work, it becomes difficult for the architect to detect the evil until too late. It is necessary to be very strict with men on the first evidences of indifference.

PLASTERING.

In lathing for plasterwork laths should break bond—an arrangement technically termed snatching; this gives a good hold to the joists and makes a firm ceiling. Instead of the lathing being executed with rows of laths of equal lengths, joined by other rows of similar lengths, the bond should be broken by changing the length of the laths every five or six feet, and so causing one set to stretch across the joists to which the others have been fastened. This system takes more time than the ordinary system, and will not be adopted by men unless they are well looked after; it requires to be distinctly specified, on account of the extra labour. It is well to examine the cow hair provided for mortar before it is used; hair ought to be long and sound, but often it is brought to the building in bags, of short length and quite rotten, no strength in it. This sort of hair makes the plaster far worse than it would be without any; the plaster should also be examined before being put upon the ceilings by holding a little up with the spade; the quality in this respect can be detected by the hair hanging down. About six pounds of hair to one of mortar is a good proportion for top stuff; considerably less hair is needed in wall stuff. The finishing coat of plaster is sometimes set with hair in it; the plasterer picks out the white hair and beats it fine, then uses it with plaster of Paris. The last coat should be composed of about one-third plaster to two-thirds of lime-putty. The blotches or streaks sometimes seen in plaster walling are generally the result of bad work, though not so in all instances; a sooty or burnt brick in a wall will sometimes cause an unsightly patch on the plaster; marks from this cause have been known to come not only through the plaster, but the papering also. New ceilings ought not to be whitened: whiting eats into the new work and injures it. Lime for mortar should be burnt but little; much burning destroys its nature; the phrase "lime to be well burnt" is apt to mislead. When sluiced, lime is much better than when slaked in the common way; by sluicing I mean letting it fall to pieces, instead of running it with water; it becomes much more durable for mortar, and especially for pebble-dashing in mortar. If in mixing the lime for mortar or plaster the least bit remains whole, though as small as a pin head, it will burst in time and throw the plaster off the wall. This explains the cause of bursting occasionally seen on plastered walls. When the lime is run with water this defect is not so frequent as when the lime is allowed to fall; the latter mode, however, makes a superior mortar, but the lime for this purpose is best prepared two or three months beforehand, which precaution prevents any portion of the lime remaining whole; it involves extra trouble in turning it over, which makes the mortar very expensive. I have known the following practice to be observed in making good mortar:—The lime spread on the ground and a little water thrown over it, the whole then covered with sand and left for three or four days. The water slakes the lime into a powder; this is then mixed with the sand, and the whole passed through a sieve; it is then ready to mix with water to form mortar or plaster.

The best way of forming plaster cornices is to run a muffled mould, muffled with plaster of Paris, upon a ground of hair mortar, and leaving about ¼in. to be run afterwards with plaster of Paris and lime putty; this makes a much stronger cornice than is made by the present system, which is only a result of a wish to expedite the work and make it cheap at the expense of quality of workmanship. Plaster cornices often crack through there being common plaster mixed with the good; the common sets more quickly than the good, and the uneven setting produces cracks. It is a common practice to mix glue with plaster when there is doubt as to its quality; the glue causes the whole to take a longer time in setting.

PLUMBING.

No branch of the building trade requires more careful supervision in the execution of the work than this; defects creep in from all conceivable causes. I was recently asked to look at the iron cistern attached to a circulating boiler that had only been in use three years, but was now worn out; the house was of good class, £150 rental. I found, on examination, that the bottom was completely worn through, and accounted for it thus: no steam pipes had been fixed, and hence the pressure of the steam had exercised a force upon the bottom and sides of the cistern, resulting in the effects named, mild compared with what they might have been, for though the necessary steam pipes had been omitted, stop cocks to the pipes had been carefully fixed; evidently the steam had found its only escape through these pipes, and hence, had the stop cocks happened to have been turned at any time, there would then have been no possible escape for the steam, and an explosion must have resulted. The work had to all appearance been committed to the care of apprentices who did not understand it, and this is one source by which errors creep into this important branch of the building trade. On another occasion, on being asked to look at some property in course of erection, I found the lead pipes were all of considerably less weight than specified, and having them, as I thought, all changed, I discovered a length of the old piping left in a place where not exposed, the new being jointed to the old in such a position as almost to escape detection; there was an abundance of lead piping supplied for the purpose by the contractor, and the only conceivable cause for this deception was the disinclination of the man employed to put himself to the necessary trouble involved; and here again another source may be observed by which errors creep in. As another illustration, I recollect, on the completion of a first-class villa, part of the flashings proved to be of three pounds lead only; this, on being discovered, excited suspicion as to the whole of the lead work; on examination, however, the remainder proved correct, and the contractor, who was an honourable man, accounted for the circumstance by supposing the man whom he had employed when engaged with that portion of the work found himself short of material, and used what was nearest to hand. Such circumstances show special necessity for careful and intelligent supervision of this branch of works, since, apart from malevolence, carelessness and accident may result in so much defective work that, though not at once apparent, is in the end the more injurious. Where there is a disposition to deceive, the facilities in plumbers' work are so numerous that the results are often infamous. In a recent erection in this locality, the sole contractor for which was a most honourable man, the roof, on completion, proved to be flashed with zinc, painted to resemble lead, lead, as per specification, being so fixed so as to deceive in those positions likely be examined. The eye may soon become familiarised with the various thicknesses of of lead sheets and pipes, and it is advisable to make an effort to retain this familiarity. In some parts of the north of Scotland I found, on a recent visit, that ordinary flashing is executed with 7lb. lead; this is an unusual strength with us, but should be adopted everywhere when the flashings are long or exposed to unusual tempest. Ways and means are continually evidencing themselves for saving expense in the manufacture of the numerous fittings required in plumbers' work, and a strong check is required on the part of the architect; while, on the other hand, it is no less important that he make himself familiar with the numerous improvements that are continually being invented. To enlarge upon this latter subject would be out of place in this paper. Common brass work in taps, &c., is often deteriorated by a mixture of zinc in the metal; this may be known by the light yellow colour of the brass when polished; the best brass work, containing gun metal, has a much darker colour. Lead piping is often obtained cheap in Liverpool made of old pipes, from which the solder has not been extracted in the ordinary way, and which, being left in the lead, necessarily destroys its properties. The regulating cisterns of some houses I recently examined leaked in most instances, though they were comparatively new. I found the cause was in the valve being flush instead of being raised, a difference which considerably reduces the cost of cisterns, but detracts materially from their usefulness; the action of the plug and chain, assisted by corrosion, soon wears down the metal round the valve, causing it to leak; but when the valve is raised as it should be, the thickness of the valve has to be worn down, which is hardly possible, before this tendency to leak can begin. A little difference such as this makes all the difference between good and bad plumbing, and again in reference to fixing those fittings, the cheap ways of joining pipes may be soon detected but we cannot readily observe when taps and cocks are secured with a mixture of packing and solder instead of being neatly soldered only, which is essential for such fittings. Boss taps are best having a square knob attached to the boss to secure their hold in the wood or stone work, otherwise when the tap is screwed or unscrewed the pipe will be twisted and so injured. Since the subject of using lead pipes lined with block tin has been before us recently I will not, as I intended, go into its merits, particularly as the chemical properties of the Liverpool water have not the action upon lead that is experienced elsewhere, rendering such pipes necessary with us; but in reference to the subject I heard of a case of lead palsy, where the doctors were at first puzzled to find out how the lead had entered the patient's system; they subsequently found, however, that he had been accustomed to drink water taken from a lead pipe which for a considerable distance had been exposed to the outer air, and this circumstance was regarded by the medical men as the cause of the disease, inasmuch as

chemical action sets in through the influence of water on lead pipes, much more seriously when aided by the external air than when the pipes are covered in the usual way; the circumstances suggests the necessity of caution in covering lead pipes. Lead pipes are liable to be injured by vermin. I have known rats to gnaw holes in gas and water pipes, and make serious havoc in a single night. Covering pipes with gas tar is a good preservative, since rats will not touch this.

(To be continued.)

PARLIAMENTARY NOTES.

THE NEW POST OFFICE.—Mr. Eykyn, on Thursday week, asked the First Commissioner of Works whether the description of the new Post Office, published by a member of the Council of the Institute of Architects was correct, and if so, whether any steps would be taken to improve the elevation of that building. Mr. Ayrton said, to make his answer intelligible, it was necessary he should explain the matter. The gentleman referred to had described the design for the new Post Office as the ugliest ever conceived—that it was entirely devoid of all architectural knowledge and treatment, and want of skill applied to the work in consequence of the arrangement the First Commissioners of Works had made for carrying it out. The best answer he could give was to state what really had occurred. The design for the new Post Office was originally prepared by Mr. Fergusson, an officer of the Department of Works, under the direction of the noble lord the member for North Leicestershire, when that noble lord held office. Mr. Layard, when he took the office, did not approve of the design, and he, in conjunction with Mr. Fergusson, prepared what they considered to be an improved design. It was then sent to the Postmaster-General, and to the Treasury, and on their approving of it steps were taken to obtain tenders to carry out the works before he (Mr. Ayrton) became First Commissioner; and to show the value of the ridiculous criticism referred to, he would only add that the Council of the Institute of Architects had recommended Mr. Fergusson to receive her Majesty's Gold Medal for the great knowledge which every one knew that gentleman possessed in all matters connected with architecture.

Building Intelligence.

CHURCHES AND CHAPELS.

CHURCH ENLARGEMENT AND EXTENSION.—The Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels held its usual monthly meeting on Monday, at the society's house, 7, Whitehall, S.W. Grants of money were made in aid of the following objects, viz.:—Building a new church at Caldmore, in the parish of Walsall; rebuilding the churches at Church Lawford, near Rugby; Linkenholt, near Hungerford; and Martindale, near Penrith. Enlarging or otherwise increasing the accommodation in the churches at Bebington, near Birkenhead; Britford, near Salisbury; Bywell S. Andrews, near Newcastle; Crawley Down, near Worth, Sussex; Germansweek, near Launceston, Devon; S. Mary-le-Strand, London; and Thorp Arch, near Tadcaster, York. Under urgent circumstances the grant formerly made towards rebuilding the church at Burton-Pedwardine, near Sleaford, Lincoln, was increased. A grant was also made from the School-Church and Mission House Fund towards enlarging the school-church at Sewer's-end, in the parish of Saffron Walden, Essex. The society likewise accepted the trust of a sum of money as a repair-fund for the church at Cantley, in the parish of Sedberg, York.

BUILDINGS.

LIVERPOOL.—The London and North-Western Railway Company have erected at their terminus in Lime-street Liverpool, opposite S. George's Hall, a large hotel, which will be opened on the 1st of March. The building, which has eight stories, has been two years in erection, the architect being Mr. Waterhouse, of London, and the builders Messrs. Haigh & Co., of Liverpool. The hotel is built of white stone. Each corridor is 300ft. long. The hotel has stone flooring throughout, and is not only fire-proof, but each corridor is furnished with accessible hose and an ample supply of water.

TENBURY.—A hospital for the cure of infectious diseases has just been completed in connection with the Tenbury Union. The building consists of two stories, divided by a stringcourse of white bricks dentilled; a central gable with bargeboards and wrought-iron finial; a steep-pitched roof, tiled, with ornamental chimneys. The principal entrance in the front of the building has two arched doorways, leading respectively to the male and female wards. Exterior walls are 14in. thick, interior, ditto, 9in., the material used throughout being brick, relieved with bands of blue and white, with Bath stone dressings to doors and windows. On the ground floor are day-rooms for males and females, each room being 20ft. by 16ft., by 11ft. high. The male and female wards are on the first floor. Each ward contains four beds, is 11ft. 6in. high, and has the necessary accessories in the shape of closets, &c. The surgery is also situated on the first floor. The baths are movable on wheels. Mr. G. Page, of Tenbury, is the builder, and Mr. Ernest A. Day, of Worcester, is the architect. The cost has been about £1,200.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

RECEIVED.—J. M., A. R. & Co., Banks & Co., J. H. B., J. Hartley, C. Cosses, W. M. & Co., P. A., Hyde Clarke, C. J. J., J. K., J. R. White, J. G. B., R. G., R. & S., J. H. W., C. L. E., C. & Co., W. H. F., G.C., H. F., C. & Co., J. S. G., H. Son., P. & Co., P. & N. W., J. H., R. M. B.

SKETCH BOOK.—Thos. Garratt, Patrick Auld, J. Langham, Charles A. Jacques, Ed. H. Smales, H. H. Gribble, John Russell Walker, W. E. Brown, Thomas Lennox Walker. Thos. Batterbury, David Grant, and John Smith have recorded their votes. Contributors are respectfully requested to send in their votes at once.

H. W. R.—Apply to the Secretary of the Institute of British Architects, 9, Conduit-street, W.

EDWARD SKERITT.—Sketch returned.

A. E. PURDIE.—No charge is made for inserting illustrations of works. The one you sent will appear.

JAS. NEALE.—Sketch returned.

Correspondence.

CIRCULATING LIBRARIES.

(To the Editor of the BUILDING NEWS.*)*

SIR,—I am rather surprised to be reminded that the British Architects are the only scientific body in London that do not circulate their books among their members. In all other societies this is one of the chief privileges we get for our subscription. It is not supposed that a man engaged in professional pursuits can spend hours in a library between 10 or 12 a.m. and 4 p.m, and therefore it is provided that he can have books necessary for his pursuits. It is always understood that any one who is really engaged in the prosecution of any study shall have the use of books for even a lengthened period, provided he does not interfere with the convenience of any other member.

Certain books of reference must be always retained in the library; but, in a well-constituted society, there are duplicate sets even of some of these for the convenience of home students.—I am, &c., HYDE CLARKE.

LIMES AND CEMENTS.

SIR,—In your excellent report of my paper, read before the Civil and Mechanical Engineers' Society, it is stated, with regard to blue lias lime, that—"The mortar is not of itself sufficiently hydraulic to set under water; but, if allowed to remain for twenty-four hours, the water has no effect upon it."

This is not correct; and is only true so far as the richer qualities of the blue lias lime are concerned. The lime made from the poor lias is eminently hydraulic; and concrete made with this lime, in the proportions of 6 parts of shingle to 1 part of lime (taken full), may be tipped into a river from a stage, and at the end of a fortnight will have become so hard as to be impenetrable to a pick. I should feel obliged by your inserting this in your next.—I am, &c.,

H. E. HUNT.

[*** In Mr. Bancroft's paper on this subject, on page 125, first column, line 24 from top, read from *one to three* parts of lime of the ordinary sort, instead of "seven to three," &c.—ED.]

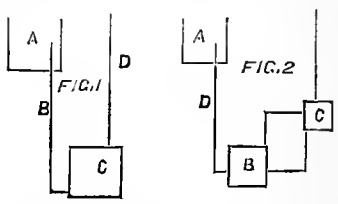
KITCHEN BOILER EXPLOSIONS.

SIR,—I have read the remarks of "T. S." at page 136. As to his first paragraph, he may as well tell us that the tea-kettle cannot explode as to refer to the kitchen "boiler," or rather *pan*, with movable lid. What has that to do with the close boilers, such as your correspondents were referring to?

As to his second paragraph, it is a perfect muddle, and judging by it, the writer either does not understand properly what he is writing about, or else is unable to express himself properly. So I must just refer your readers to my remarks in your issue of 10th inst., a little study of which, in connection with the sketch, will be useful, especially to non practical men.

"T. S's" *cistern*, closed hermetically, is not, properly speaking, what is generally understood by the term "cistern," but then becomes a *tank*, as plumbers term it, which tank acts as an enlargement of the boiler; *e.g.*, a house of four flats may have the cold cistern in garret at top, and boiler in kitchen in lower flat, and, having no hot cistern, as I gave sketch of, they may place a close tank in corner (say) of kitchen near boiler, so that the water revolves between this tank and boiler as shown in fig. 1, A being the cold cistern, B the boiler, and C the tank. But it will be observed in this case that the revolving only takes place between B and C, the supply-pipe to boiler D keeping always cold, and merely acts as supplying cold water to B as the warm water is being drawn off from C. Then the idea of placing a "safety-pipe" up a chimney fifty feet high is simply absurd. It is not hot-water apparatus for heating a church, hot-house, or school-room we are treating of. "T.S." is right, however, as to saying that the up-pipe should not be put too far into the top of the boiler, as also regarding inclining the boiler the wrong way.

Fig. 2 is a sketch of a close kitchen boiler fitted up, as many are, without a hot cistern, and which style is liable to be the cause of explosions during frost. So far as *safety* is concerned, this, and the *tank* system above sketched, are about equal.



A is the cold water cistern from which boiler is supplied. B the cold water pipe going down to boiler. C is the boiler. D the hot water or expansion pipe—from which the branches may be taken off—which rises higher than cistern and goes to outside, say to roof. In this case there is *no circulation*, and unless the cold pipe was protected by felt a cold draught in frosty weather might soon freeze it, and if fire went out, the pipe D also, before morning; in which case, if large fire was put on, away goes the explosion.

The third paragraph of "T. S." seems to me rather curious. The fourth is sensible when applied to patent extras. The fifth shows something wrong, for had the pipes been properly covered with felt we hardly should expect them to have been frozen; while the fact of the man taking away the "safety-pipe" shows how little value can be sometimes put upon such *extras*. Besides, supposing the people in house, depending upon such a safety, used boiler, and it got empty, then a sudden thaw coming on, what about boiler if red-hot? while, during the frost, there was the inconvenience of want of water? Therefore, for safety, convenience, and non-liability to go wrong, the plan in your issue of the 10th inst. will be found the best and safest, as well as simplest, if the things are done as I said.—I am, &c., PLUMBER.

Feb. 17th, 1871.

SATURDAY HALF-HOLIDAY.

SIR,—Allow me to thank you for inserting my letter on the above question in your impression of the 11th inst. Of 94 communications sent me on the subject I find the result to be that 83 of

the offices close on Saturday earlier than on the other five working days of the week, the remaining 11 slaving on as usnal. I presume I may be allowed to take this result as a fair representation of the extent to which the half-holiday is recognised by the architectural profession. If so, the proportion will be seen to be nearly 8 to 1. The question then comes to be, what is to be done with this ninth man who refuses to do as the majority of his brother architects do? Suggestions rise in one's mind with regard to him which have more direct reference to tailors than architects. At the same time, it would be a great matter to impress him with the fact that he is doing himself and his assistants a great injustice; for the advantages of the half-holiday are as much on the side of the principal as the assistant.

To speak of these advantages generally, they are summed up in recreation and study. Now I maintain that the man who has a few hours of every week to give to either of those purposes, benefits not only himself but his employer. If he gives the time to recreation, he is certainly physically able to do more work than if he had no time during the week to devote to such a purpose. If, on the other hand, he gives his time to study, his employer of course receives the benefit of it in having his work more carefully and skilfully done. I contend, therefore, that architects who deny their assistants this boon stand much in their own light, and deprive their assistants of the opportunity of keeping apace with the other young men in the profession.

May I be allowed to suggest that the Institute would be doing good service to the profession were it to strongly recommend to all architects the giving of the Saturday half-holiday.

I beg to thank those gentlemen who have so kindly assisted me in making public the above figures. A. Y. Z.

SOCIETY OF ARTS.—ART WORKMANSHIP 1870-71.

SIR,—Under this head in your issue of the 3rd, inst., occurs the following:—"No 13, a panel in marqueterie, executed by W. Clayton, from designs by Mr. Bassett Keeling, is crude and inharmonious in colour."

Permit me to explain that I have no knowledge of W. Clayton, nor of the work in question. Unless the mention of my name is a mistake, I can only assume a surreptitious use to have been made of one of three drawings prepared by me, and from which Nr. Steinitz, of Camberwell Hall, executed the panels for the pulpit of my church of S. Andrew, Camberwell, some years since.

The panels in question represent half-length figures of "Moses, Elias, and Christ" as "the Law, the Prophets, and the Gospel," and are the only marqueterie panels for which I ever supplied the designs.

If my design has been used, I am obviously not responsible for the harmony of colour in a work not executed under my control or superintendence; and if there is a mistake, it is the more desirable, in justice to myself and the actual designer, that the mistake should be thus corrected.—I am, &c.,

BASSETT KEELING.

THE ART WORLD.—SOUTH KENSINGTON.

SIR,—I beg to be allowed to make a few observations upon the editorial article under the above head, that appeared in the *Echo* newspaper of the 16th inst., in which the writer commences with the astounding assertion of the entire novelty of the design for the Hall of Arts and Sciences, now approaching completion, when that design is notoriously a direct copy of the Amphitheatre of Vespasian, at Rome, commonly called the Coliseum. The writer further alludes to the special beauty of the perfect fitness of the architecture for the intended uses of the building, an assertion literally true as regards the Coliseum of Rome, but inapplicable to the South Kensington Hall, for I have yet to learn that the arena is to be made use of for gladiatorial shows or other exhibitions. In fact, the uses of the Coliseum are actually to be reversed in the hall, by placing the audience in the arena, and exhibitors and exhibitions in the seats and galleries above—a disposition that will render this magnificent building nearly useless.

In regard to the question of beauty of design, I will venture to assert that, given the plan and dimensions, an equally good design could have been produced in any architect's office in London.

It is also rather trifling with the subject to urge the experimental mode of carrying on the building, when the builders had such a noble example before their eyes.

Moreover, the hall is intended to include a picture gallery at the top, which will require, of course, numerous flights of stairs, or the disagreeable, and sometimes dangerous alternative of mechanical lifts. How much more convenient, and far more economical to have built an independent gallery on flat ground! Again, the desire now expressed that the delicate internal machinery of the great organ should be exposed to dust and smoke, is another absurdity that will require an army of cleaners all the year round. The true position of that unsightly musical machine, however profusely ornamented and gilded, would be in a chamber out of sight of the audience, but having a free acoustic communication with the hall.

To all these maladaptations of an ancient building to modern purposes is superadded the error of placing the speakers or singers at the greatest distance from their hearers; whereas, if the broadside principle had been adopted, with the stage or platform at the extremity of the lesser axis, the voice would have had only half the distance to traverse, and all other difficulties would have disappeared. The broadside arrangement would also afford the convenience of a wider stage than that of the largest theatre in London—an appliance that is now found to be indispensible in order to render any building intended for public exhibitions remunerative. The days of Exeter Hall are numbered, notwithstanding its very central situation, with nearly equal portions of London, east and west of it; while the Kensington Hall is situated in a remote suburb with the whole of the metropolis on one side only. In one respect, the ancients had a great advantage over us moderns, there was no charge for admission; ingress and egress was therefore free from all difficulty. The Coliseum at Rome had eighty entrances of about the dimensions of a barn door, while the Kensington Hall has only four.

Under these circumstances it is idle to talk of high art in designs for metropolitan public buildings, because the avenues of approach, which ought to be grand and noble to correspond with the structure, are obstructed and end up with check-takers' boxes and their bars, besides that hideous engine of inquisitoral torture, the counting turn-stiles.

The so-called Central Albert Hall of Arts and Sciences, like everything else, is a commercial money-getting undertaking, and therefore the largest possible space is secured for the visitors, while the performers are screwed into the smallest. At the conversazione held at South Kensington by the Society of Arts, none of this scandal takes place, for each visitor is personally presented to, and received by some of the high authorities of that society.—I am, &c., C. E.

NEW LAW COURTS.

SIR,—The difference between the highest and lowest tenders (£31,000) for the foundation works, in your correspondent "F.'s" opinion is a matter not worthy of much, if any, consideration. His attempt, however, at a simple solution of the mystery respecting it, tends to make a bad matter worse, and is not only unsatisfactory, but very indiscreet. He accounts for the highest tender thus:—"Perhaps the contractor put them so for the purpose of keeping their names before the public, and possibly for fear of giving offence to the architect for not tendering, and without having the remotest intention of securing the job." If contractors do tender in this reckless, unmeaning way, having no other aim than "wireing in to keep their names up," of course one's wonder ceases at the wide range of tenders; but such a course of procedure must operate detrimentally to, and is unworthy of men in position; is a gross insult to an architect; makes tendering a burlesque; and a bill of quantities useless.

I am fully aware, though only a noviciate (I have no desire to be an "initiate" in anything dark, unfathomable, or questionable), that errors, both of omission and commission, are often perceptible in "bills" of surveyors, as well as in contractors' judgments, for none of us are infallible; but if the bills were to emanate from one source, the same to be approved and verified by the architect, discrepancies of much moment would be less likely to arise than if several surveyors contemporaneously supplied, as all competitors would compile their estimates from the same basis.—I am, &c., J. M. L.

Intercommunication.

QUESTIONS.

[2131] PLASTER CASTINGS.—Will any of your readers recommend me a cheap treatise on plaster castings?—C. T. T.

[2132] CUBING BUILDINGS.—In cubing a building for an approximate estimate of cost, is it in two-story dwellings customary to include in the measurement the depth of chamber floor-joists, the thickness of internal walls, and the space occupied by chimneys? Would the cellars also be measured? As a rule, is it usual to measure internally or externally, say from floor line to ceiling, or from ground line to and including roofs?—WILTSHIRE.

[2133] COMPETITIONS.—Would some of the subscribers to "Intercommunication" kindly favour me with their opinions on the following?—The authorities of a country town invite architects to send in competitive designs for a new townhall. An architect' assistant, possessed of more than an average amount of ability, prepares a design during his leisure hours, which is eventually chosen by a committee appointed to adjudicate. What I desire to know is, would the authorities be justified in rejecting the design after finding that its author was an architect's assistant only, or could they be compelled to abide by their decision?—T. C.

REPLIES.

[2125] PROBLEM IN CONSTRUCTION.—The best plan will be to have a damp course of asphalte above the ground outside and under the hall floor inside, half way through the wall thus, D D D ground, and B floor of hall.

The walls of this hall being built with a hollow space admit of this being done with success.—W. R. A., Uckfield.

[2125] PROBLEM IN CONSTRUCTION.—If "A Cautious One" wishes to deserve his title, he will put the proof course under the joists of hall, and form a dry area outside.—P. E. M.

[2125] PROBLEM IN CONSTRUCTION.—A damp-proof course is necessary, and should be placed immediately below the floor-joist or wall-plate. Taylor's patent damp-proof course, or Doulton's, would be the very best material for the purpose, as it would answer three purposes, viz., completely prevent damp from rising, bond the two portions of wall solidly together, and admit the air beneath the floor of hall. Taylor's can be procured from Mr. George Jennings, and Doulton's from Henry Doulton & Co., High-street, Lambeth. They (the damp-proof courses) are very similar in character.—WILTSHIRE.

[2125] PROBLEM IN CONSTRUCTION.—Put in damp-proof course at two levels, one in the external half of wall above ground line, and the other in the internal half below the floor; neither course to project over the space between.—A. Z.

[2125] PROBLEM IN CONSTRUCTION.—If the floor of the hall is to be wood place damp course below it.—P.

[2126] PLUMBERS' WORK.—I have used lead-headed nails, but as for "lead-soldered tacks," I would wish to know where they are said to be used, &c.—P.

[2126] PLUMBERS' WORK.—Lead soldered tacks mean nails or tacks for securing the sheet lead to woodwork, the heads of which are driven beneath the plane surface of the lead by means of countersunk holes made in the wood; these being then filled up with solder prevent, of course, water penetrating in the holes made by the nails.—WILTSHIRE.

[2127] ANCIENT CHURCH ARCHITECTURE.—A variety of books on this and other architectural subjects can be obtained at reduced prices at Mr. Batsford's, 52, High Holborn, and who would, no doubt, gladly send "W. H. B." a catalogue.—WILTSHIRE.

[2128] ISOMETRICAL PROJECTION.—The "Illustrated London Drawing Book," by Scott Burn, price 2s.—WILTSHIRE.

[2129] MANSARD ROOFS.—The roof delineated is not a mansard. The mansard roof is shaped thus:

Call the roof what it is, a high or tall roof.—P. E. M.

WATER SUPPLY AND SANITARY MATTERS.

PROPOSED PURE WATER SUPPLY FOR SOUTH LONDON.—Waterworks are in course of construction at Highland Park, Leatherhead, on the edge of the chalk range. The supply of water obtainable is practically unlimited. The water is said to flow under-ground through fissures in the chalk like a huge lake, and the wells are replenished as fast as exhausted by any pumping apparatus at present applied. At present the springs overflow into the Mole, the waters of which run into the Thames at Moulsey and Thames Ditton. A portion of these waters, after being contaminated with the drainage of the Upper Thames, is taken from the river at Hampton and other points for the supply of a great portion of London. Why not, suggests a local paper, intercept the waters while pure in their chalk beds, instead of allowing them to run into the Thames, and then having to filter and re-purify them—the latter very ineffectually? The supply under the chalk region will, it is estimated, certainly be found ample for the southern and eastern waterworks, which seem at present to be the worst supplied in point of quality of any of the London companies. As to cost, nothing is required but a pumping station and reservoir on the top of one of the chalk hills; the softening would be done at the reservoir, and pipes might be laid along the side of the South Western Railway to Lambeth, a distance of fifteen miles—only at much less cost and inconvenience than is caused by taking up roads and streets.

THE LAMBETH POTTERIES' NUISANCE.—The action taken by the Lambeth authorities and the Archbishop of Canterbury in order to stay the long-standing nuisance arising from the noxious vapours allowed to escape from Messrs. Doulton's and Messrs. Stiff's potteries having proved ineffectual, the inhabitants of the Middlesex side of the river are bestirring themselves in the matter, and the Westminster District Board of Works have resolved to instruct its solicitor to take the necessary steps for the abatement of the nuisance. When the matter was brought forward by the Archbishop of Canterbury a short time back, the magistrate ruled that under the existing Acts bearing on

the subject he had no power whatever to convict, as the nuisance complained of arose from the escape of white vapour, whereas the Acts only made penal the escape of dense black smoke. If this is the case, it is to be hoped that, in the new Sanitary Act which will follow upon the Report of the Royal Sanitary Commission, this imperfection and inequality in the law will be remedied.

STATUES, MEMORIALS, ETC.

CHARLES DICKENS.—A bust of the late Charles Dickens has just been executed by Mr. W. F. Woodington, jun. The sculptor is the son of the artist who designed the bas-relief of "The Nile" on the Nelson column, in Trafalgar-square, and that to the memory of Wellington in S. Paul's Cathedral.

LAND AND BUILDING SOCIETIES.

MARKET HARBOROUGH.—The first annual meeting of the Market Harborough and District Permanent Building Society was held a few days ago. During the short time the society has been in operation upwards of 370 members have been enrolled as depositors; £400 has been advanced on mortgage, and other applications for advances have been received, which are under consideration; and, in order to estimate the general working of the society, it is fully hoped and anticipated that as future funds become available for investment there will be no lack of borrowing members.

PEOPLE'S CO-OPERATIVE BENEFIT BUILDING SOCIETY.—The twenty-third annual meeting of this society was held at Deptford on Wednesday week. The report of the directors reported a steady increase in the capital of the society, which has now reached £46,392. The amount received during the past year under the head of "member's subscriptions" was £13,725 17s. 0d., and the withdrawals were less by £1,150 than in the previous year. £5,215 was advanced during the year. After providing for every liability there is a realised profit of £472 12s. 6d. From this the directors recommended the payment of a bonus of 2 per cent. on all shares two years old and upwards; also £80 to the directors and £20 to the secretary.

WARWICK AND WARWICKSHIRE BENEFIT BUILDING SOCIETY.—The annual general meeting of the above society was held in the Court-house, Warwick, on Monday week. The report showed that the total receipts for the past year amounted to £3,025 14s. 6d., and that after paying expenses a balance of £542 4s. 11d. remained in the banker's hands, and a reserve fund of £38 0s. 11d. 37 shares have been sold at the average premium of £2 10s., which enables the committee to pay a profit of 3s. per share in addition to the annual interest of £4 per cent.

LEGAL INTELLIGENCE.

MOST IMPORTANT TO THE BUILDING TRADE. — DECISION ON THE LONG-PENDING QUESTION OF "GRINDING MONEY."—This was an action brought at the Westminster County Court, February 21st (before F. Bayley, Esq., Judge), by the plaintiff, William Hayden, a journeyman carpenter, against the defendant, Mr. Charles Fish, carrying on an extensive trade as a builder at Cambridge Wharf, Pimlico, to recover 2s. for "grinding money," and 1s. loss of time in going for it. The case excited great interest in the building trade, by members of which the Court was throughout its hearing crowded.—Mr. Smith, solicitor, Denbigh-street, was for the defendant.—Plaintiff stated that he had been in defendant's employ seven months up to the 28th of January last, at mid-day, and was then suddenly discharged without previous notice, when claiming 2s., as usual, for, "grinding money," viz. sharpening tools, it being refused, these proceedings were taken.—By Mr. Smith: He was at the time at work at the houses 18 and 19, New Bond-street, and paid weekly at temporary offices in Avery-row, where after he was dismissed by Petters, the foreman, applying to the clerk who paid him for the first sum now charged, the reply was that he knew nothing about it, and that he had better see defendant, for which he went purposely to the wharf. He had been in the trade many years, and had, when claiming, always received "grinding money."—Several journeymen carpenters gave corroborative evidence as to the charge so made being right; one of them saying that he had been paid the same by Mr. Myers, the well-known builder.—Mr. Smith, in reply, said that although the claim was for so small an amount, the case was one of great importance to all and every one connected with the building trade, the question of the allowance of "grinding money" by masters having been in abeyance ever since the celebrated "lock out" or strike in 1859, since which the hour system, or paying by the hour, had been adopted, and the "grinding money," which was only then in some instances allowed, discontinued. In proof of such being the law acted upon, he would refer to the report of a similar case as the present heard before Mr. Whitmore, Judge of Lambeth County Court, who decided in favour of defendant. He wished, also, to say that the paying of such was discountenanced by some of the greatest firms in London, including Brown & Henderson, Kelk, Myers, Cubitt & Co., and others. He would now call his client.—Mr. Charles Fish, the defendant, deposed that he had been in business 22 years, and, as Mr. Smith said, knew of no "grinding money" being allowed since 1859, and then only done by custom in the trade.—Mr. F. J. Mullett said that out of 15 years he had been clerk, he had acted as such for 12 to defendant, and never knew the allowance of such money by him or any other builder.—His Honour, in giving judgment, said he was very glad the case heard by Mr. Whitmore had been introduced, for in consequence of that, and there being a variety of opinions on the question, he had convened a meeting with that gentleman, Messrs. Kelk, Myers, Cubitt, and others, the result of which was his opinion that the so-called "grinding money" could not be claimed as a right, there being no law to make it payable. Under these circumstances, merely adding that the charge of a shilling for going to Cambridge-wharf was absurd, his decision would be for the defendant. Judgment so entered, with costs.

Our Office Table.

INSTITUTION OF SURVEYORS.—At the ordinary general meeting, held on Monday, the 13th inst., the following name was read and passed for ballot, viz.:—as Associate,—Thomas John Robert Davison, Bedford Office, Montague-street, W.C. The adjourned discussion on Mr. Mathews' paper, entitled "The Valuation of Annuities and Reversions Dependent upon Terms of Certain Duration," was resumed, and after a long debate was again adjourned to the next meeting. The following candid ates were balloted for and declared duly elected:—As Members—Richard Albert Notley, 27, Royal Exchange; Perry St. Quintin, 27, Royal Exchange; as Associates—Edward James Castle, 4, Brick-court, Temple; Arundel Rogers, 2 Paper-buildings, Temple; Hugh Shield, 3, King's-bench-walk, Temple; Julian Horn Tolmè, 1, Victoria-street, Westminister; Frederick Meadows White, 4, Paper-buildings, Temple. The next meeting will be held on Monday evening, next, the 27th, when the discussion on Mr. Mathews' paper will be resumed. The followi ng candidates will be balloted for, viz.:—As Members—Rowland George Fisher, 17, Great George-street, Westminster; William Frederick Hart, 16a, King's-road, Bedford row; William Knowles, King-street, Gloucester; as Associate—Joseph Quick, jun., Sumner-street, Southwark.

BATHING.—Bathers will be glad to learn that there is a prospect of getting a decent bath at Henley-on-Thames. The great complaint of boating men and visitors last season was that there was "nowhere to bathe." We understand that a company is in course of formation to provide good accommodation, and a plan prepared by their architect, Mr. F. Haslam, has been laid before the Thames Conservancy Board and obtained their sanction.

THE VICTORIA EMBANKMENT.—During the late frost very little progress was made with the approaches to the Thames Embankment. A portion of the approach, however, from Arundel-street, leading east, is now open to traffic, and the outworks in the direction of Craven-street are still at a standstill. It may be mentioned that it is the intention of the Metropolitan Board of Works to erect an ornamental fountain on the embankment, near the Charing Cross Railway Bridge, at a cost not exceeding a £1,000. The designs for the same have been submitted, but not yet finally decided on. The Board has approved of a design for a memorial fountain, in honour of the late Judge Payne, the cost of which will be defrayed by the Metropolitan Free Drinking-Fountains Association.

INDIA.—The Calcutta Municipality have determined to have a market of their own, and have applied to Government to authorise a loan.—The new Palace, built by the Public Works Department of India on Government account, for H.H. The Nawab at Moorshedabad, having already cracked in many parts, the engineers and architects have been called on by the Government for an explanation. What will the new Engineering College do?

THE FORTHCOMING EXHIBITION.—The encaustic and majolica tiles to be exhibited by the firm of Messrs. R. Minton, Taylor & Co., of Stoke-upon-Trent, have been made chiefly from designs by Mr. E. Welby Pugin and by Mr. John Gibbs, of Oxford. We understand that during the last three years Mr. Gibbs has been similarly engaged for other eminent firms, and is now completing a set of designs for Messrs. Malkin, Edge & Co. This will make the number of his designs for tiles made in the time stated over a thousand.

THE TAY BRIDGE.—We understand that a fresh contract has been entered into for the construction of this bridge. The present contractors are Messrs. Berberg & Co., of London. The contract price for the work is £217,000, or about £12,000 less than the first contract. The bridge is to be supported on a number of columns. Cylinders are to be sunk in the river and deposited on the rock foundation. Machinery is fitted up in the cylinder, and by means of it the ground at the base is brought into a state resembling that of mortar. The great weight of metal gradually forces itself through the soft substance, and ultimately secures a firm foundation on the rock. Workmen are then able to build the column, which is encased in the iron cylinder. The bridge will consist almost entirely of iron.

NORTHERN ARCHITECTURAL ASSOCIATION.—The annual meeting of the Northern Architectural Association was held on Tuesday week at Newcastle-on-Tyne. The report (which congratulated the society on its increased prosperity) having been adopted, Mr. A. M. Dunn read a paper on the "Reparation of the Roof of S. Mary's Cathedral, Newcastle, which was affected by dry rot," after which the President, Mr. F. R. Wilson, read his annual address.

NEW PREMISES FOR THE LONDON SCHOOL-BOARD.—Our readers will be interested in learning that the London School-Board have taken the house, No. 33, New Bridge-street, Blackfriars, for three years. This is the building which has been so favourably noticed by architectural writers as providing an example in the right direction for the development of a style of street architecture suited to modern requirements. It was built from the designs of the late Mr. Woodward for the Crown Insurance Company, but having been purchased by the Chatham and Dover Railway Company at the time of the construction of the Ludgate-hill Station, it has remained unoccupied for the last three or four years.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—*Institution of Surveyors.*—Adjourned Discussion on Mr. Mathews's paper "On the Valuation of Annuities and Reversions Depeodent upon Terms of Certain Duration." 8 p.m.
Architectural Association.—"On Limes and Cements." Lecture IV. By Lieutenant-Colonel Scott, R.E. 7.30 p.m.

TUESDAY.—*Institution of Civil Engineers.*—"An Account of the Basin for the Balance Dock, and the Marine Railways in connection therewith, at the Austrian naval station at Pola, on the Adriatic." By Mr. Hamilton E. Towle,. 8 p.m.

WEDNESDAY.—*Society of Arts.*—8 p.m.

FRIDAY.—*Civil and Mechanical Engineers' Society.*—"On Tin-mining in Cornwall." 7.30 p.m.

SATURDAY.—*Associated Arts' Institute.*—"On Fresco-painting." By W. Cave Thomas, Esq. 8 p.m.

Chips.

The honour of knighthood is to be conferred on Mr. Boxall, R.A., on his retirement from his post at the Royal Academy.

The Westminster District Board of Works has resolved to purchase of the Metropolitan District Railway Company a small piece of land near the Broadway railway station, for the purpose of effecting a street improvement, provided the same can be had for £150, of which sum the Metropolitan Board has agreed to contribute one-half.

The library and galleries in the Vatican have been declared to be national property by the Italian Parliament, notwithstanding ministerial efforts to the contrary.

It is proposed to erect a temporary small-pox hospital on the ground between the Thames Embankment and Cannon-row, immediately adjoining the end of Richmond-terrace, Whitehall.

A large painting of the Transfiguration has been presented to S. Mary's Church, Prestbury, by Cheltenham friends.

On the 14th inst., Mr. W. H. White, Assistant-Surveyor, Norwich, was elected Surveyor to the Oxford Local Board of Health. There were 69 candidates for the appointment.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

BOLTON.—Contract C.—March 3.—The Corporation of Bolton are prepared to receive tenders for the joiners' work, plastering, painting, glazing, and plumbers' fittings required for the completion of the new town-hall. The drawings and specifications may be seen, and bills of quantities obtained, on application at the offices of Mr. William Hill, architect, Park-square, Leeds; or at the offices of Mr. George Woodhouse, architect, St. George's-road, Bolton, between the hours of 10 a.m. and 5 p.m., from the 16th day of January next to the 3rd day of February next. Sealed tenders are to be sent in not later than 12 o'clock at noon of Friday, the 3rd day of March next, addressed to the undersigned at the Corporation Offices, Acres Field, Bolton, and endorsed "Tenders for the Town-hall, Contract C." R. C. Hinnell, Town Clerk.

SUDBURY WATERWORKS, March 4.—Contract No. 4. Construction of a covered service reservoir. Contract No. 5. Supply, laying, and fixing of about five miles of cast-iron water-pipes, with sluice-cocks, hydrants, and other appliances, and some ironwork required for reservoir. Mr. Hennell, 7, Salisbury-street, Adelphi.

EAST BARNET (Herts), March 1.—For the construction of about 4,800 yards of outfall sewer, of brick or stoneware pipes. Messrs. Lawson & Mansergh, 3, Westminster-chambers, Victoria-street, Westminster.

HARWICH, March 7.—War Department triennial contract for builders's work. Royal Engineer's Office, Colchester.

ROPLEY (Hants), March 4.—For the erection of a house and offices at Lyewood, Ropley, Hants, for Mr. John Lilly-white. W. H. Hunt, architect, Alresford.

NORWICH, March 7.—War department triennial contract for builders' work. Royal Engineer's Office, Colchester.

ST. JOHN'S, HAMPSTEAD, March 3.—Contract for road materials, and for paving and kerbing. William Gribble, Vestry Clerk, Vestry Offices, New End, Hampstead.

HUNSTANTON, March 4.—For the erection of nave and north aisle of new church at St. Edmund's. Frederick Preedy, architect, 13, York-place, Portman-square, London, W.

MAIDSTONE, March 6.—War Department contract for bricklayers', masons', paviors', carpenters', plasterers', slaters', plumbers', smiths', painters', glaziers' and paperhangers', and gasfitters' work. Royal Engineer Office, Chatham.

HINCKLEY LOCAL BOARD, March 6.—For the sinking of a bore-hole and well, on the site of their intended waterworks. Samuel Preston, Clerk to the Board, Hinckley, Leicestershire.

HEADBOURNE WORTHY, HANTS, March 4.—For the erection of a gentleman's residence and stable buildings, at Headbourne Worthy, near Winchester, Hants. John Dolson, St. Swithin's-street, Winchester.

FAWSLEY (Northamptonshire), March 13.—For the erection of farm buildings. Mr. Waters, Fawsley Estate Office.

MAIDSTONE, March 2.—For the erection of the proposed new schools for girls and infants, on St. Faith's-green. E. W. Stephens, architect, 87, Week-street, Maidstone.

HEREFORDSHIRE, March 7.—Thornbury United School.—For the erection of a school for fifty-four children, with mistress's residence, at Thornbury, three miles and a half from Bromyard. W. West, solicitor, Bromyard.

COLCHESTER, March 7.—War Department triennial contract for builders' work. Royal Engineer's Office, Colchester.

PORTSMOUTH, March 10.—War Department triennial contract for builders' work. Royal Engineer's Office, Portsmouth.

BANKRUPTS.

(TO SURRENDER IN LONDON).

Charles Taylor, John-street, Upper Holloway, contractor, Feb. 28, at 12.—Thomas Hutchings, Alwin-road, Lewisham-road, contractor, March 8, at 12.

(TO SURRENDER IN THE COUNTRY).

George Hardy, Kirkdale, near Liverpool, builder, Feb. 28, at Liverpool—Henry Stevens, Swaffam Bulbeck, builder, March 3, at Cambridge.—Jane Stow Nelson, plumber, March 9, at Burnley.

PUBLIC EXAMINATIONS.

March 17, W. I. Jones, Grove-road, Acton, builder—March 23, J. West, Chichester, builder.

DIVIDEND MEETINGS.

March 11, J. Chesterfield, Godmanchester, cement factor—March 7, R. Askew, Great Ponton, builder—March 7, J. Wright, Stamford, ironmonger—March 15, E. Finch, Chepstow, engineer.

DECLARATIONS OF DIVIDENDS.

J. Perkins, East Dereham, builder, div. 4s., Feb. 27—T. W. & H. Panton, Monkwearmouth, ironfounders, div. 2s. 10d.

SCOTCH SEQUESTRATIONS.

Adam Lumsden, North Middleton, near Gorebridge, builder, Feb. 27, at 2—John Henderson, jun., Helensburgh, ironmonger, March 2, at 12.

PARTNERSHIPS DISSOLVED.

Norcliffe & Co., Sowerby Bridge and elsewhere, masons—Bay & Brett, Ventnor, builders—W. & S. Collier, Bridgend, Glamorganshire, lime merchants—J. & T. Parralet, Holywell row, Shoreditch, sanitary pottery dealers.—Rigby & Sager, Blackpool, joiners—Lewin & Clarke, Barrow-on-Soar, lime merchants.

THE BUILDING NEWS.

LONDON, FRIDAY, MARCH 3, 1871.

ARCHITECTURAL PROBLEMS OF THE DAY.

WE noticed a week or two since two very different sorts of originality which show themselves in various classes of modern work : one sort sterile, purposeless, and ending in itself ; and another fruitful, suggestive and bearing the germs of future development : and we tried to point out that the valuable kind of originality is not that of the artist who sits down deliberately to produce novelties, but of the one who, having new problems to deal with, inevitably finds, when he has mastered them, that he has arrived at new solutions. There is no lack of such problems at the present moment—seldom perhaps, since architecture first began, have there been so many : and in calling attention to a few of them we may possibly help to turn into a useful channel some of the force which is now wasted in vain and aimless efforts. To arrange in a connected scheme all the questions which occur would occupy, not an article, but a book ; we can here only attempt to name a few of them disconnectedly, as they happen to suggest themselves.

The first, and most urgent class of problems, includes those which relate to general design and arrangement. The modern architect has to deal with a multitude of buildings for which no ancient precedents exist : how is he to treat them ? Suppose, for example, he is planning a large church, say for 1500 people, and suppose his clients are so unreasonable as to wish all these people to be placed in sight and hearing of the service, how is he to effect this at moderate cost with architecture worthy of the name ? Here alone is a problem, to begin with, which one man's lifetime would be too short to solve completely. Here is not only an opening, but an urgent need for originality : a case where originality is not merely desirable but absolutely indispensable. And what sort of treatment does it meet with ? Nineteen times out of twenty, the problem is absolutely ignored—there is not a single step taken towards its solution. Either convenience alone is attended to, and the result is a "preaching-shed," disguised with a lot of vulgar finery ; or art is the one thing followed, and the product is a beautiful church with no fault except sheer unfitness for its purpose. The architect, perhaps, has introduced much novelty into the carving of the capitals ; his window-tracery is singular and noteworthy ; he has even brought from the Continent a tower and spire of extraordinary quaintness ; but where the design called aloud for original thought—in its general planning and construction—he has not an idea to give us. Much the same is it with other buildings for public assembly. How should they be treated, when above a very limited size, so as to be successful internally and externally ? There are our concert-rooms, like Exeter Hall and St. James's Hall ; if they are to be built without columns, how are we to treat them on the outside to make their wide roofs and awkward proportions endurable ? If, on the other hand, they are to be built with columns, where can these columns be least objectionably placed, and how, if they are of iron, can they be satisfactorily treated ? There are our theatres, the very centres of all that is architectually false and hideous. How can we make them honest in construction, simple and natural in design, fit for their intended use, and yet capable of yielding a sufficient return for the money invested in them ? For those who have the opportunity of dealing with it, here is another problem almost large enough by itself to satisfy one man's ambition. Then again there are our large railway stations : each of them, in their present state, enough by itself to spoil the finest view into which it intrudes : each of them, like those at Cannon-street, Charing Cross, and St. Pancras, so monstrous in its size, so astonishing in its shapeless deformity, that the mind can fix on nothing else while such an abortion is visible. Is it enough to dot over the walls of such a thing with bits of Gothic detail, and to leave its chaotic mass untouched ; to sing songs of triumph over the "wonderful success with which Mediæval principles have been applied to a railway terminus," when the very sight of it a mile off might have filled any Mediæval builder with horror? We are not complaining of Mr. Scott, who, in his department doubtless did what was possible at St. Pancras. What we maintain is, that general design, here as elsewhere, is the first thing that demands attention, though unfortunately the last thing that usually receives it. Is it really essential that these vast stations should be covered in one span ? or are the pleas put forward only meant to reconcile the public to a frightful eyesore, and the shareholders to a needless and wasteful expense ? Is not the fact at bottom this, that the average engineer cannot understand any greatness except that which is measurable in feet and inches, and thinks that to put up a wider roof than anybody else is to prove himself a greater man ? In this case it might be better for all parties to let him satisfy his ambition elsewhere ; to find him a piece of waste ground, and pay the cost of erecting on it one truss as wide as he could possibly contrive, and then, having immortalized himself in the only way he can conceive of, to let him act, in his practical works, with an eye to such trivial matters as economy and beauty. But however this may be, the general arrangement and construction of our larger railway stations presents one of the chief architectural difficulties of the time—one that is none the less truly architectural because it is seldom an architect whose business it is to grapple with it. We might go on enumerating, did space allow, many more types of modern building, each of which is a problem by itself. But a little reflection will furnish our readers with the list, and we therefore pass on to a wider question. What should be the general character and expression of our town architecture? What sort of grand combined effect can be got out of all the diverse designs which make up a modern city, or is there no such effect to be produced at all ? Is it possible for us all, working each in his own way, and for his own ends, to make up, notwithstanding, a perfect and harmonious whole, or must we go on, as now, in discord and confusion, each work injuring other works, and being injured by them ? We look abroad, at certain Mediæval cities, and at certain other newly built ones, and see that both, in different ways, have arrived at a grand combined result. The first have done it by picturesqueness and freedom—by bringing out the individuality of every separate building, and emphasizing it by adopting, in short, a vertical type for their street architecture. The second have done it by uniformity and stiffness—by suppressing individual character, by settling every height and width, and projection, according to unalterable rules, by taking up the horizontal principle and imposing it on everyone, by obliterating the individual houses, and caring only for the general mass of buildings. Is there any prospect, in England, of getting the latter system enforced by law ? Is it likely ever to be generally followed without such enforcement ? and, if not, is not the opposite system the only practicable, even if not the only desirable one ? Seeing that we cannot make our streets uniform, is not the only true course to make them picturesque ? To answer such questions as these is to do something towards solving the problem of how to produce harmony in our town architecture ; how, at last, to make our cities a grand whole filled with beautiful and harmonious parts, instead of a chaos of mutually destructive elements. And where they are answered, either one way or the other, a multitude of other questions suggest themselves. Suppose the uniform and horizontal type of street architecture is set aside as impossible for us. Suppose the opposite type, where every separate building is individualised, proves itself to be the only one on which we can gain any sort of combined result. The first step towards its adoption—towards the marking off of each design from the rest, can hardly fail to be the introduction of a certain verticality into the composition. The heavy cornice is the natural crowning member on the uniform and regular type ; when every house is made to range in height, a long unbroken line of such cornices binds the line together into what may be made one grand perspective. But the steep roof or gable is the most attractive finish on the alternative system ; standing out against the sky, it marks off, as nothing else can, where the strip of elevation which it belongs to begins and ends. In London, however, the Building Act binds us down, for warehouses, to a certain limit in pitch ; and in private houses, rooms wholly in the roof find little favour. It is, therefore, a matter for consideration whether steep roofs are essential to a picturesque street architecture, and especially to one developed on a Gothic basis ; whether we can overcome in some cases the practical objections to them, and in other cases, dispense with them altogether.

Descending further into detail, the modern architect is met by unsolved, or as yet but half-solved, problems at every step. We can here only indicate a few of them in the briefest manner. What, for instance, is he to make of wrought-iron girders ? May he use them, say, to carry the wall above a shop-front, and if so, is he to show them or conceal them ? If he shows them, how far can they be made to harmonise with the brick or stone arches in the rest of the elevation ? What, again, is he to make of iron roofs, and how is he to make their wiry lines agree in any way with the broad wall surfaces on which they rest ; and how is he to finish his ironwork—by painting, or bronzing, or enamelling—so as best to bring out its metallic character ? We could point to examples where something has been done towards answering each of these questions ; but in the average of recent work they scarcely seem to have had a thought. Then, in a very different department, how is the London architect to protect his work from London smoke ? Of course, if he feels that it is not worth protecting, and is satisfied with Bath stone and stock bricks, he escapes this problem. But, in the opposite case, what are the best materials to use, granite and marble, terra-cotta, or glazed bricks ? And how should his design be modified to suit each of them ? Next, having settled how to make his works smoke-proof, he may consider how to make them partially or wholly fire-proof. As far, at least, as the staircase is concerned, this ought to be done in every house—not, if we may trust Captain Shaw, with stone, but with some material that fire will no more break than burn. Then there are the questions of how to ventilate houses, how to warm them more thoroughly and less wastefully ; how to get the plumbers' work a little nearer perfection, and at least to keep the water-pipes from bursting every frost ; how to improve the design of a multitude of details, such as chimney-pieces, grates, and ironmongery ; how to use sash-windows and plate-glass with good effect in a Gothic building, or what to substitute for them ; how, in short, to adapt old styles to modern uses, and to bring into the field of architecture the waste and uncultivated deserts which now stretch all around and wait to be reclaimed. We do not pretend to have indicated a tithe of the problems which are pressing for attention. These, however, may be enough to show that there is no want of subjects just now for thought, and that the designer who wishes to be original is not obliged to concentrate his talents on the production of some new form of moulding or chamfer-stop.

ARCHITECTURAL PARIS.

THE interest felt by the whole civilised world during the siege of Paris was of a double character: it first touched the population, and next the city. From all Europe there came a cry of hope that the beautiful capital would be spared, apart from all questions of humanity; for, beyond a doubt, it was the most richly-built metropolis on the continent, and its architecture ranged through more than a thousand years of varying styles, from the age of Charlemagne to that of the Third Napoleon. It was feared that the storm of fire which had enveloped her walls would at length burst within the armed circle, and destroy monuments which could never be restored. To some extent, the havoc did penetrate inwards; but, happily, it was stayed before spreading far, and not a shell exploded through the grey roof of Notre Dame, or in the dim old cloisters of S. Germain l'Auxerrois. Paris is essentially a city of architecture, of palaces, churches, galleries, bridges, columns, triumphal arches, and fountains—the last not such as are flocked about in London by little boys and girls during the dog-days, but lofty masses of marble and bronze splendid with sculpture. The stranger, indeed, who visits it for the sake of studying—and the study is most useful—the difference between this former pride of France and the other great cities of Europe—London especially—almost wonders whence these French designers and stone-masons derived their courage and their genius. A careful perusal, so to speak, of the streets and squares and public edifices will inform him. In the Place Vendome, with its quadrangle of towering and stately houses, he will read the magnificence of the Fourteenth Louis; in the Rue de Rivoli, that of the First Napoleon; in the new Louvre, that of the Third; in the Tuileries, that of the First Francis; mingled with that of all succeeding sovereigns. The Palais Royal speaks of Richelieu, exactly as Hampton Court does of Wolsey; the Luxemburg of the Medicis and Italian pomp; the Tournalle of the bygone tournament days; and the Hotel of the Rohans—whose proud motto was, "I am not a king, I scorn to be a prince; I am a Rohan"—of that antique chivalry which has for ever passed away. But it is not precisely in these directions that we would, for a moment, glance. It is rather towards the works of the second—for, of course, he was only the second—Emperor of the Bonaparte dynasty. No monarch—not even the classic Augustus—ever bestowed so much thought and care upon the architectural embellishment of a great city. His junction of the Louvre with the Tuileries created a structure unparalled for extent and spendour; but the idea dated so far back as the reign of Henry IV. Napoleon, however, was first to take the work in hand, preserving, though enriching, the original style of ornament, upon which he employed a hundred and fifty artists, and sketching with his own pencil one of the noblest staircases in existence. The dimensions of this truly imperial pile, visible from every part of Paris, and commanding every part of it, may be imagined from the fact that, in one of those louvre-roofed towers, and the low range of buildings adjacent, sleep every night a thousand soldiers; and yet this is only an odd corner of the whole. Taking a general view, however, and comparing our own metropolis with that of France, we attain to a better notion of the French advance in these matters than by gazing at those glorious works of the architect, which we can never hope to emulate. A point of primal importance, well comprehended by the Third Napoleon, was the difficult task of opening new streets and communications through the quarters where the population were huddled together like bees in a hive, but with far less of order and regularity. It would not be easy to say whether old Paris or old London stood most in need of this reform; for if London required a free passage of air supplied, in consequence of the immensity of ground over which it extended, Paris required it from her habit of piling up floor upon floor, from eight to twelve stories high, rendering the streets cavernous and the lower apartments little better than so many sepulchres. There is much similarity between the position of the two cities. Both stretch along the banks of a river, and the chief communication is, consequently lateral to the water. Our streets in the transverse direction have been greatly improved; but in the lateral lines of traffic we have been scarcely able to cope with obstacles and expense. Thus, our great arteries, such as the Strand, Ludgate-hill, and Cheapside, notwithstanding the Thames Embankment, are almost impassable when the traffic is at its full. Through the instrumentality of Louis Philippe and Louis Napoleon the quays of the Seine have been opened, on both its banks, right through Paris. The river, in fact, is the main air-way of the French Capital. Yet this is not all. There stood, when the Emperor ascended his throne, in the quarter between the Rues S. Denis and S. Martin, a network of narrow lanes which it was difficult for even a foot passenger to thread. The imperial architect, with his Boulevard de Strasbourg, cut through the maze from end to end, and opened a superb prospect where before there had only been filth, dilapidation, and squalor. When, however, we speak of architecture in connection with the self-bewailing city, we do not restrict the term to the mere elevations, façades, and profiles of the majestic metropolis. We would even include within the phrase sewerage, water-supply, and fortifications—three subjects well worthy to be touched upon just now. It is often said that we, with our main-drainage system, have inaugurated a new era. Nothing could be more untrue. With the ancients the aqueducts and cloacæ are as old as the walls of their proudest towers, and more durable. The further we travel south the greater is the desire for water. Paris, years ago, before we had thought of them, enjoyed these characteristics of latitudes less northern than our own—public fountains. She had two thousand of them so far back as fourteen years ago; but her abundance was in the streets and not in the houses. So with her sewage. Down to a very recent period the only sewers of nineteen twentieths of Paris ran uncovered through the middle of the street. All this, or nearly all this, is now changed, and a wonderful organisation has been built below, upon a principle which the French describe as canalisation. An idea of this is given in a regulation under the hand of Baron Haussmann, late Prefect of the Seine:—"Every principal line of sewer shall be provided with a gallery, having a railroad. Galleries of less dimensions, but equally furnished with rails, and permitting the circulation of waggons and workmen, will be established in the secondary sewers. A gallery of small section, large enough for the passage of barrows, will go round the foundation of each block of houses on every side." But we will ascend again, and glance abroad at architectural Paris as represented by her monuments and streets. It may be admitted that most of the splendour is comparatively new. There are no trophies of magnificent civic aristocracies, such as are found in Italy; none of the higher order of burgher life and independence, such as are found in the Netherlands; no sacred corners, like Westminster Abbey, with great histories written on their walls. The Sainte Chapelle is perfect in its way, but Notre Dame is very poor, considering that it sprang from that century of glories, the Fourteenth. Paris wants steeples and pinnacle, and its churches appear to have been erected in a spirit half-Pagan and half-Puritan. Voltaire once compared it to "the most miserable village in Westphalia." Alfieri could find little to descant upon except the poverty of its public structures. There was no pavement until the royal stomach of Philip Augustus was turned by the odours produced by a waggon ploughing up the mud; yet now, we behold, notwithstanding bombardments and havoc, the stateliest city out of all comparison in Europe. The genius which wrought the change was the genius of architecture. We except the University and the Hotel de Cluny—the latter an exquisite Gothic specimen; and we regret the palaces of the bygone times, with their cylindrical towers and their extinguisher roofs, which must have been so picturesque. The tower of Catherine de Medici's Hotel, still standing alone, suggests what "the finest private dwelling of its age" was when entire. Regrets, however, are soon lost amid realities. New Paris, the centre of a brilliant kingdom, with its great lines of railway communication, has outgrown the city of even our memory ten times more rapidly than it outgrew the old boundary of the Romans in their palisaded island. The Deux Centre has been cleared out; whole quarters of the city of Philip le Bel have been swept away; and Paris gives, in her beauty and richness of perspective, a lesson to the world. What, however, of that other architecture to which we have alluded—the architecture which converted her into the hugest fortress that Europe ever saw, and yet was powerless to resist a besieger? Not much need be said about it. The results of the war have proved that it was a gigantic mistake, though the works were admirably constructed on the modern principle. Nobody, indeed, was ever awed by their aspect. The unmilitary tourist, who expected to see frowning battlements and majestic towers, saw only verdant slopes and grassy mounds of slight elevation; still, the walls, though sunk, were lofty; the moats surpassed all anticipations. Of course, since the invention of cannon, the embattled towers of the middle ages have fallen into disuse; they are now either restored, or imitated, or left to moulder in ruins as objects of picturesque attraction. Even when gunnery was in its infancy, and the details of its cumbrous machinery were of the rudest description, it was often enough to place a few pieces of ordnance in battery against a walled town to secure its surrender, so sure were the thickest walls to crumble when under the shock of their fire. Still, it was for a long time necessary to have high walls; since, but for such an obstacle, an enterprising besieger might avail himself of the darkness of night to penetrate at some unguarded point; but it became a problem how to screen them from the artillery of the foe, until at least, he arrived quite close. Modern science solved the problem, and ramparts became earthworks, faced with masonry, with parapets 20ft. thick. Paris was thus defended; but the ancient French maxim held good "place assiegée, place prise"; a town attacked is a town taken. We may leave the fortifications; they have been turned against their mother. Returning to the architectural aspect of Paris at the present day, we have to note a peculiar element in the building and decoration of private dwellings by people who have not long known what it is to be wealthy. We frequently refer to Parisian taste, but it is not uniformly shown in the instruction given by fortunate speculators to their architects. A keen eye, roving over the new city, white as the Alban capital in ages gone, will detect in colonades, corridors, and balustraded recesses—very pretty in their way—a little bit of Doric, a little Ionic—the French are not, as a rule, fond of the Corinthian order—a tint from Persia or Assyria, an Etruscan group, a panelling of alabaster surmounted by the most beautiful of all ornamental devices—excepting the honeysuckle, or alternate bud and flower—the guilloche, and a plafond in the style of Louis XV. —all naughtiness, nakedness and riot. Therefore, glittering as the general effect may be Paris is not, in the strict sense of the term, a city architecturally-built; it belongs to a country which never had a "school" of its own, but revels in an eclectic luxury, mosaic-

ing itself from all lands and all eras—now pilgrimaging to the lone white columns on Egæan headlands—now adapting from the mystic interior of Amron or Ebn Touloun. For all this the whole civilized world must rejoice that the city of beauty and grace was not doomed to perish beneath the Gothic fire.

ARCHITECTURAL ASSOCIATION.

At the ordinary general meeting on Friday evening last, Mr. T. H. Watson, president, occupied the chair. Several new members having been elected, the best thanks of the Association were tendered to Lieut.-Colonel Scott for his kindness in permitting a number of the members to visit the new Science Schools and the new courts at the South Kensington Museum, and to Mr. Gilbert R. Redgrave, for kindly conducting the members over the works. It was also announced that the particulars of the prizes offered by Mr. Edward W. Godwin would shortly be published. Mr. Watson informed the meeting that Professor T. Hayter Lewis had been requested to act on the Committee for Architecture in the International Exhibition of 1871. He had at first declined, on account of ill-health, but having now recovered, he had on the request being repeated, consented to act.

Mr. F. J. Francis, F.R.I.B.A., then read the following paper :—

NOTES ON THE RECENT WORKS AT ALL-HALLOWS' CHURCH, LOMBARD-STREET, WITH REMARKS ON SIR CHRISTOPHER WREN'S CHURCHES.

I purpose to confine myself first to a brief description of All Hallows', Lombard-street, following it up by some remarks upon the leading principles of design observable in the more important of Wren's London churches, and then contrasting them with the general principles governing the design of buildings of the Pointed style. But, first of all, we ought to pay a passing tribute to the manifold gifts which were centred in this remarkable man. Without any disparagement to the many excellent men of proved ability whose architectural works are an honour to the present age, it must be admitted that few could compete with Sir Christopher Wren, whose youth was passed in abstruse and philosophical research, and who was celebrated for his scientific attainments before he set his mark on his generation by his architectural genius. In his childhood of weak bodily constitution, he had a most precocious mind, and it displayed itself not in poetic fancy and feeling, but in the abstruser paths of science and philosophy. What will the young architects whom I see before me say when I tell them that at the age of thirteen it is recorded of Wren that he had invented an astronomical instrument, a pneumatic engine, and other triumphs of mechanical skill ? No wonder that with these credentials, presenting himself at our ancient seat of learning, the University of Oxford, he attracted the notice of the Savilian Professor of Astronomy, and that at the age of twenty-one he was elected a Fellow of All Souls' College. At the age of twenty-four he was known to the learned of all Europe by his various theories and inventions; but his previous pursuits in no way prepared the world for that efflorescence of architectural genius by the results of which his name is now chiefly remembered. And surely it says something for the elevating nature of our art that, having traversed the sublime mysteries of astronomy, mathematics, and scientific mechanics, Wren should have found a fitting field for his far-reaching intellect in the study and practice of architecture. He was hardly aware of the mine of mental wealth which laid unwrought within him till the opportunity occurred for its exercise. Step by step his majestic views unfolded themselves, and the explanation is afforded by that true inscription placed beneath the statue of Newton in the ante-chapel of Trinity College, Cambridge, which speaks of him, as of Sir Christopher, as one *Qui genus humanum ingenio superavit* (Who in understanding excelleth the human race?). We shall hereafter venture to estimate, though diffidently, the real merit of design pervading his ecclesiastical structures; but it will be appropriate, as carrying out the object of this paper, to pass on to a description of one of the many churches which, after the Great Fire of London, sprang up under the direction of this Surveyor General of Public Buildings.

All Hallows', Lombard-street, was erected about the year 1674. It stands on the site of an earlier church. The plan, as in the majority of Wren's churches, is very simple—a parallelogram 72ft. long, 52ft. wide, and 33ft. high. A massive tower, possessing no distinctive merit, stands at the south-west angle, in a line with which, northward, is a vestibule or ante-chapel with a groined ceiling springing from a detached pier—certainly not the least effective portion of the interior. At the east-end is a chancel recess with a segmental roof, and about 12ft. deep ; and the east wall is adorned with a highly enriched screen of the Composite order, rising to a height of nearly 30ft, with twisted and enriched shafts, and with deeply sunk panels and pedimented heads—the details somewhat incongruous, yet characteristic of Sir Christopher Wren's decorative manner. At the west end are two Corinthian porches of elaborate design, upon which the architect appears to have bestowed unusual care. The ceiling is flat, with a cove on the four sides. The north and south windows (which are large, measuring 16ft. by 6ft.) are carried up to a height requiring the introduction of groins to combine with the design of the ceiling. The pulpit and pewing were very characteristic, not of Wren only, but of the state of the Church of England at that period. The former is highly enriched, remarkably well placed for sound, and surmounted by a massive sounding-board. Altogether we felt it would be sacrilege to touch this part of the interior, and beyond lowering the shafts to assimilate the pulpit with the reduced height of the seats, this detail remains as Sir Christopher Wren left it. The pew-framing had considerable foliated enrichment, all of which has been preserved, but its outline was stiff and formal. The backs were high and upright, the doors were furnished with locks, and everything seemed calculated for an exclusive, and I may add, a somnolent worship. A range of pews was placed against the north and south walls, somewhat elevated above the aisles, and enabling the occupants to command, by a sort of crossfire, the countenances of their fellow-worshippers, more reverently placed facing the east. These we had no hesitation in removing, appropriating the area of the destroyed seats to the formation of suitable passages of entrance to the new benches. No doubt when the church was erected there was a fair margin of ground round its sacred precincts. At the south was its churchyard, opening into Lombard-street. Its east-end faced Gracechurch-street, while its west-end abutted upon a quiet passage away from the din of City traffic. But its present aspect is far different. The requirements of commercial activity, joined with ecclesiastical supineness, or perhaps rapacity, have so blocked the surrounding area by secular buildings that the church's existence is hardly guessed by the thousands who day by day visit the charmed centre of City activity within which it stands. Public dining-rooms now abut both upon its eastern and western walls. Upon part of the churchyard stands a building where trousers are sold at thirteen shillings per pair, and a row of commercial chambers casts its shadows upon the northern side at a distance of about 8ft. I ought to mention that Sir C. Wren's interior was not suffered to remain entirely untouched. A gallery, certainly not part of the original structure, stretched across the western end ; it contained the organ and concealed from view the west window, while the intrusion of the tower into the south-west angle of the building was supported by a corresponding sham projection on the north, where was formed a very inconvenient room, approached by a cumbrous staircase concealing the groining and ruining the effect of the interior. Under the operation of the Union of Benefices Act, the parish of All Hallows' was united with S. Benet's, Gracechurch-street and S. Leonard's, Eastcheap. S. Benet's Church, another of the productions of Wren, was taken down, the site was sold, and four large shops now stand on part of its site. With the money thus obtained (I believe about £22,000), it was provided that a church should be built and endowed in some destitute parish at the east-end of London, and also that, at a cost of £1,000, All Hallows' church should be repaired, restored, and decorated, so as to form a fitting church for the use of the three united parishes. The works have been carried out successfully, and the church, after having been for about nine months in the hands of the builders, was opened a few weeks since by the Bishop of London, in presence of the Lord Mayor and Sheriffs. The constructive features of Sir C. Wren's architecture have been carefully preserved, and especially, I may say, we set our face against so organic an interference with the simplicity of Wren's windows as would result from the introduction of central dividing columns and arches. I cannot deny the tastelessness observable in too many of these large windows ; but they were emphatically the manner of the master, and in my opinion their character should remain unaltered. The west galleries have been removed, as also the room at the north-west corner, throwing open the fine vestibule, the west window, the detached pilaster, and the groined ceiling. The old pewing has been replaced by low oak benches, with bench ends of a design suitable to the rest of the wood-work. All the old wood carving has been worked in where practicable. The seats, with the exception of the choir stalls, uniformly face the east. The organ stands on the floor of the church at the south-east corner. The case is remarkable for its beauty of design and elaborate enrichment. In its present position these features are much better appreciated than when the instrument was placed in the gallery recess. The pavement throughout has been laid with encaustic tiles, the pattern increasing in variety and the number of figured tiles as the east is approached. Within the altar space there is a free sprinkling of glazed tiles. The altar rail is of brass, with foliated standards and a telescope slide. The wall and ceiling decorations are very effective in character. On the ceiling the corner medallions represent the Evangelists, the central subject being a figure of Our Lord in Glory, seated on His throne. The more salient parts of the cornice mouldings are brought out in gold and colour. The faces of the groins under the main ceiling have foliated enrichments, with medallions representing at the east and west ends the four Great Prophets. The side medallions contain representations of patriarchs and kings. Arabesque decoration is carried round the window arches and above the wood panelling on either side of the church. There is an unusual amount of stained glass, and of a very meritorious character, executed by Mr. Alexander Gibbs, by whom also the wall and ceiling decorations have been carried out. The window at the north side of the chancel represents the Marriage of Cana in Galilee. On the south side of the church, commencing from the organ, the subjects of the four windows are—(1) Christ sitting in the Temple; (2) Christ Healing the Blind; (3) the Good Samaritan ; and (4) the Three Marys at the Sepulchre. The west window contains a striking representation of the Crucifixion. On the north side, commencing from the vestry, the subjects of four windows are—(1) the Wise Men's Offering ; (2) Christ raising the Widow's Son ; (3) S. Peter Walking on the Sea ; and (4) the Entombment. Considerable pains have been taken with the decoration of the reredos, which, as I have already observed, is very handsome and highly characteristic. The principal lines have been relieved with gold, as also the shafts and capitals ; and the monotony of the dark colour of the wood has been further destroyed by painting out the Ten Commandments, and substituting in the central panels over the altar two pictures in oils, one representing Christ crowned with Thorns, and the other Christ bearing the Cross. Sacramental texts occupy the side panels, and on the return sides of the panelling, north and south, are painted on a light ground the Creed, the Lord's Prayer, and the Ten Commandments. I should like again to call attention to the fine original porches at the western end, and to the peculiar gateway formerly placed at the entrance of the passage out of Lombard-street, now fixed, on account of its archæological interest, in the vestibule under the tower.

I need not further occupy your time in detailed description of this church, but it remains that I should supplement what I have said by some remarks upon the main features of Wren's churches, and what appears to constitute at once their special strength and weakness. The noble cathedral of S. Paul's, itself worthy of a separate and distinct paper, must not be passed without remark. It was curious that at the time of the birth of Wren, Bernini was employed in the completion of S. Peter's at Rome, the great rival of S. Paul's in skilful construction and mechanical execution. Wren accomplished S. Paul's alone in the space of about thirty-five years, while S. Peter's was the work of twenty architects, supported by the treasure of the Christian world, and by the protection and under the pontificate of nineteen successive Popes. Whether the original design of the architect of S. Paul's would have been more effective in its result than the present structure,

it is not for me to determine; but in one respect the original conception falls short of the realised design, inasmuch as in the former there is no space for a collected congregation except in the circular area beneath the dome, which could not be fitted up for such purpose without being further enclosed, whereby also in other respects the grandeur of the *ensemble*, as it shows itself in the plan, would have been greatly impaired. The first stone of the cathedral was laid in 1675, and the last stone in the summit of the lantern was laid by the architect's son in 1710. Taken altogether, as has been justly observed, "The present S. Paul's is a truly glorious work, its cupola matchless in beauty, satisfying the judgment, if not entrancing the taste of the spectator." Yet all-noble though it be, the fabric will not bear to be scrutinised in the spirit of captious criticism, and of late years serious attempts have been made to derogate from its excellence. I fear it cannot be denied that the real form and construction of the building are masked, the upper order of the side elevations being merely a screen concealing the buttresses and clerestory windows of the nave, and that the same is in a great measure the case with the cupola or dome, the external dome being much loftier than the inner one. All this may be true, and yet the merit of the wonderful structure remains almost without abatement. For external congruity of design, and for grandeur and solemnity of internal effect, it takes the very highest rank among the Roman models at the period of or subsequent to the Reformation. Still it must be admitted that on entering this noble pile—and of course in a much greater degree in visiting the minor churches of this great master—there is a feeling of intense disappointment. How little has been done in the Metropolitan Cathedral to wake into life the dry bones of that magnificent though melancholy shrine? With how sparing a hand have the sister art of painting, the refined forms of mural decoration, and the glowing pageantry of stained glass been introduced to relieve the interior from its chill and depressing baldness? It remains a monument indeed of Classic accuracy and mathematical ingenuity of construction, but hardly a living temple, instinct with the furtherance of the religious element, and fraught with reverential associations.

(To be concluded in our next.)

NEW ELEMENTS OF HAND-RAILING.*

(Continued from page 126.)

PLATE 23. — QUARTER-CIRCLE STAIRS HAVING FIVE WINDERS AND LANDING WITH ONE SQUARE STEP.

FIGURE 1 shows the ground plan. The rail on right going up stairs. The tangents form the right angle A B C.

Fig. 2 shows tangents, winders, and square steps unfolded.

The under side of level rail on the landing is raised to suit long balnster on square step.

The wreath over winders has unequal pitches: its upper part being T N; the lower, T L; its height, R L.

To find a direction for ordinate. Extend L T, cutting at P, which gives P R. Transfer this to extended side of square, Fig. 3, where corresponding letters are shown.

Let square equal that on plan. Draw ordinate. Make seat square with it. Let height equal that on right. Then draw pitch and construct mould as usual.

Tangents L, T, N, to be correct, must equal corresponding letters on pitch, Fig. 2.

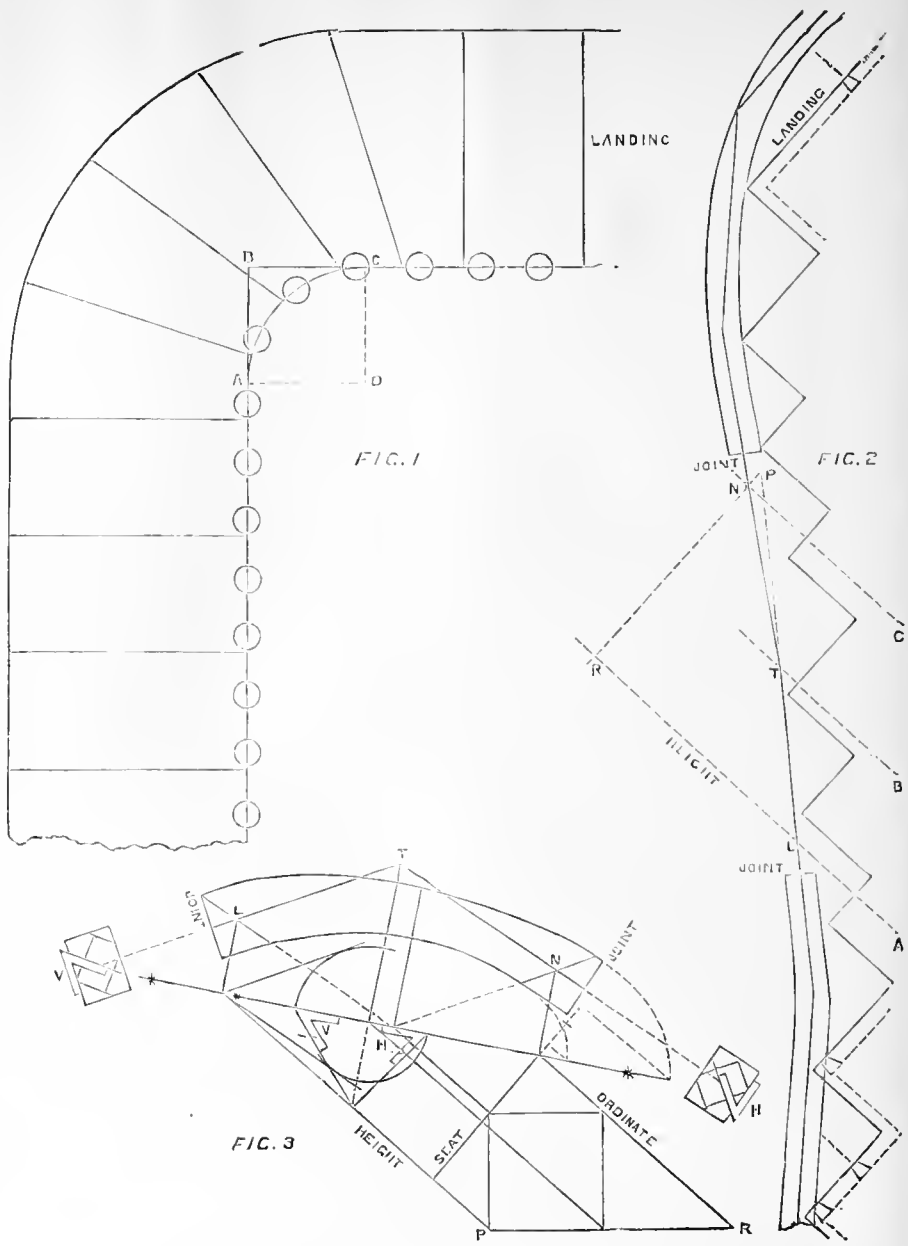
Square sections show joints.

Stock of bevel H and that of V are on the surface of plank. The blades, in all cases, pass through half the width and half the thickness of rail. In other words, the tangents on mould being square across the joints, then half the thickness of plank marked gives a centre through which the bevels pass.

The accuracy of work depends entirely on the proper application of bevels, and the manner in which the joints are made. An error in either renders it impossible to have a wreath stand correctly over its plan. This has been already remarked, and should be constantly kept in mind.

Nearly all the drawings are to a scale of inch and half to the foot, which gives the opportunity of clearly showing the meaning and intention of every line, particular pains having been taken, to make each plate its own interpreter, not depending solely on letter-press description.

* This series of articles is a reproduction of ROBERT RIDDELL'S work on the subject, published in Philadelphia, and by Trübner and Co., London.



NEW ELEMENTS OF HAND-RAILING.—PLATE XXIII.

LIMES AND CEMENTS.

LIEUT.-COL. SCOTT, R.E., gave the fourth, and concluding lecture of this series, on Monday evening last, at the rooms of the Architectural Association. Having recapitulated the subjects of the three previous lectures, Col. Scott began by pointing out in what way the suitability or otherwise of limestones for making limes and cements for various purposes, could be tested, so that if any member present had to carry out a work in a foreign country in which there were no manufacturers of lime he would be able to select materials fit for his purpose, assuming that such an one had a sufficient knowledge of mineralogy to be able to distinguish a limestone from any other stone. If the application of acid to a limestone entirely dissolved it and left no residue, the material, when burnt, would only give a pure lime, most unfitted for building purposes; if, on the other hand, it left a residuum of very fine clay, quite impalpable to the touch, it was probably capable of being manufactured into a more or less hydraulic lime. Muriatic acid or nitric acid might be used, but muriatic acid was preferable on the score of doing less damage to one's clothes than nitric acid. Sulphuric acid might also be used, but this test was more difficult of application and gave less satisfactory results. Muriatic acid was, all things considered, the best for this purpose. When the stone was burnt and it was desired to know what results a mortar made from it would give, a good plan was to take a small quantity of it in a pounded state, and to add muriatic acid to it. The acid dissolved out all the iron, alumina, and lime it contained, but left the silex as a somewhat gelatinous mass. By means of filtration the silex may be separated from the other matters which are in solution. In the clear-filtered solution there might be present chloride of iron, chloride of aluminium, chloride of calcium, a little chloride of magnesium, chlorides of the alkalies, and perhaps a little manganese. As soon as the liquid has passed away from the gelatinous silex which remains on the filter, the residuum, after being well washed with a washing-bottle, may be dried, calcined in a platinum crucible, weighed, and estimated. The next step is to obtain a substance which will lay hold of the chlorides of iron and alumina in solution. The addition of ammonia effects this by the neutralisation of the acid, and a somewhat dense precipitate is thrown down. By means of another filtering operation, the iron and alumina can be separated, and another clear solution will be obtained, consisting of chloride of calcium, and, perhaps, chloride of magnesium. If magnesia is present in a limestone it will give a better hydraulic lime than that obtained from pure limestones. The American hydraulic limes contain a large quantity of magnesia, but the lecturer was not aware that any of the hydraulic limes of this country contained that substance in any great degree. By

treating the clear fluid obtained from the second filtration with oxalate of ammonia, the lime it contained was thrown down as a white precipitate, which might in turn be separated by a third filtering operation and estimated as before. In making an analysis of an hydraulic limestone, the best method is to separate first the clay from it, and then the iron and alumina. Indeed, this is really all that is practically necessary. Supposing that the silex, iron, and alumina were large in quantity, such a limestone, though unfitted for use by itself, could be used very well as a puzzolana, which, if very intimately mixed with a pure lime, will impart hydraulic properties to it. The puzzolanas imported from Italy some years back for this purpose, and the trass or terras from Holland, were rich in silex, iron, alumina, and magnesia: but we in this country might have done equally well, or better, if we had made use of many of the beds of stone, shales, &c., of this country, which, if treated properly, would have given better puzzolanas than those imported at great expense from abroad. The lecturer next spoke of the lax way in which limes and mortars were specified by architects and others. He said that a perusal of the specifications which had been published of some of the great works of this country would show that some particular lime had been specified, as, for instance, "Halling or Merstham lime," as if both these varieties were identical; "lias lime," too, was frequently specified, without naming the locality from which it should come. He observed that there were so many gradations of quality of each denomination or variety of lime, that he thought it would be best for architects (if they could only be persuaded to do so) to specify the percentage of silica they required in a lime rather than the particular district from which the lime was to be procured; the builder could then select the quarry accordingly. Colonel Scott said that he tried many years ago to induce the War Office to adopt this plan of specifying lime, and was so far successful that in one or two works the principle was acted upon; but he believed that it had now fallen into disuse. Speaking of the action of the atmosphere on limes, the lecturer said that the injurious effect of the exposure of limes to the air was very much over-rated. Such exposure turned it into a hydrate of lime, but it had in reality undergone very little change, except that it would not heat quite so rapidly when slaked, and therefore its power of throwing abroad hard particles was lessened. He remarked that the atmosphere was only doing gradually that which would eventually be done when the lime was slaked previous to its use for mortar. After a time the water absorbed by the lime, however, began to be expelled by the carbonic acid gas of the atmosphere, though this was a slow process, owing to the small amount of carbonic acid present in the air. In buying lime in bags it behoved the purchaser to be quite certain that the lime had not been exposed for a long time to the atmosphere, for if it had he would of course get less for his money, owing to its expansion in bulk by the action of the moisture of the air, which was not so easy of detection in the bag as in the lump. If pure chalk lime was exposed to the air for fourteen days, and the air allowed to attack it freely, Pasley found that while it increased 8 per cent. in weight it increased 44 per cent. in volume; after forty-two day's exposure it increased 15 per cent. in weight, and 101 per cent. in volume. If it is wished to ascertain the quantity of moisture present in any specimen of lime, it is done readily and simply by taking a glass tube, putting a little lime into the bottom, and exposing it to a red heat, when the water would easily be driven off into a tube containing pieces of chloride of calcium, which would absorb the water. By weighing this latter tube before and after the operation the quantity of water is readily determined. But a more practical, if not so exact a method, was to add a little acid to the lime, and to observe whether the effervescence was very violent or not after stirring it round. Weight, the lecturer observed, is not much of a test for limes, though it was much used as a test for Portland cement; but weight was not really a test for all cements—it was not a reliable test for Roman, Medina, Atkinson's, or any of the quick-setting cements. However, there was a good test for these very easy of application, viz., merely mixing a little of the cement with water, and observing whether or not it set both quickly and hardly. But such cements should not be condemned too hastily, as the burning of them, particularly in the case of Roman cement, required to be done to a very great nicety; and it might happen, without any great amount of carelessness on the part of the manufacturer, that the material might answer fairly well in practice, though apparently sluggish in taking its set. It was constantly said now that Roman cement has very much deteriorated in quality of late years, and it was commonly supposed to be very much adulterated. Now Colonel Scott said that he had examined two or three hundred specimens of Roman cement, and had never found one which might be said to be adulterated. Very frequently it got exposed to the action of the atmosphere, and so got injured in that way. He thought that Roman cement is now just as good as ever it was, but people, from the use of Portland cement, expected too great results from Roman cement. The lecturer then proceeded to describe the manufacture of Portland cement, after which he touched upon some of the points to be borne in mind by the purchaser of that article. He said that because it contracted in bulk the more it was burnt, if it was bought under-burnt the buyer was of course getting less for his money than he would were it burnt to the requisite degree. Engineers knew this very well, and therefore always bought their cement by weight. It was against the manufacturer's interest to burn it to too hard and flinty a state, for in that condition it caused great wear and tear of his grinding machinery. Again, if the burning was not carried very far he saved in fuel. There were, therefore, three reasons why, unless cement was bought by weight, the liability was incurred of obtaining an inferior article. Referring to the test of strength for Portland cement, the lecturer said that the manufacturer might arrive at strength in one or two ways. In proportion as it was reduced to a fine state of division by grinding a better result was obtained. Many manufacturers after the material is ground do not "bag" it at once, but place it in bins for a time, and the bags are subsequently filled from the contents of these bins after they have been thoroughly admixed. By this means the under-burnt limey particles become air-slaked, and the injury they might do to the material is avoided. Portland cement, in fact, is improved rather than otherwise by keeping and exposure to the air. Perfect manipulation and admixture of the constituents will give greater strength. There was another, but a very dangerous way, in which strength could be arrived at, and that consisted in reducing the quantity of clay. The effect of this might be got over in some measure by exposure to the atmosphere; but where the quantity of clay was very small the Portland cement would always be a very treacherous material. The lecturer said he had known specimens of Portland cement which contained no more than 18 per cent. of silex to set very well at first, and to last well for some time, but which eventually played great pranks, and occasioned many serious accidents. He thought that instead of looking for such a very high test of strength for Portland cement he would rather take a cement of less apparent strength but containing more silica. The lecturer next proceeded to speak of the mixing of limes and cements for use, and the proportions of sand best adapted for different varieties of limes, as dwelt on at great length in the previous lecture. In conclusion, Col. Scott insisted upon the necessity, if good work was desired, of using wet bricks and stiff mortar, and strongly condemned the practice of "grouting." He said a French architect, M. Vicat, gives the English credit for their bad mortar for the following reason, that our builders for the most part have in view only the extent of a 99 years' lease, and so proportion their various materials that the whole structure shall fail together at the expiration of the 99th year.

Mr. R. Phene Spiers, in proposing a vote of thanks to Lieut.-Col. Scott, expressed the great indebtedness of the Association to him for delivering such a valuable course, and remarked that the lecturer had studied the question with that peculiar energy which seemed to characterise the engineering profession in considering the subject of materials.

The motion was seconded by Mr. T. Marr Johnson, and supported by Mr. Quilter, and unanimously carried.

Col. Scott, in acknowledging the compliment, said that probably the reason why the Royal Engineers studied the nature of materials more carefully than architects was that many of their structures were built to be fired at, but architects fortunately had not to build with such an object in view (laughter.)

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

Dr. G. G. Zerffi delivered the twentieth lecture of his course on the above subject, in the lecture theatre, South Kensington Museum, on Tuesday afternoon last. Continuing the list of the works of Alkemenes, the lecturer said that a head of Juno in the Villa Ludovisi, though thought to be only a copy, was one of the loveliest compositions. It united stern dignity with the inexpressible grace of womanly beauty; imperishable youth bloomed on the delicately-rounded cheeks, and the whole face expressed a spiritualised divine love. Both this artist and Polykletus had not represented Juno merely as a beautiful woman. She had been with them the symbol of the holiest moral force working in humanity, and the emblem of the only possible basis of human society—marriage. The artists of ancient Greece, like those of modern times on the continent, had had schools. Here the younger artists had been allowed to work and reap the benefit of occasional advice from the master. The school of Phidias had produced Agoracritos, whose works had often been mistaken for those of the great artist himself, Kolates, Pœonios, and many others. Polykletus had had eighteen pupils, amongst whom was Naukides, who had sculptured a disc-thrower. The best copy of this statue was in the Vatican at Rome. The figure held the disc in the left hand, on the point of transferring it to the right, and then throwing it. Thus two prospective movements had to be pourtrayed. The head was, undeniably, superior to that of the similar statue by Myron (which represented one movement only), but the expression of the action was less characteristic. The most important monument of this period, and of the school of Argolis, was the frieze of a temple of Apollo, found in 1812 at Bassæ, and now in the British Museum. It represented a combat between Kentaurs and Amazons. Victory and defeat were expressed in striking groups. The composition was realistic, and passion predominated—the nude executed with exquisite truthfulness, but rather heavy, and the movements too sudden and violent. The great influence the state of the country in which an artist lives had on his works could be traced in this production. At this time Greece had been plunged in civil war, and her artists no longer worked with a feeling of security; the chisel trembled in their hands; they saw prophetically the downfall of their art, and the balance between beauty and morality had been lost. In considering, therefore, the third period of Greek sculpture (400-323 B.C.) we should see that in politics, in poetry, in science, and in art, a corresponding change had taken place. Simplicity and grandeur of thought had given way to sophistry and elegant writing; the idea began to be sacrificed to the form; in the place of Aristides stood Alcibiades; Sophocles had been replaced by Euripides, and Socrates succeeded by Plato. The sublime works of Phidias also had been superseded by the charming compositions of Praxiteles. To detach an isolated phenomenon in the development of the national and intellectual life of a people, therefore, would lead us only to a knowledge of single effects, but never to a correct appreciation of the causes that engendered them. The whole tone of society and the very mode of thinking, had become changed in Greece. Public buildings began to be neglected, and private edifices of a costly nature had arisen. The national spirit which had aspired only for all had dwindled into individual egotism, and artists became compelled to execute works to please the fancy of the purchaser. There still remained so large an amount of vitality in Greek art that it had been even then able to elevate particular forms into general conceptions of beauty; but these forms were no longer sublime and dignified. Passion, artificial pathos, and an excited and restless expression of the mind had become more prevalent. The divine characters of Phidias had vanished, and the divinities became endowed with a certain sensuality, losing thus their spiritual character. The outer forms had become more perfect, and the deepest feelings of excited passionate humanity trembled through the stone images. Art, instead of being objective, had become subjective. The divinity of love had no longer been the generalisation of love in mankind, but the expression of that feeling in one particular form. In illustration of this, we had an Eirene (peace) with Pluto (riches) in her arms (about 370 B.C.), by Kephisodotus, the elder, who had been probably the father of Praxiteles. It was, in fact, an allegory, grown out of a desire to

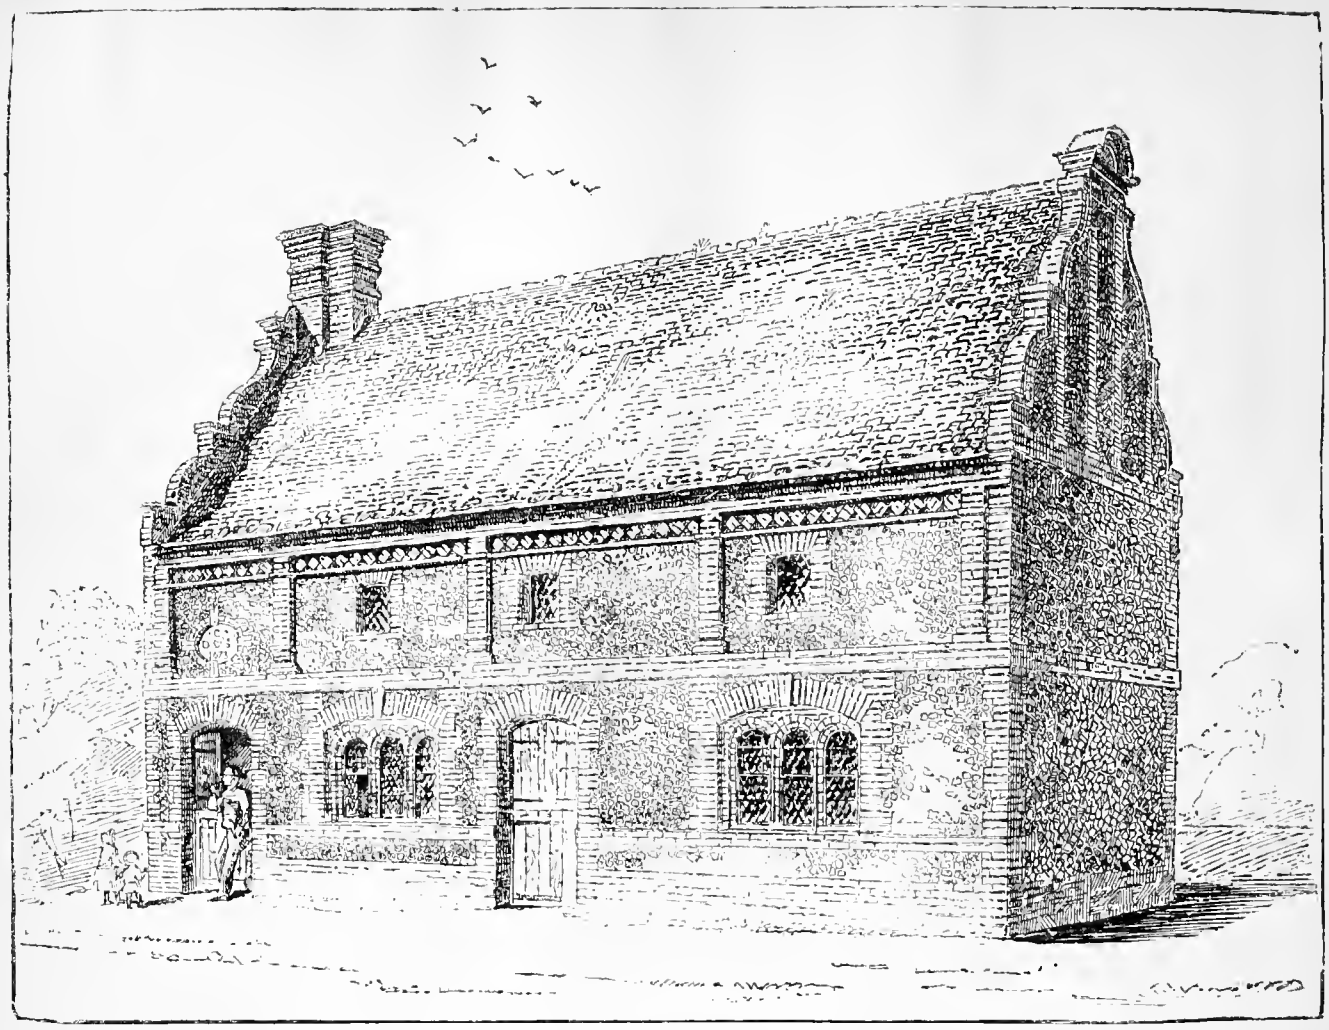


Fig. 1.—Ancient Brick and Flint Cottage at Broadstairs. (See p. 167.)

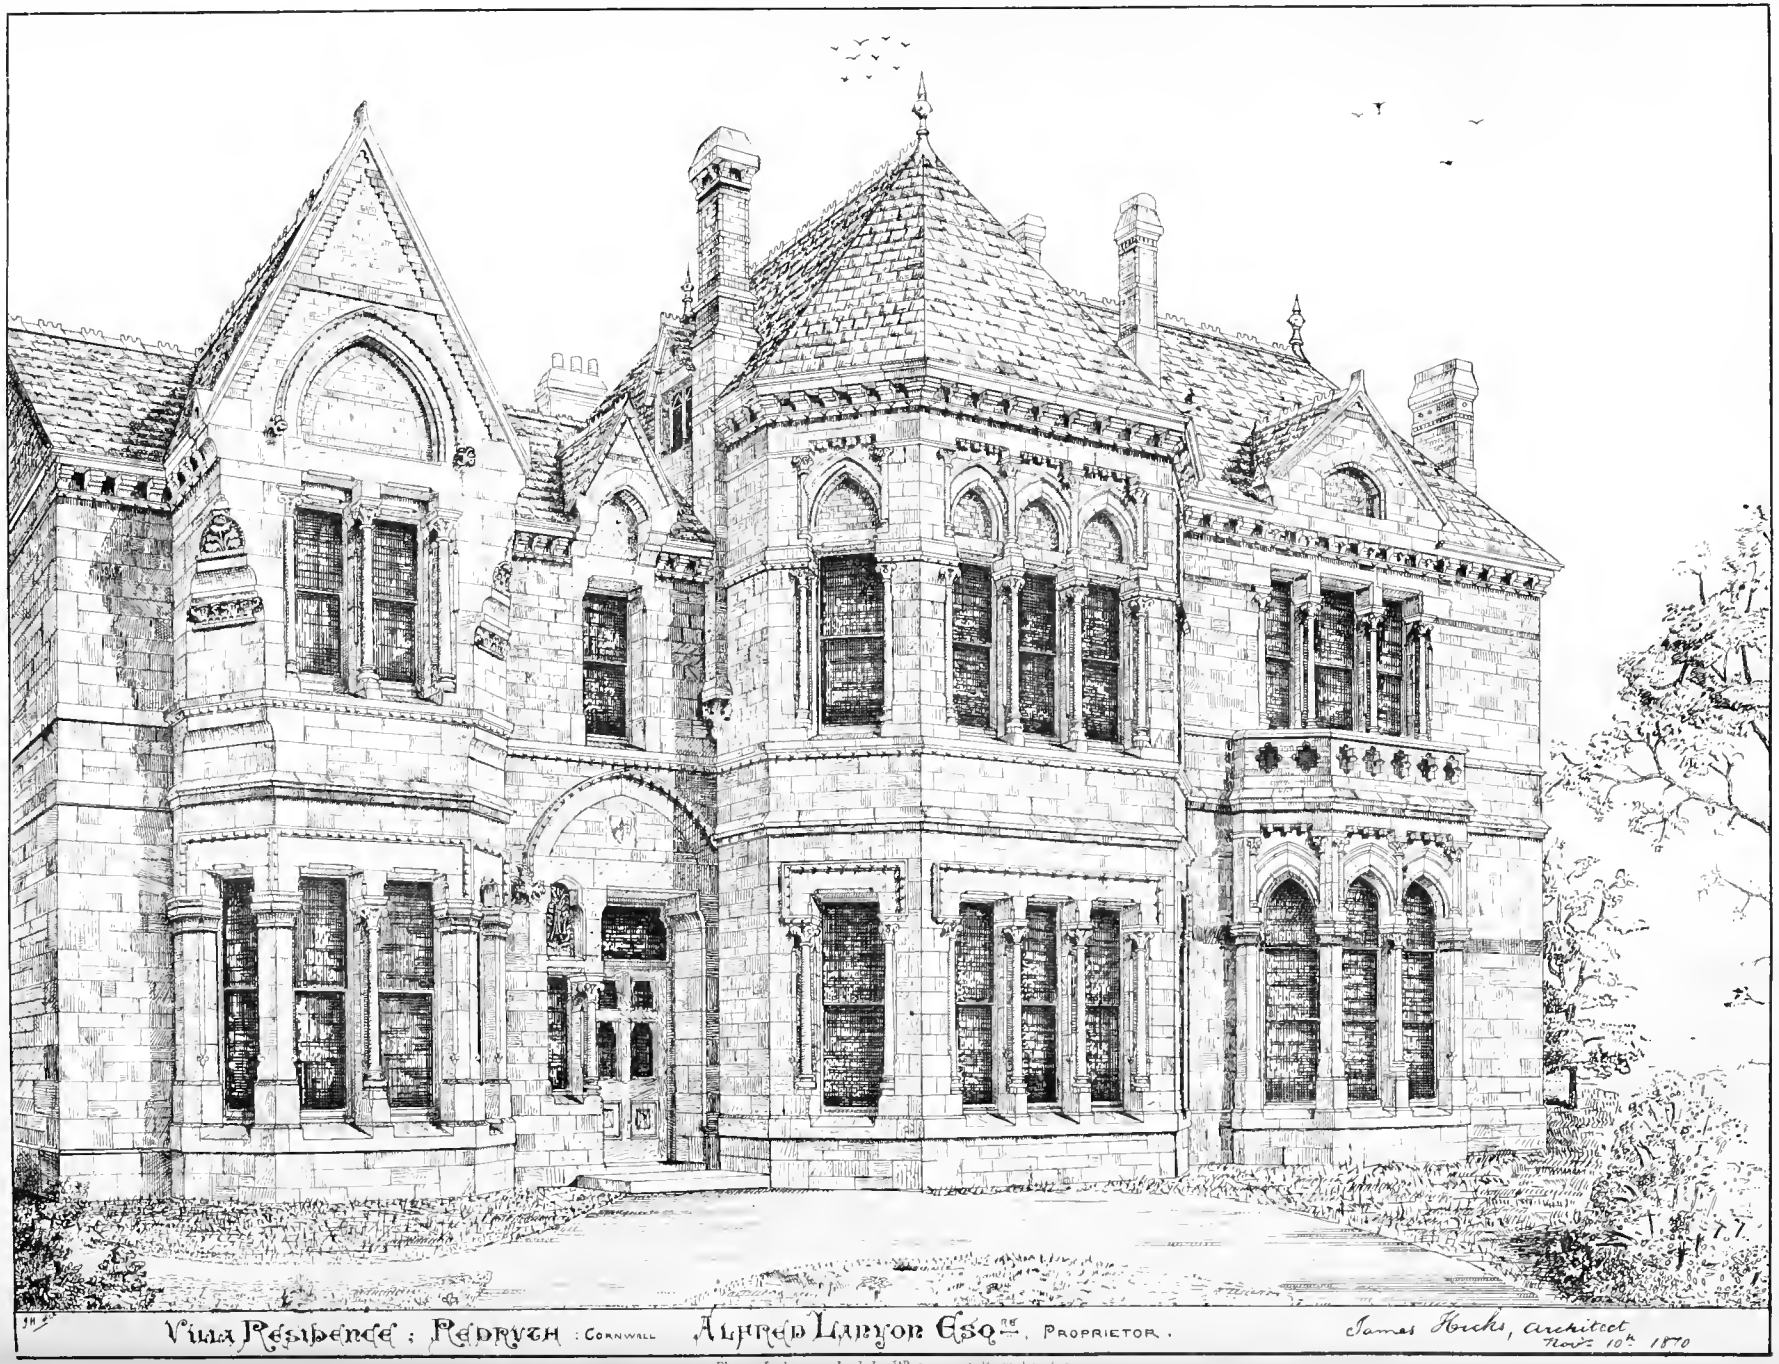
see the sanguinary contest between Greek and Greek at an end. The goddess was represented as looking down upon the amiably smiling child with motherly tenderness. The child is about to caress her chin with his right hand, whilst he holds in his left the horn of plenty. The work was full of an idealised naturalness. Next, Xenophon and Eukleides might be mentioned, who had sculptured undraped divinities. Passing, then, to Scopas, who had been born on the island of Paros, we had violent scenes of combats, which filled both sides of the temple of Athene Alea, at Tegea. The group at the back represented Achilles fighting with Telephos; that in front, the hunt of the Kalydonian boar by Herakles. Both were allegorical, and, therefore, not really artistic. No doubt allegory might, to a certain extent, be expressed in works of art, but it was not in any case desirable. The form should at once convey its meaning in striking the eye, and should not require long thought to enable the gazer to realize the object of the artist. These scenes were further calculated to inflame the passions, and art, therefore, lost its pacifying influence, and was plainly in its decline. The divinities sculptured by Scopas afforded proofs of his powerful and restless imagination, and were characteristic of the tendencies of the time. Having described the further productions of this artist, the lecturer next proceeded to those of Praxiteles, who had, he said, been born about 392 B.C. No less than fifty works, partly groups and partly single statues, he continued, were attributed to this artist, who had introduced a totally new element into sculpture. He stood to Phidias, and even to Scopas, in the same relation as Guido Reni to Michael Angelo and Raphael. Though he had created perfect models of beauty, yet this beauty was that of outer forms only; manliness, the expression of a divine thought, and the highest and purest inspiration, had been wanting. By Praxiteles all the gods and goddesses were represented as youthful. All harshness in the lines was avoided, and every idea of divine superiority in the marble form discarded. The tendency to heighten the effect of careless sensuality was to be seen even in the very position of his statues. Polykletus had made his figures rest on one foot, but Praxiteles had gone farther and made his figures lean on a support altogether separated from the body, thus materially increasing the ease of the position and creating a feeling of quiet comfort in the admirer. The various examples of the style of this artist were fully described by the lecturer, who went on to say that the refinement in art introduced by Praxiteles had been carried still further by his disciples. Amongst these, Kephisodotus the younger should be mentioned. Pliny had praised an Erotic group by him, in which the marks of the fingers had been impressed in the marble as in flesh—an objectionable naturalism. Next, we came to Lysippus, who had lived in the times of Alexander the Great. In perfect accordance with the martial spirit of the period, he had produced colossal figures of the gods. Herakles had been a favourite subject; and one erected at Tarentum was so large that the thumb was as thick as the waist of a strong man. In contrast to this large figure was a small one, scarcely 1ft. in height. It represented Herakles sitting on a rock, covered with the lion's-skin, holding a goblet in his right hand, and the club in his left. Alexander the Great always had had this with him. Portraits had been more frequently executed, Alexander being often reproduced by Lysippus. One bust was in the Louvre, and another of undoubtedly greater beauty was at Rome, in the Capitoline Museum. Art thus had taken a wider range. The genre statue had begun to interest, and the naturalistic tendency had increased. The productions of Lysippus had declined in excellence. The artist had altered the proportions of the body, especially with regard to the head, in order to give his statues a more slender appearance. No idea animated the marble, which was merely carved for the purpose of producing an effect—a sensation. Sensationalism began to rule on the one hand, and a coarse imitation of nature on th other. A description of the Laocoön (Vatican), the joint production of Agesander, Athenodorus, and Polydorus, concluded the lecture.

TOLVEAU HOUSE, REDRUTH, CORNWALL.

OUR illustration this week shows the residence, as altered, of Alfred Lanyon, Esq., Redruth, which is situated in the centre of the richest mining district of Cornwall. The old house was a very plain erection of 40 years ago, the rooms being small and only 9ft. 9in. in height. The portion to the left of the front door (shown in illustration) contains a private study, &c., and is old, except the bay-window, which is entirely new, and accounts for this portion of the building being lower than the rest. The upper part of the bay is corbelled out and treated in a bold manner, so as to prevent in a measure this portion of the house being dwarfed by the new, which is about 6ft. higher. The centre bay shows the breakfast-room; that to the extreme right the drawing-room; behind which is the dining-room, 28ft. by 17ft. Altogether there are about twenty-one rooms in the house.

The materials used have been granite for the sills, lintels, &c., and Alvan stone (similar to but much harder than Portland stone) for the facing, and a dark brown slate stone for the ordinary walling, all obtained within about two miles of the building. The carving has been very fairly executed in Bath stone by Mr. Harry Hems, of Exeter. The contractor was Mr. Thomas Jenkin, of Devonport. The retention of the old portion of the house rendered the treatment of the architecture extremely difficult, and caused more variations in the various details than would have been the case had the building been entirely new. The whole of the works were carried out last year under the superintendence of the architect, Mr. James Hicks, of Redruth.



Villa Residence : Redruth : Cornwall. Alfred Lanyon Esq^re. Proprietor.

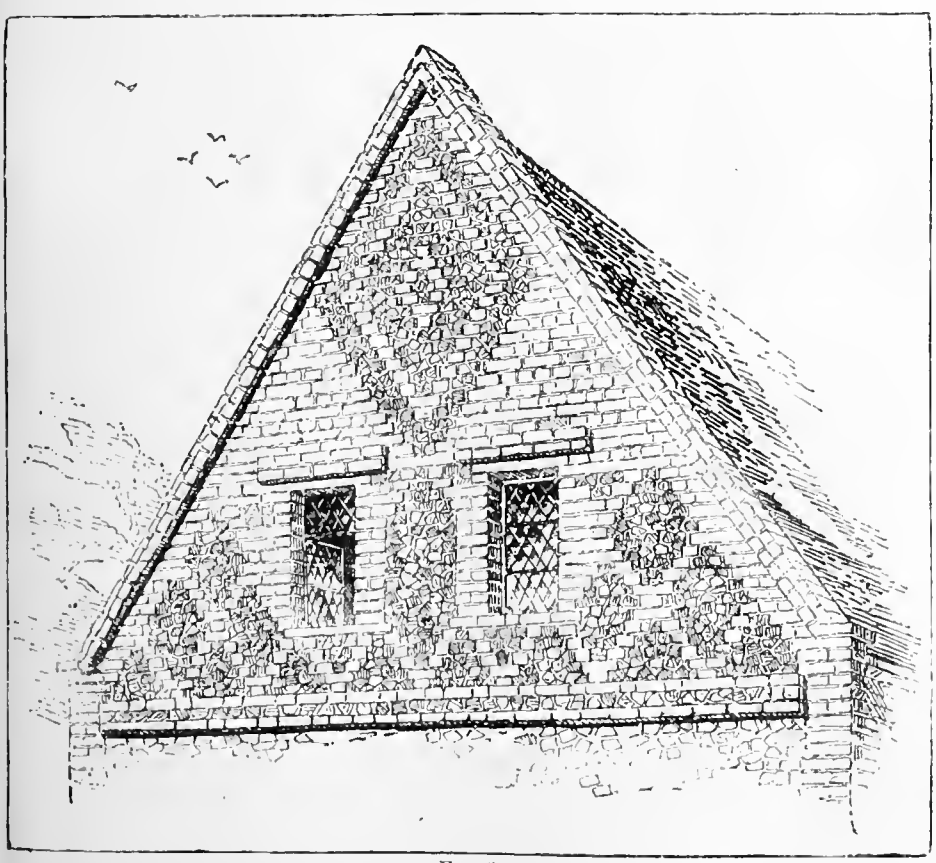

Fig. 3,

ANCIENT BRICK AND FLINT COTTAGES AT BROADSTAIRS, IN THE ISLE OF THANET.

THE accompanying illustrations of some of the old cottages at Broadstairs represent the very picturesque class of construction in brick and flintwork once apparently universal in the Isle of Thanet and many parts of Kent, and of which numerous specimens still remain, although unfortunately most have been tampered with and partially spoiled by the insertion of modern sash-windows and other incongruous features. The house shown by the engraving No. 1, is situated at the bottom of the principal street at Broadstairs, at right angles to the sea ; one that has fared better than most of its kind. Only one of the upper windows remains in its original condition, as shown in the engraving, the rest having been superseded by larger modern sash-windows. The remarkably small size of the original windows is characteristic of these cottages, and particularly of their gable ends. The lower windows now only show the outer framework with the long and short jambs of three courses of bricks in height, and the segmental arches with their key-blocks. The ancient filling-in has entirely disappeared in almost every case in the Isle of Thanet, to the great injury of their character. In the engraving, they have been restored after a pattern found so constantly in cottages on the estate of Sir E. Deering, near Ashford, as almost to be now a proof that cottages with such semicircular-headed subordinate lights must be his property. Whether or no the ancient treatment was the same I am not aware, but it seems probable, and it is, at any-rate, a good and appropriate one.

The doorway at the further end of the view (No. 1) does exist, but is perfectly hidden by growth of ivy at present. That in the middle of the façade had been superseded by a more common modern one. Over the former is a terra-cotta tablet bearing the date 1671.

The special and interesting treatment of this example is its division into panels on the first floor by means of pilasters one brick wide. These do not rest simply upon the brick band which runs as a string below them, for they are flush with this, and therefore the projection of their bases needed a provision, which has been piquantly met by making the lower course of their plinths a hollow moulding, projecting corbelwise. The pilasters have no proper capitals, but there is a frieze, the lower member of which, a single course of brick, profiles round them ; the rest, formed by blocks of two headers placed diagonally, and the spandrils filled in with cut flints, is continued between the pilasters ; and several courses of plain brickwork above form a species of cornice thrown into deep shadow by the eaves of the roof above.

The two gables are very differently treated. The one seen in the same view, without a chimney-stack rising from it, with a picturesquely carved outline and segmental pediment at top, is filled in on the face with pilasters in harmony with the front. The other gable is seen in engraving No. 2. It is not very visible from the street, but is quite worth the risk of trespass into a neighbour's yard to see ; and as the neighbour was a very civil one when I committed that offence, the risk is not a great one. The gable is as beautifully a proportioned one as I have met with, and the stack of chimneys well grouped ; the whole is executed with many little niceties of detail which will well repay a careful examination. Engraving No. 3 shows another interesting diapered gable end, which faces the same street in Broadstairs.

John P. Seddon.

The annual meeting of the Architects' Benevolen Society will be held in the rooms of the Royal Institute of British Architects, 9 Conduit-street, on Wednesday, the 8th inst., at which it is hoped by the Council that the members will make it convenient to attend.

Furniture & Decoration.

MURAL DECORATIONS IN NORFOLK CHURCHES.

THERE is scarcely a richer field to be found, and certainly not in England, for mural Mediæval decorations than the county of Norfolk; and the treasures of this character which it posseses deserve more study than they have hitherto received, the more because their continued existence cannot long be reckoned upon. Many have been only recently discovered—and, it would seem, only discovered in order, as it were, to be destroyed. Thus, with the case of a most interesting painting lately uncovered at Starston church, on the back of a recess, we are told by Mr. Phipson, in a communication on the subject to the Norfolk and Norwich Archæological Society, that the colours, when the niche was first opened, were exceedingly bright and perfect, but had become so pulverised by age that the slightest touch destroyed them; and that he found it quite impossible to secure the smallest portion, as the removal of the plaster shook the colour off like dust. Mr. Seddon gave a similar account with regard to some paintings of a bolder description, found at Llanbadarn-Fawr Church, near Aberystwith, in a short paper which he read during the last session of the Institute of Architects.

It is too generally assumed that all such decorations were but rude and coarse attempts at art, and that no great loss is sustained in consequence; but this is a grievous error. Some of the earlier ones—such as those still to be seen by the adventurous creeper into the crypt under the transept of the cathedral at Canterbury—are unquestionably most primitive in character and execution, yet even from these there is much to be learnt as to the proper general treatment of such work; and they are, besides, most valuable and interesting links in the history of art; and as no two examples of mural decoration are precisely alike, not one can be spared, if merely considered as an example of the conventional rendering of sacred subjects handed down from lone antiquity until the decay of Gothic art — all apparently obeying some general traditional laws, and yet each suggesting some new and original thought or scheme of decoration.

The painting to which we have referred above—that, namely, which was, but is not, in Starston Church, Norfolk, is illustrated by a carefully-coloured lithograph among the "Original Papers published under the direction of the Committee of the Norfolk and Norwich Archæological Society, established for the encouragement and prosecution of research into the early arts and monuments of the county." It is to be found in the seventh volume, and fourth part of the said volume, of their papers, published by Messrs. Miller & Leavens, of Norwich. It was at first supposed to represent the death of some local celebrity, but Dr. Husenbeth is quoted as an authority as to its never having been customary to represent upon church walls any family history, or anything unconnected with saints or sacred history. The explanation of the subject which is given by Mr. Phipson, and which appears to be the correct one, is, that it represents the death of the Blessed Virgin. The figure of the Virgin unfortunately has been destroyed, probably at the time of the Reformation, but the bedstead upon which she lay, and a portion of its coverings, remain, with a sort of panelled dossal at the head, by the side of which is a small painting of the Crucifixion, as if it had been a venerated object of contemplation by the deceased. Of this painting, Mr. Phipson says the execution was very beautiful, and that it was a perfect miniature, and would bear looking at with a magnifying glass; a description which evidently would not apply to the rest of the composition and its larger figures. Immediately behind the head of the bed, at the left-hand side of the picture, stands S. Paul, holding a scroll, with the inscription "*Precor te Maria.*" S. Peter, wearing a cope, is stretching his hands over the dying figure of the Virgin, and S. John appears in the background. Next appear some female mourners and various friends and acquaintances, and the remainder of the apostles complete the range of figures, which stand, as it were, behind a reddish diapered parapet or palisading; that again rests upon a sort of green cornice, with a rude scroll ornament upon it, which recals the character of ornament which we some short time ago described as connected with mural decorations which have been discovered at S. Clementi at Rome, and copies of which are now exhibited at the South Kensington Museum. In fact, the whole composition in this case has considerable resemblance to those, proving the consecutive character of the series of which all the Mediæval compositions formed a part, and enhancing the value of each separate link of the chain. The background is a yellowish green, and at the apex of the arch the soul of the deceased, as a small naked figure, is being borne up to heaven in the usual conventional winding-sheet by two angels issuing from clouds on each side. The date of the execution of this fresco is believed to have been late in the thirteenth or early in the fourteenth century.

Another curious mural painting, discovered in the church at Sporle, Norfolk, is illustrated and described in the same volume by Mr. C. J. W. Winter. It appears that in 1866 the attention of the Society was called to the discovery, by the rector of the parish, of the painting in question, and Mr. Winter made accurate drawings of the various compartments into which the composition was divided, and Dr. Husenbeth examined and explained them, and a paper of description of them, with a notice of the church, by Mr. G. A. Carthew, was published in the "Society's Transactions" of Dec. 6, 1866." The painting is executed in distemper, and the legend of S. Catherine is represented in twenty-five panels, eleven of which are drawn with great freedom and boldness of outline; but in the Virgin Saint great delicacy is pourtrayed, the colouring of her figure being feminine and subdued. The rest of the series are evidently by a far inferior hand to the first eleven, the drawing being bad and coarse, the forms grotesque and ludicrous; and the colouring, in which red predominates, is harsh. The date of the painting is indicated by the costumes, the ornaments of which, in some instances, are curious—viz., the chaplets of flowers or jewels, of rare occurrence in representations of Mediæval decorations; but the curling hair, forked beards, short-cut tunics worn close to the skin and scalloped round the bottom; the parti-coloured and motley dresses, the long toes to the boots (termed crackowes, and so named from the city of Cracow, whence the fashion was derived), the pointed basinet, &c., all belong to the early part of the reign of Richard the Second.

We must refer the reader to the paper published by the Society for the elaborate and interesting description of the several subjects of this composition, which are divided from each other by a simple red line, the whole being surrounded by a simple border, with a white and red ornament on a black ground.

SHELLAC VARNISH FOR FURNITURE, ETC.

THIS varnish has been employed by cabinet-makers upon their ware, but not generally as a finishing varnish. It has generally been employed when much diluted for the purpose of filling the pores of the wood to form a good body, previous to the application of copal or finishing polish. Shellac is prepared from a gummy substance deposited upon trees by an insect. *Seed lac* is more costly and better than shellac, being the select parts from the trees, free from many impurities which exist in the latter. Either kind forms a varnish when dissolved in alcohol, which alcohol should be a good article, say 0·80 to 0·85 sp. gr. This is the kind of varnish most frequently used by pattern makers, &c., but is hardly suitable for furniture or other similar articles on account of its containing a yellowish colouring matter which injures the appearances of the surface to which it is applied. Cabinet-makers, therefore, employ a bleached solution of shellac, particularly for white or light-coloured woods. The bleaching of shellac is generally effected on a large scale by chlorine or some of its compounds, or by sulphuric acid; the bleached article costs about 50 cents per pound, and the unbleached less than half this sum. The bleached shellac is frequently dissolved in spirits of wine for use as a varnish by cabinet-makers. This varnish is quite apt to stain any inlaid metallic ornament upon the furniture, or any metal attached to it, in consequence of the varnish retaining a small proportion of the bleaching compound in solution. Another process of bleaching may be adopted, which renders the varnish free from this objection, and very much reduces the cost of the bleached article of shellac or seed-lac. This process consists in the use of animal charcoal as a bleaching powder. It is prepared in the following manner:—Any quantity of yellow shellac, previously broken in small pieces, is conveyed into a flask, alcohol of 0·83 sp. gr. poured upon it, and the whole heated on the hob, or, in the summer, in the sun, until the shellac is dissolved; upon this, so much coarsely powdered animal charcoal is added to the solution that the whole forms a thin paste; the flask is closed, not quite air tight, and left so for some time, exposed to the sun; and in eight to fourteen days a small sample is filtered, sufficient to ascertain whether it has acquired a light yellowish-brown colour; and whether it yields a clear, pure polish on light-coloured woods. If this be the case, it is filtered through coarse blotting-paper, for which purpose it is best to employ a tin funnel with double sides, similar to those employed in filtering spiritnous solutions of soaps, opodeldoc, &c. The portion which first passes through the filter may be preserved separately, and be used as a ground or first polish. Then some more spirit is poured over the charcoal upon the filter, and the solution used as a last coating. The solution of shellac purified by animal charcoal has a brown-yellow colour, but it is perfectly clear and transparent; when diluted with alcohol, the colour is so slight that it may be used in this state for polishing perfectly white wood, such as maple, pine, &c., without the wood acquiring the least tint of yellow.

Shellac can be dissolved by an alkali, but it is rather a saponaceous compound, and it does not make a good varnish for resisting water. It is best to dissolve it in alcohol in order to get a good varnish, and one that will combine with colouring matters for various purposes. By adding some lampblack to alcoholic lac varnish, a beautiful varnish for black leather is produced.

BACKHOUSE & CO.'S NEW BANK, SUNDERLAND.

THREE weeks since we gave the interior view of this bank, and we now give an illustration of its exterior. We have nothing to add to the rather elaborate description we gave three weeks ago, p. 104, beyond stating that Mr. John Hindmarch was the clerk of works. We are indebted to Mr. G. G. Hoskins, the esteemed architect of the building, for the beautifully-executed photographs from which the illustrations have been engraved by Mr. Abbott.

THE ARCHITECTURAL MUSEUM.

THE Saturday afternoon visits of the Architectural Association to works in progress are very popular with the members. It is doubtless quite true (as Mr. Roger Smith lately remarked in a paper read before the Association) that *construction* can be best learnt on the scaffold, and hence the value of such visits in giving to the junior members—who have had few opportunities of inspecting works actually in progress—an insight into the different methods of construction suited to various requirements. But *ornament* cannot be so advantageously studied under such circumstances, even supposing all the ornament of modern erections to be worth studying, which it most decidedly is not; and therefore we think the Committee of the Association took a step in the right direction in arranging for the visit which was made by about sixty members to the Architectural Museum on Saturday afternoon last. At this valuable, but ill-supported Museum, situate in Tufton-street, Westminster, architectural ornament of all periods, and from some of the most noted architectural monuments in the world, may be studied with ease and profit, the casts being very varied as to subject, and in great profusion as regards number. Mr. J. P. Seddon, the hon. sec. to the Royal Institute of British Architects, and a warm friend of the Association, accom-

panied the visitors over the Museum, and devoted an hour to pointing out the beauties and peculiarities of the examples, and tracing the development of Gothic foliage, &c., from one period or example to succeeding ones. In this he was assisted by Mr. Wallis, the curator of the Museum. In conclusion, Mr. Seddon appealed to the members of the Association to support and attend the Museum, not only for their own but for the common good, remarking that when many of the senior members of the profession were asked to help the Museum, the frequent reply was—"Oh, what's the good? Nobody goes there." If the Museum was better attended by the junior members of the profession this excuse could no longer be pleaded.

On the motion of Mr. Lacy W. Ridge, seconded by Mr. J. S. Quilter, a unanimous vote of thanks was given to Mr. Seddon for his services on the occasion.

SCIENCE IN ARCHITECTURE.*

(*Concluded from p.* 153.)

PAINTING.

THE value of paints prepared from oxides of iron is very generally overlooked by architects. These paints some men of experience pronounce to be superior to those prepared from the oxides of lead; at any rate they answer equally well, and the cost is considerably less. But I propose to allude to the value of these paints specially for use upon iron. It has been acknowledged for years that the oxides of lead or copper, if put upon iron, will eat into it and promote corrosion, and yet how frequently do we meet with the requirement that ironwork shall have a coat of red lead before leaving the foundry: a worse provision could hardly be made, unless it be to specify verdigris, a preparation from copper; this also is sometimes used, though it eats holes into the iron in a very short time. Very shortly after ironwork is painted, the iron will be observed corroded, and the remark be upon everybody's tongue, "This ought not to be going so soon, ought not to want painting so soon." The fact is, lead has been put upon it, and nothing else could be expected. The reason red or white lead causes metal to corrode so quickly is explained thus: directly the air gets to the metal, not only does natural corrosion take place, but a chemical action sets in between the lead and the iron, and increases the corrosion. No harm can result from painting iron with red or white lead so long as the oxygen of the air or water does not get to the metal, but as it is almost sure to do so, it is best not to run the risk. The same quantity of paint made from the oxide of iron will cover a surface of twice the area as that of paint prepared from lead, though the price is much less. Aquafortis, one of the strongest acids, if poured upon red or white lead, will fuse it instantly, but has no effect upon paint prepared from the oxide of iron. With regard to the numerous anti-corrosive paints in existence, I may say, in one word, it is of no use trying to cheat Nature; anti-corrosive paints will not answer the purpose their name implies; all paints must yield eventually to the action of the oxygen, and the work be repainted, and for many reasons it is well that all work should be repainted at proper intervals. All that can be done to attain the object of such paints is to so pick and form the stuff as to reduce the power of the elements to affect it to a minimum. This is found best secured when the composition forming the paint is granular, not so finely powdered as ordinarily. The finer the powder of the mixture the greater the tendency for air holes to form as the paint is being laid on; paint that is more gritty or granular affords a better opportunity for the air to escape, and therefore reduces the liability of corrosion to the utmost limit. The coating of oil is the best preservative, and not the paint mixtures, and therefore those mixtures which, like lamp black, go a long way in mixing with oil, answer better than those that require more of the mixture to form the paint. For covering urinals or other work exposed to the influence of strong acid, black varnish is the best article to use; it should be frequently applied, and is inexpensive. Woodwork before painting ought to be well soaked with good priming, principally turpentine; this keeps damp out of the wood; a coat of paint has not the same power, as it forms a skin on the wood instead of soaking into it. The priming should pass over all the woodwork where exposed, otherwise damp may come into contact with the portion not primed, and it will find its way down the wood and cause blisters in the paint where we have thought them unlikely; blistering is often a result of insufficient priming. Painters, as a rule, neglect to prime the tops of outside doors; damp gets down the wood, and blistering results. Knots will sometimes show through paint-work, and lead to the inference that no knotting has been used, whereas the effect may be merely the result of using inferior stuff. It is of great importance that knotting of good quality be used; it may be purchased at half the cost of the well-known patent knotting, but will answer no purpose. The best driers are prepared from sugar of lead; the lighter the driers the better their quality. The quantity of driers required depends upon the time of the year the paint is used, and the character of the oil. There is a great deal of bad oil in use now, distilled or by other means prepared from resin; this will not dry properly, do what you will with it, and it should be condemned for paint work at once. It does not cost half as much as linseed oil, and there is therefore at all times danger of it getting into our work. When fresh, and sometimes when of long standing, it may be killed by an application of petroleum spirit, or potash; but generally, when this oil proves to be in the paint the best course is to scrape the whole off with salamancas or hot irons in the usual way. No oil will answer so well as linseed oil well boiled, or raw when there is not the necessity for so much driers; raw oil may be used in summer weather, and should always be used for white paints, as the boiled oil discolours them; driers in this latter case must be added. Often when we specify the best copal varnish we get nothing but common oak, though the difference in cost may be from seven shillings to twenty-one per gallon. The best proceeding for the architect is to price the varnish, and take special means for obtaining it. For ordinary purposes, where we usually specify common oak varnish, copal varnish diluted with oil answers better, and in practice is often adopted. Before petroleum came into such general use, turpentine was sold at £130 per ton, but since it has had such competition with petroleum spirit, the price has fallen to £30, or to about double the present price of petroleum spirit.

One more remark upon this subject of painting. It is a great mistake not to be particular about painting ironwork placed at the top of towers or such out-of-the way places; if not painted regularly, there is great danger of the screws and pivots that hold the ironwork together, as well as the work itself, corroding, and the whole tumbling down. I met with an occurrence of this nature recently, where the ironwork upon the summit of a spirelet fell, and on examination there was no other evident cause than corrosion; damage, of course, resulted to the buildings below.

GLAZING.

It will be a matter of regret to most of us that the use of crown glass is dying out, instead of more effort being made to improve and develope the principle upon which this quality of glass is manufactured. Sheet or cylinder glass, being made in a cylindrical form, and then flattened into sheets by bending, is necessarily defective, one surface is expanded while the other is contracted; this uneven finish consequently produces that disagreeable wavy appearance that we see in windows glazed with cylinder glass, and so long as this is used in windows the defect must exist. Clients will sometimes say the glass is not good, or it is not picked, but whatever may be desired this effect cannot be avoided with cylinder glass. Crown glass, on the other hand, is true, and has none of that wavy appearance, because on being once blown it is made, and does not require bending; the slight curve of the glass consequent on the way in which it is blown is not sufficient to present any disadvantage. The use of crown glass is dying out because it is made in such small sizes: 21in. by 18in. is one of the largest sizes cut out of a table, and therefore its use is being superseded by the cylinder glass, which is made very much larger. At present ten times the quantity of sheet glass is used as compared with the crown, and this is proved by the state of the manufacture; at the well known works in S. Helens ten sheet houses are kept going and but one crown house. Sheet glass may be freed from the waves alluded to by a process of grinding and polishing, but this makes it expensive; it is usually adopted when the glass is required for large pictures. For small size pictures crown is invariably used because of its superior transparency. In fixing glass the putty used needs careful attention; the same objection to inferior oils used in paintwork exists in reference to putty; the putty never hardens if made with these oils. A glazier told me he could now buy putty ready made for less than the cost of the ingredients with which he himself made it; of course the putty alluded to was that made from the common oils, and while it offers such advantage in price it is likely to be in great demand.

PAPERHANGING, &c.

Ordinary wall papers are now made of very common materials, and hence they may be purchased at the present low prices. Twenty years ago one and sixpence for a dozen yards was the price of the lowest class paper, now they may be purchased at 2½d. Formerly, as now, with the best papers the hanger's difficulty consisted in getting the paste soaked sufficiently into the paper to give a good key, now the difficulty is to get the paper on to the wall before it tears through saturation. The hanger used to paste several lengths and let them lie soaking, now his concern is directly he has pasted one to put it up. Formerly good linen rags only were used in the manufactore of these papers; now all sorts of refuse is used, and a great deal of jute and straw.

With regard to the durability of the prints upon papers, which, after all, is the principal thing, a good price must still be paid for papers that will last. The cheap printed papers are those that are struck off by machinery hundreds of feet at a time, and the tint cannot be made by this means to take the hold of the paper it has in the case of the hand or block made papers, by which means small portions only are printed at a time, making them necessarily expensive. Rubbing will not take off the print from these, though it soon disfigures the machine made papers. The great difficulty is to distinguish between them, since the machine made may resemble in appearance papers three times their value. Defects in paperhanging, evidenced by good papers leaving the wall, result from inattention to the quality of paste used; these require a very different strength of paste to that used for common papers.

Just one word in conclusion upon coverings for floors. Many a good floor has been seriously injured by the ill-advised use of kamptulicon; dry rot has set in the wood; this is sometimes attributed to its being put upon the floor after the floor has been washed, and the material being of that nature that it will not allow the moisture to evaporate produces dry rot; but there are other floor coverings having a similar quality, yet do not produce the same result, and the probability is that the peculiarity of kamptulicon spoiling floors is that it imbibes and retains the water poured upon it, and so presents a damp surface for a long time to the wood. It is a composition of india-rubber and cork; the india-rubber gives it its soft pliable surface, and doubtless because of its mixture with cork allows water to soak through it, but interferes, like waterproofing, with evaporation. Kamptulicon, therefore, though a nice soft material for aisles and passages, should not be used where damp may get underneath or upon its surface. Linoleum is a composition of linseed oil and cork, rolled on to strong canvass; this does not let the moisture soak through; it is not so soft as kamptulicon, but softer than ordinary floor or oilcloth. Oilcloth is formed of strong canvass stretched, and having several layers of white lead and paint coated upon it. Though not so soft as linoleum, it has an advantage in that it retains its fresh appearance much longer; any soiling will thoroughly wash off, but linoleum soon becomes disfigured, and will not clean. The longer oilcloth is kept before using the better, and if well seasoned, no other material equals it for durability and protection to floors. I need hardly apologize for this and similar digressions, since the necessity for a scientific knowledge of such details meets the architect in every turn of his professional practice.

Proposed Improvements at Dover.—The inhabitants of Dover are bent on beautifying the town, and upon copying some of the neighbouring sea-side resorts. With this end in view, a company has been formed, with a capital of £12,000, for the purpose of erecting a promenade and pier—not the most successful, hitherto, of commercial ventures.

* Read by Wm. Parsloe Esq., before the Liverpool Architectural and Archæological Society.

THEORY OF THE ARTS.

Art Education.

MATHEMATICAL INSTRUCTION.—IDEAS OF FORM AND MAGNITUDE.

(*Continued from page* 42.)

BEARING in mind that the most invariable and general laws and facts of inorganic science underlie and determine all complex phenomena or organic science, while the former are not in the slightest degree dependent on the latter, a previous knowledge of such invariable laws is absolutely necessary. Beginning with mathematics, then, as the universal basis or science of all others, the study most fitted for the primary object of exercising the faculties of perception and comparison, and giving us the simplest ideas and abstract notions, it must not be concluded, therefore, that it is the only study that can be taken up in commencing a course of professional instruction. Other sciences can be learnt simultaneously, as some of the physical ones, at least so much of them as relate to general laws; but, on investigation, it will be found that many of the laws and relations common to physics are dependent on mathematical conceptions, so that the *generality* of physical questions and ideas may be resolved into mathematical ones. Hence, I put it first as a *method*, no less than as a science of importance. Its main object being to determine one quantity or magnitude from another by the relations found to exist between them, it may be regarded as a more complex study than sciences like chemistry and general physics, where merely observed facts and phenomena form the staple of knowledge; but the incomplete state of these latter sciences, the want of the exact relations between the forces of Nature, render our present acquaintance with them of a more empirical nature, and therefore easier. In a mathematical question we have to determine the unknown from the known; we have a twofold operation to perform; we have to establish what function or relation the one is of the other. Here, then, perception and comparison are brought into play. Next, we have to ascertain the abstract value of one from the other numerically or geometrically, and thereby call into exercise the faculty of analysis and abstraction. Mathematics may consequently be divided into two parts—the *abstract*, which treats purely oft he numerical or geometrical relations of quantities; and the *concrete*, which has the discovery of the relations between distinct things or ideas dependent upon the objects investigated, as the equations of phenomena. Here again, then, we have two divisions of ideas—one the general, simple, and abstract, embracing the calculus and all numerical ideas and analysis, and the other the mixed ideas of geometry and mechanics. These latter are necessarily founded and are dependent on the pure and simple relations of number and magnitude, and therefore may be placed second. Logically, indeed, the extent of mathematical science is *universal*, and most questions can ultimately be resolved into one of number. The most isolated phenomena of physics have been, by its aid, resolved into some common relation, though it will require many years of further inquiry to establish anything like approximate numerical relations to the more complex and variable conditions of many physical and organic problems which do not readily admit of fixed members. *En passant*, the same remark may apply to many subtle questions bearing upon the æsthetics of art, such as the laws of beauty and proportion in architecture, which have already found a host of ingenious expounders, wedded, however, to various hypotheses. The failure of these theorists seems to me to be the entire neglect in most cases of other modifying elements or ideas that necessarily belong to their inquiries as applied to practical art. Starting from some abstract ration or principle, they apply it *abstractly* to a complex or organic case, without taking into consideration various contingent circumstances or specific conditions of the art which is as various as the purposes to which such art is applied. Beautiful and clever therefore, as many of the numerical, geometrical, or harmonical theories are that have been propounded by able and painstaking investigators, they one and all, I think, lose sight of the practical and organical condition of architectural design, which, I contend, must be founded upon more complex and concrete laws, as variable as the materials of the nature and purposes required of art, and therefore requiring a more encyclopœdical and comprehensive treatment ere it arrives at its "positive" phase. The method to be followed for such an end is that which takes the simple and abstract as a basis, and, by a process essentially founded upon a simple law of Nature, gradually form a chain of dependent and even decreasingly simple combination, rising from the physically-useful to the morally-perfect.

From the simply abstract *numerical relation*, to which may be referred all ratios between homogeneous things, we may pass to consider the next simple and, indeed, equally important, conceptions of magnitude or extension which geometry deals with. The province of this branch of mathematics is nearly co-extensive with that of number, though not so strictly independent of observation. All kinds of extension, lineal, superficial, and that of capacity or solidity, come within its grasp. Again, each and all of these are resolvable into the simple relations or extension of right lines, and under which all forms of nature may be measured and defined. Geometry may also be divided into two branches, as abstract or general geometry, and concrete or special geometry.

The ancients' method of geometry was *special*, and was confined to the study of certain forms of nature, in which all questions—however independent, so long as they concerned the same form—were grouped together. Modern geometry, on the other hand, treats under one view all similar phenomena or questions, separating those only that relate to the properties of special forms. It abstracts every general question as distinct from particular forms and properties, and for this more rational and progressive method we have to thank Descartes. As a fundamental course of study for the architect, no science can furnish a better method, while its application to all requirements of art makes it a study of special value. If instead of copies from the antique, landscape and figure-drawing, architectural students were grounded in the elements of form, and the various relations of lines and surfaces, simple and curved—the latter being taught rationally, as well as in a practical sense—we should ultimately see the profession taking a higher position than second-hand dealers in a defunct art, and aspiring to become devisers of one whose foundation rested not on caprice, but on science and common sense, and whose watchword, like all other species of human acquirement, was Progress.

But the manner in which most students destined for the profession pick up their practical and theoretical knowledge of this and other sciences, is grievously at fault. They begin where they ought to end. I have said there is a natural process in acquiring knowledge, beginning with the simplest facts and abstract ideas, and advancing to more elaborate ones; although a truism in statement, it is not really followed. We have a multitude of grade and rudimentary treatises, but they generally begin with some abstract definitions and ideas that had properly followed simple facts instead of preceded them. It has been remarked by an able writer, "Before knowledge can be organized some of it must be possessed," and that reasoning should begin only after an experimental introduction or observation. In opposition to this course of reasonable instruction, we have grammar before language, definitions and rules before the facts on which such mental forms are established. The conclusion of this view is, that for the purpose of instruction, objective knowledge, in other words, an experimental acquaintance with form in its endless variety should be the preliminary to geometrical knowledge as a rational science. The historical progress of the science, curiously enough, shows a similar succession; it was the special geometry of the ancients which dealt in elementary forms in the concrete that prepared the way for rational or abstract geometry.

G. H. G.

(*To be continued.*)

COMPETITIONS.

Collyhurst.—A new church, with parsonage and schools, is about to be built at Collyhurst, by Mr. Charles P. Stewart, of the Atlas works, at a cost of £12,000, exclusive of land, which he has also purchased. For these buildings six architects of Manchester and London were invited to submit designs in competition. The gentlemen who were selected to compete were Messrs. Hansom, London; Paley & Austin, Lancaster; Holden, Brakespeare, Lowe, and Dawes, of Manchester. After a close contest, the designs submitted by Mr. Lowe were selected, conditionally that they can be carried out for the stipulated sum; and to those submitted by Mr. Dawes were awarded the second premium of 50 guineas.

New Assize Courts for Birmingham.—At the meeting of the Birmingham Town Council, last week, the Estate and Building Committee reported that a large number of plans had been sent in by eminent architects for the new assize courts, judges' lodgings, and corporate buildings, which the Council propose to erect on land purchased for the purpose at a cost of some £36,000. The time for receiving designs expired on Wednesday last, and it is proposed to engage a consulting architect to advise the Committee on the adaptability of the plans. It is doubtful whether the new buildings will be proceeded with for some time. The total cost to the town will be, it is stated, £250,000.

New Bridge over the Stour at Kidderminster.—Eighteen sets of plans were sent in for the above, the estimated costs varying from £480 to £3,000 4s. 6d. Three designs have been selected by the committee, which have been sent in by Mr. George B. Ford, of Burslem; Mr. T. D. Baker, of Kidderminster; and one under the motto "Modus" for further consideration.

SCHOOLS OF ART.

Birmingham Society of Arts and School of Design.—The annual meeting of this society was held last week, Sir M. D. Wyatt in the chair. The report for the year ended the 31st December last stated that the classes had been well filled during the past year, the numbers attending having been 1,077. In 1869 they were 1,115. One prize and three honourable mentions were awarded amongst seven competitors. The school received one bronze medal at the National Competition at South Kensington in May last. This very unsatisfactory amount of success at the great National Competition of all the schools had been under the serious consideration of the committee. An investigation into the cause was being carried on, and the committee had recently had an interview with Mr. Bowler, official inspector of the South Kensington Art Department, with reference to the subject. The annual Government examinations in drawing, perspective, and geometry were held in March last. 315 students entered for examination, of whom 219 were successful, and forty received prizes. Forty-eight third-grade prizes of books were awarded for works sent up for inspection in London; the number last year was twenty-nine. Special prizes had again been liberally offered for original designs for manufactures, the results of which would be made known at the annual meeting. Five prizes had also been awarded for home studies, the competition being limited to artisans. The committee were glad to find that the students continued to avail themselves of those means of self-improvement commenced last year. Two students, W. H. Marklew and Thomas Reeves, had obtained National Scholarships at South Kensington of £52 per annum, making eight from this school who had had this opportunity of studying in London, of whom three remained under instruction. A class for

wood engraving had been commenced as an experiment. Five pupils entered, one of whom was obliged to abandon the study on account of her sight. The others had made satisfactory progress, and the class had entered upon a new session with an increased number of students. The income of the school was again satisfactory, there being a surplus of £27 4s. 9d. to carry forward; still a balance of an old debt, amounting to £173 12s. 8d., remained at Christmas last, which ought to be extinguished.

ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETIES.

EDINBURGH ARCHITECTURAL ASSOCIATION.—The fortnightly meeting of this Association was held on Wednesday week, Mr. R. Morham, jun., president, in the chair. A paper was read by Mr. William Richardson, entitled "A few remarks on the Architects and Architecture of the present day." Mr. Richardson drew attention to two matters which, it appeared to him, greatly required amendment. One of these was the relations between architects and those in their employment. He deprecated the common custom with some architects of having their work done by pupils instead of by regularly-trained draughtsmen; and proposed that something should be devised by the latter in the form of a union, such as obtains among certain trades, to restrict the number of pupils. The other topic on which Mr. Richardson principally dwelt was the want of a due appreciation of architecture at the present day; and he showed that until a more general interest was taken by the public in the art, little was to be expected in the way of amelioration. Remarks having been made by several members, a vote of thanks was awarded to Mr. Richardson for his address.

OXFORD ARCHITECTURAL AND HISTORICAL SOCIETY.—The first meeting this term was held in the Ashmolean Museum on Wednesday evening, the 15th ult., when an interesting paper on the history of Merton College was read by Mr. E. G. Bruton. The College itself was visited on Saturday week, when nearly a hundred of the members and their friends were present. They were received in the Hall by the Bursar, Rev. S. Edwardes. After a short address from him, Mr. Bruton exhibited a chronologically-coloured plan of the College, and pointed out the order in which the several buildings were erected, the approximate date of which he stated. Mr. James Parker made some remarks on the stained glass in the Chapel. The party then visited the City wall, when some interesting particulars were given by Mr. Parker, who said that the probable date of its construction was about the middle of the reign of Henry III.

PARLIAMENTARY NOTES.

HYDE-PARK AND THE ALBERT MEMORIAL.—Mr. H. Lewis, on Monday week, asked the First Commissioner of Works whether it is in contemplation to take any and what portion of Hyde-park on the south front of the Albert Memorial for improving the Kensington-road at that part; and for what purpose the work in Hyde-park on the south front of the Albert Memorial is now being carried on.—Mr. Ayrton said the work to which the hon. gentleman referred was the construction of some steps connected with the base of the Albert Memorial, which were required to carry out the original design. With regard to the road, an arrangement was come to last year with the District Board of Works of Westminster to prosecute a Bill to improve it, but that Bill was not proceeded with, and therefore the arrangement fell to the ground; and as the Exchequer did not undertake to pay the expense of improving the metropolitan roads, unless the District Board could make an arrangement with the Metropolitan Board and the Exhibition Commissioners to carry out that desirable improvement, as he trusted they would be enabled to do, he did not see how that object was to be effected.

THE HOUSES OF PARLIAMENT.—Col. Wilson-Patten gave notice, on Friday last, of his intention to call the attention of the First Commissioner of Works to the rapid decay last winter of the stone of which the Houses of Parliament are constructed, and to ask if he was prepared to take any measures in consequence.

THE HOUSES OF PARLIAMENT.—Col. W. Patten on Tuesday asked the First Commissioner of Works whether his attention had been called to the rapid decay which had taken place during the winter of the stone of which the Houses of Parliament are constructed; and whether it was proposed to take any measure with respect to it.—Mr. Torrens also inquired whether the external portions of the Palace, reported on by Professors Faraday and Murchison in 1860 as having been up to that time preserved from decay by the indurating composition invented by M. Szerelmy, continue to resist the tendency to exfoliation of the surface of the stone observable in other parts of the building.—Mr. Ayrton said it could not be doubted that unfortunately a certain quantity of defective stone was used in the construction of the Houses of Parliament. Moreover, in large works of this kind, were some of the stones were highly carved, some pieces probably got broken, and here and there the broken pieces were put in in a very defective and improper manner, and as time wore on these defects became apparent, the bits of stone fell off, and created considerable alarm in respect to the stability of the building. That alarm was, however, entirely unfounded, and there was nothing at all which really affected the general character of the stability of the stone work of which the Houses were constructed. Some years ago the subject was carefully considered, and experiments were made with various processes to endeavour to preserve those stones which had exhibited signs of decay; but he was sorry to say that a sufficiently accurate record was not kept of these steps to enable them to judge satisfactorily of the effects produced. Not one, however, of those efforts had proved altogether successful. Of the many attempts, that of M. Szerelmy was undoubtedly proved to be the best; but still it was not one which could be relied upon for the permanent preservation of the defective stone. What had been done last year was to make an application of all the processes, under the superintendence of a competent chemist, and in the course of the spring it was intended to treat all the defective stone with that process which the chemist might, on the whole, think would be most efficacious. If it were found that some of the stones were greatly eaten into, it would be necessary that they should be cut out and new stones introduced; and in that manner, by constant attention to their repair, and at a comparatively small expense in each year, there was no doubt the outside of the building could be preserved for many centuries to come.—Colonel W. Patten inquired whether the attention of the right hon. gentleman had been called to the fact that it was the solid masonry which was giving way?—Mr. Ayrton said he was quite aware that some of the stones had been considerably eaten into by decay, and the face of these stones would have to be cut out and new faces introduced.

Building Intelligence.

CHURCHES AND CHAPELS.

BEESTON-HILL.—Sir Andrew Fairbairn, on Tuesday, laid the foundation-stone of a new church at Beeston-hill, Leeds, to be called S. Luke's. Messrs. Adams & Kelly, of Park-row, Leeds, are the architects, and Messrs. Weatherby & Rymer, of York, the contractors. The style adopted is fourteenth century Gothic. There will be a clerestoried nave, with north and south aisles; and chancel, with organ chamber and vestry on the south side, and aisle on the north. The entrances are on the north side, and a separate entrance to the vestry is provided. Internally, the dimensions are:—Nave, 80ft. 6in. long, 47ft. 6in. wide; height from nave-floor to ridge, 52ft. 6in.; chancel, 30ft. long, 20ft. 6in. wide. Accommodation is given for 695 persons, and the estimated cost is £3,121. The building of a tower is in prospect when the funds will warrant that step being taken.

LINCOLN.—A new (Roman) Catholic church is to be built at Lincoln. Messrs Hadfield & Son of Sheffield, the architects, have furnished the design for the structure. The style is Later English decorated, only that the church is apsended.

LUDLOW.—A new church, which will also serve as a cemetery chapel, was opened at Ludlow on Tuesday week. It is in the Early English style of architecture, simply treated, and consists of a nave, chancel, and vestry. It is built of stone from the neighbourhood of Felton, the Clive estate, and dressed with stone from the Luston quarries. Accommodation is afforded for upwards of 200 worshippers, and the total cost is about £1,800. The architect is Professor G. G. Scott, the contractor being Mr. E. Edwards, Leominster.

BUILDINGS.

CHATHAM.—The Government has decided on the erection of a large central powder magazine on the uninhabited marsh land between Chatham and Sheerness, adjoining the Medway, at an estimated outlay of £90,000, which sum has been taken in this year's estimates. Of this amount, £20,000 will be voted this year, and the remainder as the work proceeds. The sum of £21,000 has likewise been taken in this year's estimates for the erection of a Royal Engineer Institute and halls of study, at the School of Military Engineering, Brompton.

BLACKBURN.—On Saturday last, a new school, the gift of Thomas Dugdale, Esq., J.P., of Griffin Lodge, Wilton, was opened, and dedicated to the use of the township for ever. The school is built in the centre of the Griffin estate, entirely of stone, and cruciform in model, with a small chancel, approached by a Gothic arch, for the purpose of public worship. It will accommodate 400 people, and is from the designs of Mr. James Bertwistle, architect,, Blackburn.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

THE *BUILDING NEWS* SKETCH BOOK.

In addition to those acknowledged last week the following contributors have recorded their votes:—W. H. Lockwood, Geo. Holford, W. D. Dobson, J. R. Allen, W. Bingley, W. W. Bethell, Geo. Remington. Wednesday, the 15th inst. is the latest period for the receipt of votes.

RECEIVED.—W. H. C., R. D. & Co., T. H. S., W. Backhouse, J. H., W. S., A. S., J. C. J., W. H., A. & G, J. H. W., W. W.

J. HICKS.—Drawing returned.

J. P. S.—Illustration of national schools shall appear.

H. J. SNELL.—*Two* sketches returned.

F. TITTERINGTON.—You are at liberty to reply to anything you deem incorrect. We give neither names nor addresses.

Correspondence.

NEW LAW COURTS.

(*To the Editor of the* BUILDING NEWS.)

SIR,—"'F.'s' attempt at a simple solution" neither warrants "J. M. L.'s" strictures, deserves his ungrammatical misquotation, nor requires his unintentional corroboration.

The "open confession" à la novitiate (*not* "noviciate") is entirely an act of supererogation; so also is the solicitude to avoid initiation into the unfathomable! Leaving "J. M. L." still to contend that errors in bills of quantities are best reduced to a minimum by monopoly in preference to the application of that crucial test, competition, and the indubitable check a second surveyor would exercise on his confrère, to the quotation of such, to him, delectable embellishments as "wireing in to keep their names up," and to the enjoyment of the comatose state consequent on the *naively* admitted cessation of wonder—I am, &c., with apology for indiscretion, F.

THE ROYAL ALBERT HALL, KENSINGTON GORE.

SIR,—I am at a loss to understand the purport of the letter you published last week on this subject from an anonymous correspondent, who shields himself behind the initials of an honourable and kindred profession. Perhaps, however, the only mistake "C. E." has *not* fallen into in favouring your readers with his views has been in withholding from them a name which would give no value to his remarks. I have not seen the article in the *Echo* which has provoked his ill-natured strictures; and I should not have taken any notice of his letter but for the many gross mis-statements which it contains.

"C. E.," in order to prove his scholarship, I presume, drags in the mention of the Emperor Vespasian, who did not build the Coliseum, as it was for the most part, if not entirely, constructed by his son, Titus, and dedicated by the latter, according to Maffei, "in his own, and not in his father's name." The statement that the Albert Hall is a direct copy of the Coliseum shows how

little "C. E." knows of what he is talking about, for either he has never been in the former, or he has never seen an ideal restoration of the latter.

The fact is, that the hall was originally rectangular in plan, then circular, and, lastly, was made elliptical, purely with the intention of accommodating the largest number of spectators, or, rather, hearers, with equal facilities for enjoying the performance.

The ancient amphitheatres had no roofs; the great problem in the Albert Hall was to cover so large an area. The boxes, balcony, and promenade or gallery of the hall, are entirely above the solo singer, and accommodate three-fourths of the audience. More than half of the remaining number are seated in the so-called amphitheatre on a level with the performers, while the flat central floor of the hall is only to seat 900 persons at a level of 6ft. below the solo singer. By preserving a large floor-space—102ft. by 65ft.—in the centre of the building it becomes possible to hold flower-shows and exhibitions, or chamber music and public meetings readily visible or audible to a large number of visitors. The second paragraph of the letter deals with a matter of individual opinion, and as such, coming from the mere initials "C. E.," is valueless. The argument that because we have some ruins of an open building at Rome, erected for wild beast-shows, therefore the erection of a building of a somewhat similar shape for musical purposes in London cannot be called an experiment, is absurd. The promenade or picture-gallery above the staircases and waiting-rooms is, to a certain extent, a structural necessity; and the way in which Colonel Scott has overcome a difficulty by the introduction of an open peristyle (a feature entirely absent in ancient amphitheatres) is, I maintain, one of the most successful points in the design of the building.

I cannot follow "C. E." in his proposals about the organ-chamber, apart from the hall but having free acoustic communication with it; perhaps he is not aware that such conditions could only exist on paper. "C. E." must study the elementary laws of acoustics before he dictates such sweeping measures as the broadside principle; he would then learn that sound travels more readily forwards than sideways, and that he could make himself heard by an infinitely larger audience extending the long way of a given ellipse than he could by addressing them from the short axis of the building. But the most unfortunate mistake of all made by "C. E." is in talking of the approaches to the hall. Probably no modern building, with the exception of the New Opera House at Paris, is so amply provided with accommodation in this respect. Instead of the four entrance-doors he speaks of, we have 22, and the same number of staircases, with 9ft. corridors all round the building at every level. Why, the Coliseum, with its 80 barn (?) doors for 85,000, or, as some say, 100,000 people, was nothing to the Albert Hall with 22 doors for an audience of 10,000. In a notice in the *Times* of Monday last of a concert at the hall on the previous Saturday, special attention was drawn to the fact that an audience of between 8,000 and 9,000 was dispersed in a few minutes. Coming to the final paragraph, I am fairly puzzled what connection it has with the rest of the letter; or what the Society of Arts' *conversazione* has to do with the space in the hall, I cannot for the life of me make out. I can only presume that it has been added with the intention of showing that on some treasured occasion "C. E." has had the rare and undeserved honour of being present at a South Kensington soirée, and cannot get the remembrance of the august condescension of the "high authorities" out of his head.—I am, &c.,

Gilbert R. Redgrave.

SOCIETY OF ARTS—ART WORKMANSHIP, 1870—71

Sir,—In reference to the letter from Mr. Bassett Keeling, published in your last impression, permit me to say that the entry in the Society of Arts catalogue reads as follows:—"No. 13. Inlay in various woods. 'Our Saviour,' designed by Bassett Keeling, executed by William Clayton, 125, Wardour-street, St. James's, S. W." I think therefore that no blame can be attached to—Yours, &c. The Writer of the Article.

SATURDAY HALF-HOLIDAY.

Sir,—Your correspondent "A. Y. Z." has placed before the profession some very interesting statistics on this matter. That such a state of things can exist in a profession of intelligent men can only be accounted for by the supposition that those who deny their assistants the half-holiday are either old fogies, long past redemption, or a few nobodies from whom we can expect nothing better. Still it is a great pity, I might say a scandal, that the young men in their offices are denied a privilege so universally granted to those in their position. The no-half-holiday men must be very blind, to their own interests even, to continue such a condition of things; and if they think that having done without it themselves therefore their assistants may, it would be interesting to know how much better they would have done with it. And this they might easily know, to some extent, at least, by looking round among their old fellow-pupils, whom they will see do succeed even with a little more leisure.—I am, &c.,

Forward.

Intercommunication.

QUESTIONS.

[2134] REMOVAL OF ROSE TREES.—Will some of your correspondents kindly inform me whether rose trees are legally removable from a garden?—A. S. A.

[2135] WOOD-WORKING.—Can any of your readers kindly inform me of the address of a wood-working firm in Vienna; and if they have an agent in London?—Quercus.

[2136] SOLE CONTRACTS.—I intend to build a villa in Scotland; my architect advises the different parts of the works to be let to separate contractors, assigning as a reason that separate contracts are the most economical, and that he finds the system of sole contracts is not now so generally adopted in England as it was formerly. Can any kind reader who may have experience in these matters, inform me which is the safest way, and whether does the system of separate contracts confer the greatest benefit on the proprietor, architect, or contractor?—A Subscriber.

[2137] FOUNTAINS.—I should feel obliged if any of your subscribers would inform me if there is any book published on the subject of fountains; or if they could give me an idea of the apparatus required to throw a jet of water about 20ft. high?—J. F. S.

[2138] PLUMBERS' WORK.—May I ask an explanation of the following, at p. 152, third column?—"The regulating cisterns of some houses I recently examined leaked in most instances, though they were comparatively new. I found the cause was the valve being flush instead of raised" &c. Although a plumber myself, I must confess my inability to understand properly what is meant from the way it is stated.—P.

[2139] SURVEYORS CHARGES.—Can you or any of your kind readers inform me what surveyors usually charge for surveying and making out schedule of dilapidations or tenantable repairs, without estimate of cost; and also what they charge with estimate of cost?—L. B.

[2140] MARKS ON TIMBER.—I shall be glad if any of your correspondents will reply to the following:—1st, Is there any book published giving all the marks (and their meanings) on different kinds of foreign timber and floor-boards? For instance, what does A H K + C on the ends of white floor-battens signify? 2nd, is there any work describing the various qualities and kinds of timber, and how they may be known?—Architectus.

REPLIES.

[2126] PLUMBERS' WORK.—The remarks of "Wiltshire," at p. 154, apply to soldered tacks; that is, to tacks or nails covered with solder; but the query referred to "lead-soldered tacks," consequently, we are as far at sea as ever if the expression "lead-soldered tacks" be correct.—P.

[2126] PLUMBERS' WORK.—Are "soldered dots" synonymous with "lead-soldered tacks" and "lead-headed nails" mooted last week?—F.

[2127] ANCIENT CHURCH ARCHITECTURE.—The best book, considering the great amount of information, number of illustrations, and lowness of price, for a beginner, is the last edition of Rickman's "Gothic Architecture," published by Parker.—P. E. M.

[2128] ISOMETRICAL DRAWING.—"A Treatise on Isometrical Drawing," by T. Sopwith, F.G.S., second edition. Easy and accurate in its application.—M. G.

[2128] ISOMETRICAL DRAWING.—"Cupidus Discendi" will, I think, find W. S. Binns's treatise on "Orthographic and Isometrical Projection" (in two parts), answer all his requirements.—C. W. H.

[2132] CUBING BUILDINGS.—The dimensions for cubing must be from outside to outside laterally, and from bottom of footings to half way up the roof. No deductions are made for floors or aught else inside. The enquirer must bear in mind that cubing can only be relied upon when the relative circumstances are exactly similar.—P. E. M.

[2132]—CUBING BUILDINGS.—"Wiltshire" should take the dimensions externally, and from ground to eaves, cubing the same as a solid block; then cube the roofs, &c., separately, and add their contents. Cellars to ordinary houses, outbuildings, and offices to mansions should be cubed and priced at a lower rate. Porches, bay windows, balconies, and ornamental chimnies; estimate these and add their value to form an approximate only.—W. R. A., Uckfield.

[2132] CUBING BUILDINGS.—Measure externally in all cases, and for heights take from bottom of footings to centre of roof.—F.

[2133] COMPETITIONS.—In the absence of any special circumstances, such rejection would most assuredly be unjustifiable, and more, an adhesion to their decision, *nolens volens*, should be effected. If called on to prescribe, would probably do so thus: Law, strong dose, promptly and vigorously applied; repeat doses until cured.—F.

[2133] COMPETITIONS.—The committee cannot be compelled to employ the assistant, but it is to be hoped they will take a liberal and kind view of the case. It is not of any importance to them the position of the successful competitor, but only whether he is competent to execute the work. If he can show proof of this, they are certainly in honour bound to employ him.—P. E. M.

[2133] COMPETITIONS.—In answer to "T. C.," as a friend, I beg to say, whilst experiencing as he must the most unalloyed gratification at the preference given to his design—the result of many a well-spent hour of "overtime"—although disconcerting if it be not deemed such an one from which the hall can be advantageously built, or if for divers reasons not assigned (for the committee is not bound to state why or wherefore) it be rejected, let him be assured that the fault of his production being only that of an architect's assistant would not influence a committee of gentlemen to refuse the design on that account. Therefore, if an unfavourable decision should be made, let him not be advised by any one to try to enforce its adoption. Let him wait patiently, not be daunted, and hope on! The selection of "T. C.'s" design is a proof of its superiority, and augurs well for the future; and if it does not meet the reward due to its worth now, it cannot fail to help him up another step on the ladder of fame.—W. R. L.

LAND AND BUILDING SOCIETIES.

Commercial Union Permanent Benefit Building Society.—The first annual meeting of the Commercial Union Permanent Benefit Building Society was held last week. The gross receipts were stated at £12,134, the advances at £8,831, and the realized profit at £1,091, showing, after payment of 5 per cent., a profit carried forward equal to 12 per cent. on the paid-up capital for division next year.

Essex Equitable Permanent Benefit Building and Investment Society.—This society lately held its twenty-third annual meeting at Orsett. The report showed that during the past year 106½ new shares had been entered; that the total receipts amounted to £3,346 15s. 11d.; that £2,831 had been paid to parties withdrawing investments; and that advances to the amount of £438 4s. had been made. The statement of liabilities and assets showed the sum of £7,108 3s. 6d. as the total amount due to investors being holders of paid-up and monthly subscribing shares; whilst the amount due from borrowers is £7,628 6s. 3d., leaving a balance of £520 2s. 9d. in favour of the society.

Waltham Abbey Permanent Benefit Building and Investment Society.—The twenty-third annual meeting of this society was held the other day. From the report presented to the meeting it appears that the society now consists of 353 members, holding collectively 1,137 shares, being an increase of 114½ shares on the number mentioned in the previous report. During the past year 255¾ new shares have been taken up; 129¼ have been withdrawn; ten redeemed; 70 advanced; and 2 have been forfeited. The receipts during the year (including loans of £2,400 obtained by the trustees to enable the directors to meet the applications for advances), amount to £12,359 1s. 11d, which, added to the balance of £7 5s. 5d., makes a total of £12,366 7s. 4d.; of this sum £4,209 14s. 1d. has been advanced to aid in the purchase of property; £4,967 2s. 2d. has been paid on the withdrawal of shares; £42 8s. 1d. interest of loans; £2,700 in part payment of loans; and £108 4s. 5d. for other charges, leaving a balance in hand of £331 7s. 10d. The report was unanimously adopted.

LEGAL INTELLIGENCE.

Infringement of the Metropolitan Building Act.—At the Southwark Police Court, last week, Mr. Joseph Torr, builder, Lawson-street, Dover-road, was summoned for unlawfully erecting a warehouse in S. James-street, Old Kent-road, without giving the required notice to the district surveyor. Mr. Snooke, architect and surveyor, of Tooley-street, stated that he was the district surveyor of the locality where defendant had built extensive warehouses in S. James-street, Old Kent-road. According to the clauses of the Building Act, he should have given witness notice, accompanied with plans; but neglected to do so, and proceeded with the building. The latter was not erected according to law; the walls were not of sufficient thickness for the weight of the roof. Mr. Smith, on the part of Mr. Torr, said he had to apologise to Mr. Snooke for his neglect in not giving him notice. The fact was, he applied to the Metropolitan Board, to whom he sent in his plans, and they gave him a licence (produced). He had consulted with Mr. Byron (who appeared for Mr. Snooke), and he (Mr. Byron) did not wish to carry the case any further against his (Mr. Smith's) client. Mr. Byron said that after such an apology and explanation he was willing to forego any further prosecution in the matter, but as Mr. Torr wilfully infringed the Act of Parliament he must ask for a conviction. Mr. Partridge, the magistrate, after some further remarks, considered that a nominal penalty would be sufficient. Mr. Torr must pay a fine of 5s. and costs.

Christ Church, Montpelier.—The embellishment of the apse of this church has just been completed by the filling in of the nine lancet lights with coloured glass windows. The pictorial designs of these windows are all taken from New Testament history. The centre light displays the Crucifixion. Messrs. Clayton & Bell, of London, were the manufacturers.

The Sanitary Act in St. Luke's.—The Vestry of S. Luke had enforced this Act in 1866, and as a consequence the fever cases in that parish had diminished as follows, viz. before the Act had been passed there were 766 cases in one year; since the Act, there had been but 207 cases in 1867; 179 in 1868; 174 in 1969; and only 100 in 1870

Our Office Table.

PROPOSED MORTUARY, &c., FOR NEWINGTON.—The Vestry of S. Mary, Newington, has purchased of the London, Chatham, and Dover Railway Company seventeen railway arches, and a piece of land adjoining, for 1,000 years, for the sum of £4,300. The ground and arches are to be utilised for manifold purposes, including the erection of a mortuary, the storage of dust and slop, the establishment of a stone-yard, and, if necessary, for the erection of a temporary small-pox hospital. The arches purchased are those which carry the railway between Manor-place and Penrose-street, Walworth, and the piece of land adjoining is an old disused burying-ground formerly belonging to the old Episcopal Chapel in West-street (now Penrose-street.) The chapel is now carried on by the Unitarian body. The railway company has agreed to make a siding on to the property of the Vestry, so that the dust and slop may be conveyed by rail to brickfields and market gardens down the line.

THE PEABODY DWELLINGS FOR THE POOR.—According to the annual statement of the Trustees of the Peabody Donation Fund, the first trust now amounts to £178,733. Five groups of buildings under it, situated at Spitalfields, Islington, Shadwell, Westminster, and Chelsea, afford collectively accommodation for 498 families. The trustees possess a site at Bermondsey, which has not yet been built upon. The second donation of Mr. Peabody, to the amount of £200,000, became available for building purposes in July, 1869, and its accrued interest amounts to £13,918 1s. 7d. To this gift Mr. Peabody added, by his last will and testament, £150,000, but in accordance with the terms of the bequest this latter sum will not be conveyed to the trustees until the year 1873. Under this trust there are now in course of construction sixteen detached blocks of buildings on the premises purchased last year at the southern end of Blackfriars-road, and formerly known as the Magdalen Hospital estate. This property will afford dwellings for upwards of 300 families. The trustees have also a desirable site at Chelsea, situated on Cheyne-walk, near the Cadogan pier, available for future requirements.

TRAMWAYS AT NEWINGTON.—We have on previous occasions referred to the proposed removal of the parish church of S. Mary, Newington, the eastern end of which juts out very awkwardly into Newington Butts, causing an awkward bend and contraction in the road. The Metropolitan Street Tramways Company, having now obtained powers for the construction of a line of tramway from the Elephant and Castle to the junction of the Westminster, Brixton, and Clapham tramways at the Horns', Kennington, the Tramways Company has, with an eye to business, offered to contribute £1,000 towards the removal and rebuilding of the church, upon condition that the Newington Vestry will relieve the Company of certain conditions they are under as regards paving. At the last meeting of the Vestry the offer of the Company was agreed to, and there is reason to believe that a much called-for improvement will be facilitated. We understand that the site of the new church will be on the east side of the Kennington Park-road, nearly opposite Mansion House-street.

SHUTE'S PATENT MITREING MACHINE.—A new mitreing machine has just been patented by Mr. R. G. Shute, for which several advantages are claimed. It will cut a clean and perfect-fitting mitre. Mouldings of any kind of wood up to 4½in. wide can be made by it, and from the peculiar direction in which the knife cuts, it will mitre Bolection or return mouldings of any pattern without splintering them. Messrs. A. Ransome and Co., of Chelsea, are the sole manufacturers.

IRON AS A DEODORIZER.—Dr. Voelcker calls attention to the use of spongy iron as a deodorizing material of greater potency than animal charcoal. Sewage water passed through a filter of this substance is completely purified, and this filtered water, after having been kept six months protected from the air, was perfectly sweet, and free from any fungus growth. The spongy iron is obtained by calcining a finely divided iron ore with charcoal. Mr. Spencer, whose name is connected with the discovery of the electrotype, has for some time been advocating the use of a filter of this description. Its power of rendering water beautifully transparent, and apparently free from all organic matter, is its strong recommendation.

A LARGE RAILWAY BRIDGE IN INDIA.—On New-Year's Day Lord Mayo opened the Gealunde Extension of the Eastern Bengal Railway, which supplies the great missing link in the chain of railway communication between Calcutta and Eastern Bengal. The extension has been for some five years in course of construction, having to cross the Goraie river, the deep and treacherous stream which carries off to the sea the main body of the waters of the Ganges, an obstacle requiring no small labour to overcome. The Goraie Bridge roadway is laid across transverse girders resting on seven pairs of cylinders having to bear the pressure of a volume of water some 90ft. deep, and which have consequently been sunk in the bed of the river for a distance equal to about two-thirds of their height above it. There are eight spans, each about 180ft. long, and seven longitudinal girders on each side, each weighing 160 tons. The extreme length of the bridge is 1,600ft.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—*Royal Institute of British Architects.*—Annual General Meeting of Members only. 8 p.m.
Society of Engineers.—"On the Machinery and Utensils of a Brewery." By Mr. Thomas Wilkins. 7.30 p.m.

TUESDAY.—*Institution of Civil Engineers.*—"On Phonic Coast Fog Signals." By Mr. Alexander Beazeley, M. Inst. C.E. 8 p.m.

WEDNESDAY.—*Society of Arts.*—8 p.m.

THURSDAY.—*Society for the Encouragement of the Fine Arts.*—Second *Conversazione* of the Season, at the Gallery of the Society of Female Artists, 9, Conduit-street, W. 8.30 p.m.

FRIDAY.—*Architectural Association.*—"On Christian Symbolism." By Mr. G. H. Birch. 7.30 p.m.

Chips.

In order to purchase and work certain improvements in the manufacture of washable wall papers, the Amaranth Paper Staining Company has been formed, with a capital of £30,000 in £1 shares.

A new iron Presbyterian church was opened on Sunday, at Annbank, N.B. The style is Gothic. The building seats 250 persons at a cost of £350.

A new Congregational chapel will be opened on Sunday next at Rock Ferry, near Liverpool. The designs are by Mr. D. Walker.

The laying of a double line of street tramway from the Elephant and Castle to Camberwell-Green will be commenced early in this month.

A company, with a capital of £12,000, in £10 shares, has been formed for supplying the city of Ely with gas.

Timber Trade Review.

PRICES 28th February:—Per Petersburg standard.—Quebec pine, 12ft. 3 by 11, 1st bright, 19*l* 10*s*; 1st floated, 16*l*; 2nd bright, 14*l* to 14*l* 5*s*; 2nd floated, 12*l*; 2nd dry floated, 12*l* 10*s*; 3rd floated, 9*l*; 3rd dry floated, 9*l* 5*s*; Sagnenay 1st bright pine, 3 by 11 to 22in., 20*l*; 3 by 9in., 15*l* 5*s*; 3 by 11 to 21in., 17*l*; Quebec 2nd red pine, 12ft. 3 by 11, 12*l*; Saquenay 2nd red pine, 8*l* 15*s* to 10*l*; Jacobstadt 1st millsawn yellow, 9*l*; Onega 2nd white, 8*l* 10*s*; Gefle mixed yellow, 10*l* 5*s* to 12*l* 5*s*; do 3rd yellow, 8*l* 5*s* to 11*l* 10*s*; do mixed white, 9*l*; Hernosand mixed yellow, 8*l* 10*s* to 9*l* 10*s*; do 3rd yellow, 7*l* 10*s* to 8*l*; do 4th yellow, 7*l*; do mixed white, 7*l*; do 3rd white, 6*l* 5*s*; do 4th white, 5*l* 15*s*; Husum 3rd yellow, 7*l* 15*s* to 9*l* 5*s*; Petersburg 1st white, 8*l* 15*s* to 9*l* 10*s*; Pitea mixed yellow, 6*l* 15*s* to 8*l*; Sundswall mixed yellow, 9*l* 15*s* to 10*l*; do 3rd yellow, 8*l* 10*s* to 8*l* 15*s*; Sannesunna 1st white, 1 by 6in., 4*l* 5*s*; do 3rd white, 2½ by 6½in., 5*l* 10*s*; Ulenborg mixed millsawn yellow, 8*l* 10*s* to 9*l*; Uddevalla 3rd yellow, 8*l* 5*s*. to 8*l* 10*s*; Vefsen millsawn yellow, 6*l* to 8*l*; do millsawn white, 5*l* 5*s* to 7*l* 15*s*; Wifsta Warf 3rd yellow, 7*l* 15*s* to 9*l*; Archangel 2nd yellow, 9*l* 5*s*; Bjorneborg mixed millsawn yellow, 6*l* 15*s* to 7*l*; do mixed millsawn white, 6*l*; do 1st millsawn white, 7*l*; do 1st handsawn white, 6*l* 5*s*.

Per 120 12ft. 3 × 9.—St. John's 1st spruce, 15*l* 5*s* to 15*l* 10*s*; Saquenay 1st spruce, 13*l* 10*s* to 13*l* 15*s*; Quebec 1st spruce, 18*l* 5*s* to 18*l* 10*s*; do 2nd spruce, 14*l*; do 3rd spruce, 13*l* to 13*l* 5*s*.

Flooring, per customary square.—Bjorneborg 1st yellow, ⅞in., 8*s* to 8*s* 3*d*; Gothenburg 1st yellow, ⅞in., 8*s* 3*d*; do first white, ⅞in., 7*s* 9*d* to 8*s*; Fredrickstadt mixed white, ⅞in., 7*s*; do 1st white, 1in., 8*s* 9*d* to 9*s*; ⅞in., 8*s* 3*d* to 8*s* 6*d*; do 1st yellow, 1¼in., 13*s* 3*d* to 13*s* 6*d*; 1in., 10*s* to 11*s* 3*d*; ⅞in., 8*s* to 8*s* 3*d*; ⅞in., 7*s* 6*d*.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

Sudbury Waterworks, March 4.—Contract No. 4. Construction of a covered service reservoir. Contract No. 5. Supply, laying, and fixing of about five miles of cast-iron water-pipes, with sluice-cocks, hydrants, and other appliances, and some ironwork required for reservoir. Mr. Hennell, 7, Salisbury-street, Adelphi.

Harwich, March 7.—War Department triennial contract for builders's work. Royal Engineer's Office, Colchester.

Ropley (Hants), March 4.—For the erection of a house and offices at Lyewood, Ropley, Hants, for Mr. John Lilly-white. W. H. Hunt, architect, Alresford.

Norwich, March 7.—War department triennial contract for builders' work. Royal Engineer's Office, Colchester.

Hunstanton, March 4.—For the erection of nave and north aisle of new church at St. Edmund's. Frederick Preedy, architect, 13, York-place, Portman-square, London, W.

Maidstone, March 6.—War Department contract for bricklayers', masons', paviors', carpenters', plasterers', slaters', plumbers', smiths', painters', glaziers' and paper-hangers', and gasfitters' work. Royal Engineer Office, Chatham.

Hinckley Local Board, March 6.—For the sinking of a bore-hole and well, on the site of their intended water-works. Samuel Preston, Clerk to the Board, Hinckley, Leicestershire.

Headbourne Worthy, Hants, March 4.—For the erection of a gentleman's residence and stable buildings, at Headbourne Worthy, near Winchester, Hants. John Dolson, St. Swithin's-street, Winchester.

Fawsley (Northamptonshire), March 13.—For the erection of farm buildings. Mr. Waters, Fawsley Estate Office.

Herefordshire, March 7.—Thornbury United School. —For the erection of a school for fifty-four children, with mistress's residence, at Thornbury, three miles and a half from Bromyard. W. West, solicitor, Bromyard.

Colchester, March 7.—War Department triennial contract for builders' work. Royal Engineer's Office, Colchester.

Portsmouth, March 10.—War Department triennial contract for builders' work. Royal Engineer's Office, Portsmouth.

BANKRUPTS.

(to surrender in London).

Charles Castleman, Westbourne-park-villas, Bayswater, and Kingston, Surrey, timber dealer, March 14, at 11—Samuel Sewell Wilson, Burton-street, Pimlico, builder, March 22, at 12.

(to surrender in the country).

Charles Holman, Kingston-upon-Thames, builder, March 16, at 3—Thomas Pooly, Maidstone, lime merchant, March 10, at 2—John Sturgeon, Bolton, engineer, March 15, at 10—Matthew Henry Tunaley & John Bland, Manchester, joiners, March 30, at 9 30—Charles Wakelin, Bleckney, Leicestershire, brickmaker, March 10, at 11.

public examinations.

March 31, T. Thorogood, Redbourn, Hertfordshire, carpenter—March 9, J. Cropper, Sheffield, plumber—March 8, A. Combes, Tyndale-place, Islington, builder—March 18, H. W. Webster, King's-road, Bedford-row, builder—March 29, T. Cook, Greenwich, engineer—March 15, R. S. Rowlands, Liverpool, iron merchant—March 17, H. J. Ingram, Cheltenham, surveyor.

declarations of dividends

William Moxon, Fulham and New street, Spring-gardens contractor, 2nd dividend of 5 13-32d., March 1.

dividend meetings.

March 14, P. M. Parsons, Arthur-street, West City, and Shooter's-hill-road, Kent, civil engineer—March 14, J. Gullett, Chetwynd-road, Kentish-town, builder.

PARTNERSHIPS DISSOLVED.

T. Corless & W. Fox, Horten, Yorkshire, engineers—J., M., & H. Moody, Clydach, Glamorganshire, brick manufacturers—T. Upton & J. Hardaker, Bradford, stone merchants—J. Pattinson & J. Stewart, Workington, Cumberland, masons—W. Wright & J. Whiteley, Sheffield, joiners—R., D., and G. Davies, Lea-bridge, Middlesex, slate merchants.

THE BUILDING NEWS.

LONDON, FRIDAY, MARCH 10, 1871.

THE ATTEMPTED COUP-D'ETAT AT THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE Members of the Institute, and of the architectural profession generally, will, we are sure, learn with the same regret that we have, that a *coup-d'etat* has been attempted in Conduit-street (we are unable to presage whether it will prove successful or not), the result of which cannot be other than deplorable. The conspirator-in-chief, nay—as it appears, the sole conspirator—is no less a person than the President himself. Some shadowy notice of his proposal was given, it is true, in his opening address at the commencement of the current Session, when he promised that further due intimation should be given of his intentions. No such due notice was, however, our readers will be surprised to hear, vouchsafed either to the Council or the Institute until on Monday evening he disclosed his plot. The propositon, in brief, is that the Honorary Secretaryship for home duties should be at once abolished, that the present paid Assistant Secretary should be raised to the office of Chief (not Honorary) Secretary and Member of Council, to have the sole control and management, under the Council, of the affairs of the Institute, and that the Honorary Secretary for Foreign Correspondence, retained in order that the provisions of the charter might be verbally complied with, should confine himself to the special duties of his post, and consequently be altogether subordinate to the paid secretary. In thus suddenly springing a mine under the feet of the present executive and general body of the Institute, we are bound to consider that the President committed a grave dereliction of duty and abuse of privilege, and acted in a manner the very reverse of courteous to the Institute, the Council, and the present Honoraray Secretaries; and though professedly he has sought the interest of the paid Secretary, a little consideration will shew that this aim he likewise missed.

Surely a step of so vital and revolutionary a character ought to have been submitted in the first instance to the Council, and fairly and fully discussed by them before it was launched before the general body. Again, without doubt it ought not to have been tacked on, as it was, to the fag-end of the notice-paper of a special general meeting, already overburdened with a plethora of important business—in the expectation that the fatigued members at a late hour might fail to see through the insidious nature of the design; and obviously, the Honorary Secretaries, whose posts were so summarily to be dispensed with, ought to have had some apprisal of the manner in which they would be affected by the scheme. Fortunately, although a few too hasty members gave an inconsiderate adhesion to it, the majority wisely required some further time for its consideration; and, as the meeting was adjourned until Monday next for the purpose, we trust they will meet again in a calmer spirit, and view the matter fully in all its bearings.

Before unmasking his battery, the President made a few faint remarks to Mr. Seddon, the Hon. Sec. for Home Duties, deprecating the idea that any personal slight was intended towards himself. No mention of his name, it may be remarked, was made in the opening address alluded to when the outlines of the scheme were first vaguely suggested, although very complimentary language was used towards his colleagues. Mr. Seddon, in reply, said that he would accept the statement, and beg the members to discuss the subject without reference to himself, but upon its own merits, and for the good of the Institute. More he could not well say, as obviously his mouth was closed, and it was not for him to dilate upon the character of the duties of his office, which, in his preamble, the President has declared to be obsolete, or to explain what had been the nature of his services during so many years, as they were now assumed to be useless.

The Hon. Sec. for Foreign Correspondence, Professor Donaldson, Past President, and whose letter will be found in another column, declared that no other course was open to him but to resign office, seeing that it would be thought "honorary without honour" any longer; and expressed his opinion, founded upon a longer experience than that of any other member in the official position referred to, as to the impolicy of the President's proposal.

Since then Mr. Donaldson has sent in his resignation, not only of his official position but of his Fellowship as well; and we deeply regret that one of the founders and best supporters of the Institute should have had reason to feel himself so aggrieved as this step indicates.

Such is a historical sketch of what has taken place at present. The objects and prospects of success of this attempted *coup-d'etat* we are somewhat at a loss to divine.

The President has disavowed all personal consideration in the matter, and we are bound, therefore, to believe him. We are inclined, then, to account thus for the reasons which have led to this extraordinary conduct on his part. On taking office, he deprecated, with expressions of humility for which we give him credit, that the choice of the members had fallen upon himself, as one whose position in the profession did not of itself entitle him to hold it. Certainly we agreed with him on that point; but looking to the parallel case of the Presidentship of the Royal Academy, we thought he possessed many qualifications that might render him fit for the office. He promised, however, that by his diligence to the duties of the Presidentship he would endeavour to do justice to the selection that had fallen on him. In this anxiety to be active there was, as it has proved, much danger. The President should be, no doubt, if possible, a professional man; but, whether or no, his position should be such as of itself to confer dignity upon the post; and such being the case, it is not necessary for him always to be in the chair. On the contrary, it is far better he should not be present too often, otherwise the Vice-Presidentships become merely ornamental nullities, and may in their turn come to be voted unnecessary.

The activity, however, which Mr. Wyatt has imposed upon himself has led him to be ambitious. He would needs be dictator, with a deferential Council, perhaps, but without any other official than himself to originate measures; and a paid secretary to him in this capacity is all that he conceives to be wanted. This ambition further would lead him to achieve the reputation of statesmanship. Alas! that with the recent foreign political *fiasco* to warn him, he should have fallen into a similar snare. But we have said that the very person sought to be benefitted would be rather injured by the movement set on foot in his favour than otherwise.

The purpose of the Hon. Secretaryship is that one Fellow annually elected, and therefore easily removable, should hold office long enough, if his policy be approved, to guide in matters of business a Council composed of ever-varying members, as well as a President, occasionally in the chair, in reasonable rotation with the Vice-Presidents.

An Hon. Secretary is supposed to have a policy, and Mr. Seddon has often avowed his; but a paid secretary, if he would keep his salary, would abstain from one, and not seek to lead the Council; and this Mr. Eastlake has hitherto wisely done. We fancy the uncertainty of a position, salaried, yet dependent by charter upon annual election, and the caprices of what often have proved small, unrepresentative, and party-spirited meetings, will prove but an embarrassing compensation for increased hours. And a paid secretary may find the policy that will be expected of him—at least under a less active President—rather an awkward acquisition.

At the same time, while we think the proposal an undesirable one on behalf of Mr. Eastlake himself, we cannot but think that he might be addressed as Secretary in future instead of Assistant-Secretary—a term which from the first we objected to—although the present injudicious movement may show that it was not adopted without some foresight, and may have had more reason in its favour than we discovered. In conclusion, we own *coups d'etat* are usually condoned if successful, and it may be that we should be wrong in assuming that Mr. Wyatt has in this case reckoned without his host; yet we have a shrewd suspicion that such will prove to be the case.

VIOLLET LE DUC'S "DICTIONNAIRE RAISONNE DE L'ARCHITECTURE FRANCAISE."*

I.

IT is seventeen years ago since the first volume of this recently-completed work first made its appearance. It is a work which forms an enduring monument to the author. Replete with reflections, demonstrating great archæological research, and exhibiting a profound knowledge, both with the theory and the practice of his profession, its completion marks an important epoch in art literature. Very rarely has it been given to one man unaided to fulfil such a task, and the industry and perseverence exhibited here are overwhelming. Ten volumes, extending over 5,000 pages of well thought-out matter, show how enthusiastic and how zealous in his work M. le Duc must have been; and when to this we add the charge of an extensive practice and the publication of those admirable works "Le Dictionnaire raisonné du Mobilier Française," his "Entretieur sur l'architecture," and innumerable brochures, we are amazed, not only that M. le Duc should have done so much, but also that it all should be done so well. Only those who have attempted to write upon such subjects can appreciate the enormous labour of research for materials, the constant and unexpected cropping up of new illustrations which revise—nay, not unfrequently change—an opinion partly formed, and which necessitate a recasting of much already done, can appreciate the work at its full value; indeed, the first words of the first volume inform us that it is the result of five-and-twenty years of previous study. Sure we are that what remains is the precious ore extracted from an enormous mass of crude facts accumulated by patient labour, carefully sifted, sorted, and arranged, and now presented to us a most perfect sample. As an illustration of how great M. le Duc's task has been, let us look at what the aggregate labour of a band—too small a band—of English architects has done. We find the "Dictionary of Architecture" yet incomplete. Many years have run since it was commenced; it is as yet not half finished, and, though good in itself, it is by far less complete, less erudite, and less reflective than this one of the many works of M. le Duc. Add, if you will, the other works on architecture published by any half-dozen of our leading architects, and the aggregated brain-work is dwarfed by the colossal labour of their French confrere. M. le Duc is a giant—he is Argus and Briareus. Will he forgive us for seeking in Pagan fable for this illustration of strength, observation, and labour? His work

* Dictionnaire raisonné de l'architecture Française du XI. au XVI. Siecle, par M. Viollet le Duc, architecte du Gouvernment, Inspecteur-general des Edifices Diocesains. 10 vols.; 8vo: Morel, Paris, 1854—1868.

to us seems so superhuman that we are driven into the dim unrestricted region of myth to find a fitting comparison. Now although the particular work the title of which heads our chapter is undoubtedly well known to many of our readers, there are many—we fear too many—who, from its being written in French, are unacquainted with its text ; and then, alas, too many to whom its price will render its possession impossible. For the benefit of those, we propose to take a somewhat extensive review of it. We shall treat it volume by volume, giving occasionally some reproductions of those beautifully-executed woodcuts which enrich its pages, and for which alone we much fear it is too frequently sought. Often do we see the architectural detail illustrated in it reproduced in the work of our ci-devant Gothicists in utter opposition to the principles inculcated in the text. Such possessors of this excellent work profane it by such treatment; they have not art enough to steal deftly, and when convicted should be doubly punished ; the crime and the blunder both merit such a reward. All such should inscribe over the door of their study, if they use one, these words from the preface of that book they thus abuse—"If we build a new edifice it should serve as a language, to express our thoughts, but not to repeat what others have said." It is well to study carefully M. le Duc's preface—careless readers never study prefaces ; if they only had to write one they would know how much is packed into how little there ; but as no architect has yet invented an illustrated preface, those who only look upon architectural books as marine-store-shops for odds and ends of stolen goods pay no attention to these—and thus, we fear, M. le Duc's preface is almost unknown. We wish that our space would let us reproduce it entire ; as it is, we must only glance at this porch-way, and note some few of the lessons which are taught us on the very threshold.

In this preface our author tells us that after having undergone the two years' regulation wandering and desultory study in Italy, he returned to France, and though he in some measure before appreciated the edifices of his own country, he was more and more struck with the aspect of them, with the wisdom and science which had presided over their execution, and the unity and harmony of method followed in their execution and their ornamentation. Already distinguished men had paved the way to their study, lighted on their road by the works and admiration of their neighbours the English. They dreamt of classifying edifices by styles and epochs; they did not follow texts, for the most part erroneous, but they admitted an archæological classification based upon the observation of the monuments themselves. The first works of M. De Caumont brought to light the well-marked characteristics of the architecture of Northern France. In 1851, M. Vitet addressed to the Minister of the Interior a report upon the monuments of the departments of the Oise, the Aisne, the Nord, the Marne, and the Pas du Calais, in which this elegant writer drew the attention of the Government to the unknown treasures which were at their very doors. Still later, M. Merrimée followed out the researches so happily commenced by M. Vitet, and wandering over all the ancient provinces of France, saved from ruin numbers of edifices which no one then cared for, and which form to-day the riches and the pride of the towns which possess them. M. Didron expounded the painted and the sculptured poems which covered the cathedrals, and drove away those vandals who would destroy them. "But—and we say it to our shame—our artists remained behind, and our architects rushed off to Italy, never opening their eyes until they reached Genoa or Florence, and came back with portfolios filled with sketches made without criticism and without order. They set to work at once, without ever having set foot on an architectural monument in their own country." Such is the brief history of the rise of the "Gothic mind" in France. There, too, we see that painting and architecture were the last arts to receive the impression of the time. They were not vernacular arts, and we much fear that it is the same now-a-days. If we regard the origin of this feeling in our own country, we shall see that it paseed through the same phase. Horace Walpole and Sir Walter Scott initiated the study of Mediæval art ; Chippendale made eccentric furniture ; and Rickman, a quaker linendraper, classified our ancient buildings under a titling of inexact nomenclature ; but our architects studied Taylor and Cresy, were learned in Stuart and Revett, and the buildings of our own country were left equally disregarded. Then arose Pugin, a foreigner, and, therefore, an appreciator of English art ; and, last of all, when Pugin found patrons, and his son became successful, our architects awoke to the fact that it paid, and studied it a little also. English art has, however, found no such exponents as has French art. Even yet we have no rudiments of archæology published in an inexpensive form for the use of schools ; yet the admirable "Abetcedaire d'Archæologe" of M. de Caumont bears date 1850, and has passed through many editions. It is true the works of Pugin, Britton, Sharpe, and Bowman have nobly illustrated many of our finest Mediæval buildings, but they are dry lines only without clothing—no reasonable text relating to the theory and practice of architecture as an art. Picturesque delineation and romancing histories of our old buildings filled our bookcases, and were mistranslated into stucco and novels accordingly. The west front of York Minster was boiled down to the elevation of a Dissenting chapel, its beauties and its teachings evaporated, and a bleached and tasteless extract served up. Our old churches and cathedrals are "restored" out of knowledge and destroyed at five per cent. ; and our architects rush off to France, to Italy, to Germany, bringing back neat volumes of closely-drawn lithographs, which are subscribed for at a high price, and afterwards tried to be sold at a little one ; but careful investigating study of our own Mediæval architecture has, as yet, found little or no place in the profession. Let us listen to M. le Duc ; let us hear how he set about to study the home treasures with which he was surrounded. "In the work which we publish to-day we have essayed not only to give numerous examples of the diverse forms adopted by Mediæval architecture, according to a chronological order, but we have, above all, striven to make known the reasons why it assumed these forms—the principles which led to their adoption. To us it appears difficult to record the successive transformations of the arts of architecture without giving at the same time a sketch of the civilization which enveloped them, and if the task should be found too great for us we shall have at least done pioneers' duty for our successors; as for us, we cannot study the garment without considering the man who wears it." Alas! what a lot of tailors there are amongst architects now-a-days. But our master is speaking, so we will be quiet. Listen ! "Now all sympathy for this or that form of art put aside, we have been struck with the complete harmony which exists between the arts of the middle ages and the spirit of the peoples in whose midst they have developed themselves. From the moment when Mediæval civilization found itself living and organized, it progressed rapidly." "It is not to-day only that western Christianity has inscribed on its flag the word —Progress. Who speaks of progress speaks of labour, of struggle, and of transformation." That is a truly philosophical view of the records of a nation's history by its arts, but unfortunately the converse does not hold good. We have struggling, and labour, and transformation enough and to spare in art, and especially in architecture now ; but unfortunately it is against, not for the spirit of the time, and progress is not the result. Do "Gothic" theatres and law courts, Renaissance tabernacles, and torturing brick churches of no style, expressive of no sentiment, mark progress ? Do girder bridges or cast-iron arched ones mark progress ? Do buildings which show how many books a man has on his library shelves, and how few brains he has in his head, show much progress ? Alas no ! Until common sense rules, until common wants are expressed in a common language, we shall have no progress, and the architecture of this day can create but a valley of dry bones so long as it borrows these bones only from the past. It props up the dead body, but it instils no life ; it studies consequence only, and disregards the cause, and for this reason it has ceased to be an art, and degenerated into a trade with 5 per cent. profit and a discount off. So far it certainly represents the commercial spirit of the age, and thus far it is true. But is that a fine art ? In reviewing M. le Duc's account of the duties of an ancient architect, we shall have to speak further on this point, so at present we will say no more. We regret we cannot agree with him in his contrast between the ancient civilization, and that of the epoch he treats of. Like most enthusiasts, he can only see one side of the question ; he sums up the difference between the two by calling the former absorbent and the latter expansive. To our minds like causes produce like effects, and to a certain point each phase of art has trodden parallel paths ; each has its absorbing, each its expanding time, as the political and social history of its time varied ; and the arguments in favour of any one particular phase of art expression is equally applicable to a correlative period in the course of the other. Absorption is simply taking in food for expansion, and when any style of art has ceased to absorb the feelings of its time, if it does not expand it withers away and dies.

LINCOLN'S INN.

A CORRESPONDENCE has lately been going on in the *Times* respecting Lincoln's Inn and Lincoln's Inn-gardens. "A Junior of Twenty Years' Standing" opened the ball by announcing that a new set of chambers is to be erected in the garden of Lincoln's Inn. The veteran junior says that these chambers will be too far from the New Law Courts to be convenient for barristers, and he intimates that if the recommendations of the Judicial Commission are adopted there will be local courts, and the courts of appeal only will sit in London. "A Bencher," in reply, says that "the Bench have not resolved to build the chambers in the garden," and that the hoarding was put up "to enable us to gather opinions as to the alleged expediency of so sacrificing the garden to meet the alleged want of chambers, and to enable us quickly to rebuild the almost ruinous 'Old-buildings.'" The *Law Journal* thinks this answer of the Bencher fully justifies the warning of the Junior. In the case of bricks and mortar, it says, the first step, though experimental, is too often the beginning of the costly and ruinous end. Putting up the hoarding to try the effect is an ominous proceeding, and a word of caution is not out of season. No doubt there is a great demand for chambers, and the Benchers ought to do what they can to meet it. We should have thought that Old-buildings might be gradually rebuilt without the prior erection of new chambers. In these days building work is done quickly, and barristers might be content with chambers out of bounds during the time of rebuilding. We trust that, whatever decision is arrived at, the garden will not be spoilt by the erection of a new set of chambers, and that the hoarding will be speedily removed.

On dit Sir Robert Peel has sold the valuable collection of pictures, chiefly Dutch and Flemish, which his father spent so many years in accumulating, but which he himself does not profess to have especially admired. It has been purchased by the Trustees of the National Gallery for a sum of £75,000.

THE PATENT LAWS.

NOT fewer than three Bills are before Parliament proposing to modify or abolish the Patent Laws. The cry for repeal has, for many years, come from the same quarter, and it is still contended that the abolition of patents would conduce to the advancement of arts and sciences. On the other hand, it is urged that this would put a deadlock upon the genius of invention. Now, between these two extremes, may we not find a middle term, as in logic? And, if not a middle term, then we are forced back upon the principle of patents. There are economists who protest against "property in ideas;" who would disendow the human mind; who would treat the contriver of a new machine as the Americans treat the author of an English book—thank him for his production—and steal it. A patent is granted for the mode, easier and cheaper than other modes, of achieving a particular result. It is as much the individual's property as an artist's picture or a scholar's book. Take the method of boiling; you cannot patent heat, but you can patent the means of applying it. It is to the parts employed in working out the discovery that the Act of Parliament affords protection. When Mr. Smith patented the screw propeller he did not become possessed of the sole right to the idea of propulsion by means of a screw; other inventors obtained patents for varying patterns. So with the paddle-wheel. The feathering superseded the fixed float, and no legal privilege was infringed. But the extinguishing of this privilege would be the deadening of independent ingenuity. Who cares to work without a reward?—Who, especially among the poor, whose dreams, while they ply at their striving labour, are of reputation and success? As well might men publish books without copyright. An invention is not a commodity which can be produced at will. If we wish to have bread to eat we must till the ground; if we have corn to grind we must send it to the miller; we must sow the seed, reap the harvest, separate the wheat from the chaff, convert the grain into flour, and the flour into dough, and the dough into rolls and loaves; and we have the needful substance on our tables. But we are bound to think of the miller and his men. For centuries, dating from beyond Chaucer, they toiled in an atmosphere made unwholesome by the cloud from the grinding grain. Then stepped in the inventor, Bovill. He had devised a plan for increasing the efficiency of the millstones, while subduing the mealy dust. He patented it. But what the outcry? Exactly that which greeted Christopher Columbus when he had found out a new world. Anybody might have done it. Each miller could have made the discovery for himself "in process of time." But the process of time is a long one, occasionally. Three-fourths of the millers in England, for many years, neglected Bovill's improvements, as three-fourths of the engineers despised Watt's modifications of the steam engine. An eminent lawyer recently said—and it was a surprising thing for him to say—that all inventions will be made, some day or another, even if the patent laws are abolished. This we can neither disprove nor accept without qualification. The qualification is that Patent Laws are good, not merely because the direct influence they have in the stimulating of invention, nor even that they act, in a manner, as premiums upon ingenuity, but because, when the State has to deal with the demands of inventors, and has to take into account the interests of every section of the community, patent laws offer the most equitable arrangement for satisfying rival claims, while protecting the meritorious from pillage and ruin. It is urged that the laws of nature are common property. But is a peculiar insight into these laws common property? We do not suppose that Newton ever thought of patenting his law of gravity, or that a mathematician who squared the circle would register his triumph at the South Kensington Museum. Still, in our day, thousands upon thousands of discoveries, useful in their way, are the productions of poor men's thought, who cannot afford to give their time to enrich "the general fund of the world's wisdom." They do not ask for a perpetual prerogative of royalty in a screw propeller, an hydraulic press, a steam engine, or an electric telegraph; they want, in plain language, to gather in the first fruits of their intellectual industry; and they have a right to it. Why should the dull and indolent profit freely by the exertions of the acute and pertinacious? Where, under those circumstances, would be the natural human motive for exceptional effort? It is very easy to talk about the sacrifice of a few to the general good; yet where would the few be found unless they felt an incentive? It has been wisely written there is in reality no great and continuous labour undertaken without some stimulus of a more special and personal kind than the self-satisfaction of contributing to the enjoyment or profit of our mortal race. We all denounce when a great inventor dies unrewarded. He has been looking keenly into the laws of nature; he has learned something of which we, hitherto, have been ignorant; he has won in a race for which many have started; and, forsooth, he is to be denied the prize because others might equally easily have won it! For our own part, we can perceive no tangible distinction between copyright in a book and copyright in a mechanical or scientific invention—setting aside discoveries in surgery and medicine, the disclosure of which is immediatly due to all mankind. We cannot distinguish between the author of a work on the screw-propeller and the author of the screw-propeller itself. The book is a creation, and the novelty it treats of is an invention also; and why should not both be a protected? The history of discovery is a history of surprises. We do not say that Patent Laws are never abused. They are put in force for un-meritorious quackeries, and for copies of old specifications. But these abuses, upon the whole, correct themselves. There is no virtue in the words "by royal letters patent" which can permanently mislead the public. If these words were legally affixed to machines constructed to produce perpetual motion they would hardly suffice to overcome those drawbacks due to friction and gravitation which have always hindered such engines from working so well in practice as they do on paper. Patents, justly understood, are the finger-posts of progress. They are granted upon exactly the same principle as that which created our Indian and North American Empires. They are related to the spirit of monopoly, no doubt; but is not every man's private estate a monopoly? Is not every man's personal genius a monopoly? Was not Sir Walter Scott—was not our Charles Dickens a monopolist, in the most exclusive sense of the term? There is nothing in common between these particular prerogatives and, for example, the infamous monopolies created by Queen Elizabeth. The sovereign has no longer any power to bestow these rights. If they are falsely-claimed, they can be cancelled; if they are grossly absurd, so as to include, at once, the propelling of ships, the making of shoes, and the cutting of turnips, they are, no matter what fees are paid, null and void. Still, we admit an injustice and a difficulty. Men who can really invent nothing, may be able to suggest a slight improvement, actually suggested by some other man's work, the work of an original and fertile brain. Here the patents compete unfairly: the greater gives way to the less. If a man discovers the effect of the actinic rays of light on nitrate of silver he becomes master of a new idea, and may, by publishing his discovery, make the public share in his knowledge. Another individual takes advantage of it, and produces a picture on a piece of glass or a sheet of paper. Or the the one finds a bed of iron-stone or a seam of coal, while the other contrives an apparatus for smelting. Which should be the patentee? Which should possess property in the idea? Clearly the one who can practically apply it. The discoverer enlarges our knowledge; the inventor increases our power; and the whole case stands this way: some manufacturers complain that they are hampered by patents, that they know not what to do lest they should infringe the rights of some monopolists, whom they cannot compel, under any royalty, to grant a licence for making their apparatus or employing their process. Against all this we have only to plead again that industry and ingenuity must have their inducements and their rewards.

ROAD-SCRAPINGS *v.* "HOGGIN."

THE enormous cost of keeping in repair the many hundreds of miles of roadway comprised within the metropolitan area renders it necessary that the greatest economy, consistent with efficiency, should be exercised by the surveyors to the various vestries. In the streets subject to a heavy traffic a sharp contest has for some time been going on between asphalte and granite "setts;" but whichever of these two methods of paving is found, after thorough trials of each under all conceivable circumstances, to be the most suited for what we may call "city" traffic, we suppose that in the long lines of road abounding in the suburbs, granite, macadam, and flint roads will still hold their own, especially now that the steam-roller is beginning to be more widely appreciated by those slow-to-move bodies the vestries. With the aid of the steam roller a macadamised road may now be made smooth, hard, and infinitely more durable than when cart and omnibus wheels and horses' feet are made to do what should be done by the roller. But the old method not only entails cruelty to animals, it takes more money from the pockets of the ratepayers; for roads made in such a barbarous fashion always wear very quickly into innumerable holes, and require "mending" incessantly. By using the steam roller the cost, though perhaps greater at the outset, is less in the long run, for steam-rolled roads wear smoothly and evenly, and require little attention.

In the use of the steam-roller it is found advisable to use "hoggin," a sort of sand or fine gravel, as a binding material, and it has been more than once suggested that the scrapings of the roads, especially of those made of flints, could be profitably used as "hoggin." We are glad to see that at the last meeting of the St. George's, Hanover-square, Committee of Works, the surveyor (Mr. Tomkins) reported that he had made inquiries as to the means of disposal of the road sweepings in the various metropolitan parishes, and as to a suitable site for the storage of a portion of the road scrapings to be used in place of "hoggin." He had written to every road surveyor in London, asking two questions—1st "How do you dispose of your road sweepings?" and, 2nd, "Have you used any portion as a substitute for "hoggin," and, if so, with what result?" He had received answers from thirty-one surveyors, of which he gave a summary. Twenty-six stated that they disposed of the sweepings by contract, the contractor being paid for their removal. Eleven stated that they had used road scrapings instead of "hoggin" with good results. They did not, however, specify whether from granite or flint roads. Five stated that they had used scrapings from flint roads only. Four had never used them. Three consider them useless. Two consider that they should be used with caution. Three preferred "hoggin." Four sold their scrapings for manure. There was, therefore, a large majority in favour of the use of road-scrapings as a substitute for "hoggin," and his opinion was favourable to their being so used, while at the same time he fully agreed that it should be done with caution. To obtain good results they should be used when the weather was dry. He was of opinion that only flint scrapings should be used. Granite scrapings consisted of a fine powder, containing a large percentage of organic matter, whilst flint scrapings consisted of loamy grit containing a much smaller percentage of organic matter.

A new town-hall is to be built at Madras. The Vizianagram gives £1,000 towards it.

SUN-BURNERS.

(Concluded from p. 141.)

THE next point to be attempted in order to render the sun-burner better adapted for universal domestic use is to reduce the heat given out by the lamp itself. The larger jet at a lower pressure will somewhat help this, and the shape of the elongated case, and consequently larger air space between the light and the atmosphere of the room, will still more materially assist, but the most certain aid will be in a more thorough and extensive ventilation of the ceiling of the room itself. As rooms are now usually built, ventilation other than that afforded by the fireplace (often closed with a register) and the occasionally opened window is rarely attempted, and spite of all that has been written, said, and done, architects and builders still go on in the same unscientific, unreasoning way, and build walls for warmth and glazed apertures for light, and let fresh pure air—the first essential of comfort—take its chance. In a former paper, a simple addition in the ordinary manner of constructing a drop-light window frame was pointed out (see the Building News for December 23rd, 1870, p. 459), and which at such times as the crowded state of the room rendered the heat more than usually intolerable, might afford a most grateful relief; but in addition to this, in contriving for the introduction of a sun-burner, and indeed for the use of any other artificial light, an ever-acting escape of heated air must be provided as the very first essential. To do this, the very source of the trouble—the heat from combustion of the gas itself—can be used as the motive power of cure. In all flues intended to carry off heated air into the colder external atmosphere, the great obstacle is the down-draught; and numerous as are the appliances in shape of valves and chimney terminals to remove this, scarcely any one of them is certain or satisfactory. It should, perhaps, be stated that the American pattern known as Emerson's ventilator, which is simple and scientific in its primary principle, is the most effective apparatus for the purpose of an external wind-guard, and as it is probably but little known here, its form and action may be briefly described with practical advantage. It consists first of a base or wind-box above the roof, of any suitable size, provided that the square of it be larger than the diameter of the shaft or flue, and its height not less than one diameter. From this rises the shaft, of not less than five diameters, and at top of this is a truncated cone formed by a sloping rim pointing downwards at an angle of 45°, and with a perpendicular height equal to one diameter. The space between the lower edge of the rim and the shaft is filled in with a disc of sheet iron, leaving the form of the cap so far that of a truncated cone. At the height of one diameter from the open top (which is of course the top of the tube or shaft itself) is a circular flat of stout zinc or iron exactly the size of the base of the cone; this is supported upon any sufficient number of metal rods rising from the lower edge of the cone, and is simply to protect the mouth of the flue from rain or direct down-current. The action depends upon the movement of the atmospheric wave across the top of the opening, and with the very slightest movement (which above a roof is almost invariably present) a vacuum is created in the upper part of the shaft, and consequently an upward direction is given to the flow of the column of air within the flue itself.

With such a terminal as this the escape of heated air from the gas flue will be assisted, but it will not always and under every condition of the atmosphere be a perfect result; to ensure a constantly satisfactory ventilation something more must be done, and provided that the flues are of proper capacity, are smoothly finished internally, avoiding as far as possible abrupt angles, and are kept secure from external chill by being cased (when of metal) on their points of exit above the roof, the following plan will be found to answer: Divide the whole of the flues, from their commencement immediately above the burner to their discharge into the air-chest under the chimney terminal, into two equal parts by a diaphragm partition extending the entire height of the flue. The precise explanation of the law which governs the action of this very simple arrangement can scarcely be clearly made, but its efficacy is undoubted, and any one may convince himself of its truth by a simple but conclusive experiment. Light a piece of thin paper and drop it into a wide-mouthed, dry, and empty glass bottle (a water bottle for instance); have ready a strip of thin card-board or stiff paper that has previously been cut to exactly fit the neck of the bottle, and when the flame is just upon point of expiring in the vitiated air of the bottle, insert this card, and at once the flame will return to its pristine brilliancy and continue until the paper is burnt out. The deduction from this fact is that there are opposing currents in every enclosed column of air, and the card acts as a partition to divide them, admitting on the one hand of the upward escape of the foul super-heated air, and on the other of the downward stream of fresh pure air to feed combustion. That there are upward and downward currents of air in ordinary smoke-flues, chimney-doctors no doubt have some experience, but no one yet seems to have attempted an easy and probably always certain mode of preventing what are called smoky chimneys, by building flues sufficiently large to admit of division by a thin metal or ceramic partition into equal parts throughout their entire length. A sun-burner having a flue so made would possess advantages so decided that the additional expense (naturally capable of appreciable reduction as the apparatus became in more general use) would not be considered objectionable by most purchasers or occupants of a comfortable dwelling.

It will thus be seen that many changes have been made in the apparatus since its first introduction to the public, but no marked improvements have been made in any other than the large machines suited to club-houses, theatres, and the like; the small globe-light for ordinary domestic use remains as ugly and clumsy in form as when first introduced. It is somewhat remarkable, by the way, to observe how uniformly clumsy glass globes of English make are compared with foreign; our glass-blowers invariably flatten them at the poles, whereas a French or Belgian workman gives them another swing or two so as to slightly elongate the apex—in this respect unconsciously following the well-known practice of early Greek art-workers, who corrected the optical defects of outlines by just such a divergence as brought the object back to the form intended to be seen. Occasionally an oval has been substituted, but seemingly the gooseberry has been taken for a model, and its poles are as oblate as the globes; probably a bell-shaped form, filled at bottom with a flattened curve cut as a star, would be found pleasing and convenient.

There are no interesting examples of specially decorated ceilings in rooms or buildings lighted by sunburners. On a flat surface, the objection made to them was at first the shadow cast from the bulky tube and heavy frame of the apparatus; but since the introduction by Messrs. Strode of glass and mica into their manufacture, its force has been materially lessened. The form of the burner itself has been improved, and decoration has been introduced; but there are at this present time no examples of an attempt to utilize the brilliant light thereby obtainable as a means of producing legitimate effect. The first point that occurs is the fact of the luminous area immediately around the burner; this could be turned to good advantage by introducting flat decorations in pure masses of light tints relieved by finer lines or portions of positive colours upon a gold ground, repeating the leading characteristics of the design upon the outer boundary of the ceiling near the cornice, and filling the rest of the surface with such neutral tints relieved with diaper, floral divisions, bands, or other carefully arranged designs, as would not prominently catch the eye; making, in short, the burner, with its intense briliancy, the central feature of the composition. In domicular or coved ceilings, the modes of treatment do not seem so difficult, and generally radiating bands of marked design and colour starting from a harmonious centre, and united by similarly disposed designs in the coving or cornice, would be found an effective and agreeable system of decoration. Occasionally the sun-burner may be turned to advantage for the illumination of perpendicular decorations, as in the lunettes under the voussoirs of coved ceilings; for instance, those under the dome of the Gaiety Theatre, which have been so artistically embellished by the designs of Mr. Marks, and for panelled compartments of a frieze; and when the architectural decorations of the building are thus arranged, the position of the source of artificial light lends valuable aid.

The ceiling itself is, however, the natural surface for decorative display; and bearing in mind the necessity of keeping all embellishment subordinate to the overwhelming brilliancy of the central object, an artist should have no difficulty in treating it effectively. There are but two modes of treating a flat surface high over head; one, by making a mass of minute details so evenly balanced as to give the effect of a rich simplicity equal in one sense to that obtained by a general tint; the other, to draw the eye by lines, and bands, and groupings of embellishment, to culminate at last in one great mass of decoration; the sun-burner imperativeiy demands the latter.

REMARKS ON SIR CHRISTOPHER WREN'S CHURCHES.*

THE churches of Wren are almost invariably on the Roman model; wherever the forms of the Pointed style are attempted they are treated in a dead and lifeless manner, and show that the author had an ill-concealed contempt for the Mediæval churches, which he never condescended to study. Previous to the Great Fire, he was consulted as to the reparation of Old S. Paul's, and in a report which he made as Assistant Surveyor-General he says:—"It will be as easy to perform the work after a good Roman manner as to follow the rudeness of the old design." Look at S. Michael's, Cornhill—professedly designed after the noble chapel tower at Magdalen College, Oxford; how thoroughly Wren has succeeded in depriving his imitation of any part of the life and beauty of the original. Look at St. Dunstan's-in-the-East; what a curious admixture of the Gothic form with Roman details, and how feeble the result. Look at the western towers of Westminster, requiring no criticism from me before an educated audience.

The plans of the various churches erected by Wren were simple and uniform when the form of the site permitted; and when, as was frequently the case, the peculiarities of the ground and the angularity of the streets rendered it necessary, it is interesting to observe the ingenuity with which Wren accepted the difficulties and solved the problem. This is emphatically observable in S. Benetfink, Threadneedle-street, where the interior polygonal shape, conforming to the boundaries of the site, has been treated in a most masterly manner. But where practicable the plans of his churches were simple. The principle he laid down is stated in a letter to a friend which he wrote in 1708, respecting S. James's, Westminster, which he thought one of his best works. In this letter he says:—"The churches, therefore, should be large, but still in our Reformed religion it should seem vain to make a parish church larger than that all who are present can both hear and see." "The Romanists, indeed," he goes on to say, may build larger churches; it is enough if they hear the murmurs of the Mass and see the Elevation of the Host, but

* By F. J. Francis, F.R.I.B.A. Read before the Architectural Association on the 24th ult.

ours are to be fitted for auditories." For breadth and simplicity of arrangement, and as realising this leading principle, I may refer to S. James's, Piccadilly, S. Andrew's, Holborn, S. Clement Dane, Strand, S. Lawrence, Jewry, and S. Bride's, Fleet-street.

But passing from the plans and considering the outline of his churches, I hope I shall not be considered guilty of any impertinence towards this eminent man if I say they possess in this respect very few claims to admiration. The most observable feature is that in the majority of cases the exterior is subservient to the interior. The confined nature of the sites on which these London churches were built rendered the architect comparatively indifferent to the form and outline of their elevation, and induced him to throw all his skill and energy into their interiors. The beauty of some of these is only equalled by the contrasted ugliness of the exteriors; and there is many a form which satisfies the eye when you enter the church which has been achieved at the expense of external beauty, and which results in a most uncouth exterior. In proof of this I may refer to S. Mary-le-Bow, Cheapside, S. Stephen's, Walbrook, and S. James's, Piccadilly, where the architectural critic will find abundant proof of what I am stating. The most unsatisfactory features in Wren's churches are the windows. They are tasteless, exhibiting no variety of design—mere miserable gaps in the masonry, glazed in the most ordinary manner. The campaniles have been variously estimated, according to the predilections of the critic, but setting aside the far famed steeples of Bow Church and S. Bride's—the former of which has considerable claims to intrinsic beauty—the remainder of his towers are either square and massive, without relief or variety of design, frivolous in conception, as at S. Stephens's, Walbrook, or the mere piling of order upon order in incongruous ingenuity, as is observable in Christ Church, Newgate-street, and S. Clement Danes. I ought to add that in the interior outlines of many of his churches he was, owing to his scientific knowledge of carpentry, especially successful. The absence of any tie-beam across his larger structures, and where there is a triple division into nave and aisles, is very skilfully compensated for by the triangular construction, bringing the main support upon the nave columns, and thus counteracting the lateral thrust. This arrangement left him free to throw waggon-headed ceilings over the main body of the fabric, added to the height, and considerably augmented the internal grandeur of effect. Some of the ceilings of Wren's churches are well worthy of study—not as models for ecclesiastical structures, for their outlines are now relegated to the theatre and music hall, but as developing new and original forms, curious adaptations of the dome, the vault, the intersecting groin, and the waggon-headed roof, and all remarkable for that exhibition of sound and scientific carpentry which enabled him, without hesitation, to carry out his designs, knowing that structural weakness or settlement was well-nigh impossible.

In details, the review is favourable, so far as interior effect is concerned, though the praise must be confined to a few of the altar-screens, the pulpits, and sounding-boards, and the entrance porches. The style forbade any free and generous treatment, and a cold and cheerless respectability was the chief characteristic. The fact was that the fine arts had withered under the blasts of civil war, and the subsequent contests between their enlightened friends and bitterest enemies had well-nigh rooted out all appreciation of their beauty from the land; and this state of public feeling is only too truthfully represented in the details of the churches we have been considering. Had Wren lived in a different time, and under a better diffusion of the Church element, no one can say how different might have been the bias of his intellect, or from what other indigenous sources he might have drawn his inspiration. But the question forces itself upon us—If Wren was confessedly a great man; if his works are deserving of study; if his churches have had their successive bands of faithful admirers, are they suitable as models for our imitation? Are they in any degree equal to the corresponding examples of the Pointed style which are scattered in such rich profusion throughout the land? I think the answer to both these questions must be in the negative. The dead forms of Pagan art, dissociated from the prevalence of the sister arts which distinguish the Italian types of this Classic style, fall lifeless upon the taste of the present day, and have well-nigh passed into extinction. I feel as I gaze upon Wren's churches, or study their details in the exhaustive work of my late friend, Mr. Clayton, that I am not dealing with an architecture which has any continuous vitality, but with one which has hardly passed above mediocrity (not including S. Paul's) even in the hands of the eminent man under notice, and which in the hands of imitators and successors becomes absolutely contemptible. Models for our imitation these churches never can be. We may reverently admire the varied gifts of Wren—his constructive genius, his mechanical skill, his self-denying devotion to his art, his unvaried integrity; but there is not a young architect before me just entering upon his career who would think of sitting down to study the design of a church with the forms and outlines of Wren's structures in his mind. And in reference to the other question, as to their equality with the noble specimens of Mediæval art, the reply must be equally distinct. There can be no comparison in beauty, because there is none in the principle which originated the rival styles. Sir C. Wren and those who worked out the Roman style took up an alien architecture never naturalized among us, having no congruity with our earlier religious national life, and lacking all association with the centuries which had gone before. It was an architecture of the library and the man of letters, not the architecture which represents the outflow of a great religious principle, under whose festering care the successive forms of the style had been nurtured, developed, and refined. Equally susceptible of convenient arrangement as its Classic rival, the Pointed style appears to exhibit manifold and varied beauties, and in the types of these material forms our admiration is mixed with wonder when we compare the results with the general state of society and education, as contrasted with that which prevailed in the time of Charles II. and his successors; for it is to be observed that the perfection of this art, as contrasted with Wren's, was achieved not amid the prevalence of national taste, the general spread of intellect, the general thirst and desire for knowledge. It rears its stately proportions during an epoch when the mass of the people were uneducated—when the practical and humanising effects of civilisation were but little appreciated; at a time when war usurped all the thoughts of the monarch, when the struggle for power by the lords of the soil forbade any attention to the fine and elevating arts, and when the comforts of family life were so little known that the squires of the day were lodged vastly inferior to the humblest occupants of a suburban villa; when furniture was almost unknown, when even glass windows were treated as tenants' fixtures, and were removed from one house to another along with his other goods and chattels. The truth is that the very principles of the Church of the Middle Ages were directly calculated to bring out and perpetuate these magnificent results. To erect temples to the Divinity was considered the noblest work in which man could be engaged; to lavish in their erection everything that devotion, skill, and genius could suggest; to levy contributions on every side, and promise the rewards of heaven to the most generous; to make the beauty of the material edifice subserve the working out and completing of a vast spiritual mechanism, in which the only two things seen were authority on the one side and submission on the other—these were the distinctive features of the Church of the time, and thus in their buildings they carried out and fulfilled what the ancient Churchmen considered their legitimate and august mission. The ecclesiastics of the time were the master-masons or architects of the time; their names are for the most part lost to us, but there is no doubt that those who evolved these many forms of beauty from material things associated themselves together in one grand confraternity, dispensing to each other the secrets of their art, but never betraying them to the outer world, wishing not to gratify personal feelings or minister to individual vanity, but in accordance with the unbroken line of those traditional associations by which the Church itself was held together, and to consolidate, through the unity of the structures they raised, the strength and power of the great system of which they were the associated brethren. I must not pursue this line of thought further, but I submit it to you as accounting in great measure for the superiority of the national architecture over that practised by Wren—as explaining the enthusiasm created by the one, and the neglect which has fallen upon the other. But as a final word, allow me to say that while we must be careful to avoid narrow and contracted views in estimating the relative value of both Classic and Gothic models, we need not hesitate heartily and earnestly to express our preference, and to work energetically, for the development of that which in our judgment presents the only true ideal of form and design.

DISCUSSION.

The President, in inviting discussion on the paper, observed that it was remarkable how much work Wren accomplished, and what quality and thoroughness it exhibited, taking into consideration the circumstances under which it was produced. He built fifty-one great churches, besides the Cathedral, and a large number of secular buildings. After referring to Wren's rejected plan for the rebuilding of the city after the Great Fire, Mr. Watson spoke of the extraordinary genius and scientific attainments of the great architect, observing that his knowledge of mathematics suggested the question how far mathematics were necessary in the architectural profession, and whether they were not too often thrown aside for the mere artistic branches of study?

Mr. G. R. Redgrave proposed a vote of thanks to Mr. Francis for his paper, which he thought rather under-rated the work of the Renaissance in England. He was glad to find anyone bold enough to say that Wren's churches were ugly, for they were very ugly (laughter), built without any pretensions to façades. It was stated that some of the best spires of Wren's churches were designed by his daughter, notably those of S. Clement Dane and S. Dunstan's-in-the-East, the well-known spire of the latter church being supported by flying buttresses. Although much of the work of Wren's churches must necessarily have been designed by his assistants, yet they exhibited remarkable variety of design, and did not appear to repeat themselves; but to criticise his works in detail, the "Battle of the Styles" would have to be renewed.

Mr. Paget, in seconding the proposition, said that at the present time, when Mediæval architecture was almost exclusively studied, Wren's work would well repay any attention bestowed upon it. He condemned many of the so-called "restorations" of Wren's buildings which had been carried out during the last few years. The idea of restoration was not now so much to restore a work to its original state as to substitute something new. He believed, however, that the way in which the work at All Hallows' Church had been carried out furnished an exception to this rule. He deprecated the use of tracery in the restoration of such buildings, even when (as Sir Digby Wyatt had suggested in the case of S. Lawrence, Jewry) it was of wood, although in the latter case it interfered less with the character of the windows. He thought that Mr. Francis had scarcely done justice to Wren in saying that his windows did not exhibit variety of form. A great perversion had been made by the use of tracery in S. Swithin's Church. Mr. Paget warmly commended the woodwork and ironwork of Wren's churches; much of the former was ascribed to Gibbons. He thought that Wren's spires were very beautiful, those of Bow Church, Cheapside, and S. Magnus, at London Bridge, being good examples. Wren also exhibited the hand of a master in the way in which he grouped his spires round the great dome of S. Paul's.

Mr. Lacy W. Ridge thought that the steeples of Sir Christopher Wren had not been treated with the consideration which they deserved. The huge roof of the Cannon-street station had to a great extent marred the view of them which was to be obtained from the bridges. The steeple of St. Mary-le-Bow, Cheapside, was extremely beautiful, and sprang from a splendid tower, and in this age of finicking details, when each little church and chapel must have its turret and tower, it was quite a treat to meet with a good square stumpy tower (laughter). In Italy the towers were frequently without buttresses, and such examples were well worth attention. He disagreed with the opinion that in restoring a building an architect was bound to adhere absolutely to the original design; that was an archæological notion, and he was persuaded that archæology would be out in about fifty years (laughter). He thought that where a design was bad it should be improved. He disagreed with the author of the paper in the opinion that the original design for S. Paul's was deficient to the one carried out in its provisions for accommodating a congregation. His (Mr. Ridge's) opinion was that the first design was preferable.

The President, in putting the vote of thanks expressed the opinion that S. James's Church, Piccadilly, was one of Wren's best churches, inasmuch as was said to be capable of holding two thousand persons so that all could hear. The motion having been carried by acclamation,

Mr. Francis, in returning thanks, incidentally stated that Wren's remuneration did not exceed £200 per annum. As to the suggestion that some of the details of Wren's work might legitimately be altered, it might be asked whether the architects who contemplated such alterations were always competent to undertake them? And if they were to begin to remodel where would they be able to stop? In conclusion, Mr. Francis expressed the hope that some of the members would find an opportunity to visit All Hallows' Church.

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page* 160.)

Plate 24.—Construction of Wreath from Rake to Level.

Figures 1 and 2. These plans exhibit a straight flight of stairs, landing on a level floor. Both cylinders have equal diameters. That on right shows face of riser standing on the spring-line, whilst that on the left is made to stand back in cylinder.

This is all wrong; yet such mistakes do occur, even with practical men. The correct methods for position of risers on similar stairs have already been given. But here an error has been committed, which must be covered by producing a wreath to stand over it; so that no imperfection shall appear in either rail or stairs. This will not be difficult when we have a system which applies with certainty to every situation, be it right or wrong.

Fig. 2. Line A B shows height of riser, and A C the step. Let under-side of level rail be half a riser above landing. Set off thickness of rail from both rake and level, and draw lines intersecting at E. Square down from E, cutting at D. Let D L equal D A. Tangents are now in position for lower part of wreath. The line D L falls level, and A D stands on pitch V E. Square over V N. This gives N E for height.

Fig. 3 shows construction of mould. Let A, D, L equal tangents above. Draw L H extended and parallel with A D. Make H T the height, equal that of N E above. Join A T extended. This line being both pitch and major axis gives plain directions to strike mould, as hown.

This piece of wreath forms its own casing, similar to that starting from a newel. Stuff for level piece should be a little thicker than that of the rail, say half an inch. This gives the opportunity of increasing the curve across joint on upper and lower side, and adds much to appearance of wreath.

It is understood, however, that the additional stuff, being more than the thickness of rail, throws level that much higher. That being so, lower the height N E half an inch.

Referring to Fig. 1, it is seen that riser-landing stands in the cylinder. Height of level rail is the same as that on right. The letter E shows intersection made by pitch and level. Perpendicular E D gives H D, and D L for tangents. Letters K V show height of wreath, and K E the ordinate.

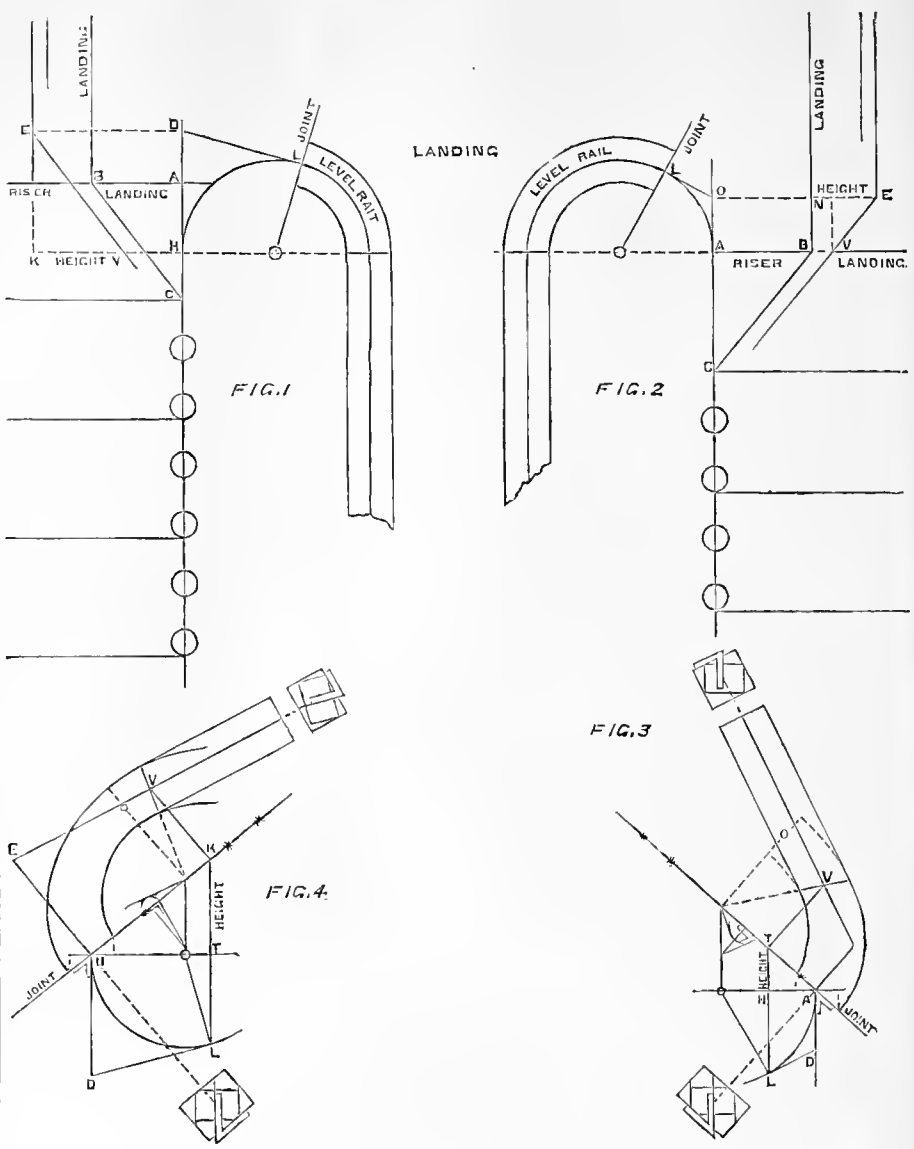
Fig. 4. Let H, D, L equal tangents above. Draw L T extended and parallel with D H. Let T K, the height, equal that of K V above. Join H K extended. Next, square over K and H. Let K V equal T L, and H E equal H D. Join E V extended. This line, to be correct, must equal that of V E above.

To find width of mould on wide end,

Set off half width of rail on each side of H. Then draw parallel with H D to cut pitch. Now find points to insert pins and strike the mould. Observe that the tangents at Fig. 1 throw the joint past centre. This gives to the lower piece of wreath sufficient casing. Then, the level part connecting with it remains the same thickness as that of straight rail.

A class for the study of land surveying is about to be formed by the members of the Architectural Association.

* This series of articles is a reproduction of Robert Riddell's work on the subject, published in Philadelphia, and by Trübner and Co., London.



NEW ELEMENTS OF HAND-RAILING.—PLATE XXIV.

CHAPEL IN TRANSEPT OF MUNSTERMAIFELD CHURCH, RHENISH PRUSSIA.

The church of Munstermaifeld is composed of many parts, built at different times in the middle ages. In plan it is similar to most of the churches on the borders of the Rhine. The front dates from the epoch of the Carloviogian dynasty, while there is reason to believe that the basement existed in Roman times. The three towers are of much more recent date, having been added so late as the fifteenth century. The dates of the choir, nave, transept, and two chapels are from 1255 to 1260. Our illustration represents the interior of one of the chapels. The style is Transitional, and the beauty of much of the detail well worthy of notice. The material is a very soft stone called "tuff," frequently found in the Rhine Provinces. Paul Tornow.

STREATHAM HILL CONGREGATIONAL CHURCH.

This church, a view of which is given in our illustrations this week, is in course of erection from the designs of Mr. E. C. Robins, of 16, Southampton-street, Strand. It occupies the site of the quasi-Classical building known as Union Chapel, which was erected in 1829. The church is designed in the Early French Mediæval style, with lofty nave and aisles, but no clerestory. An open porch with coupled Devonshire marble columns and carved caps is situated between the west gallery staircase and the tower and spire. There are transepts at both the eastern and western ends of the aisles. The organ gallery is behind the pulpit and platform, and the deacons' vestry is beneath it, on one side of which is the minister's vestry, and on the other the eastern gallery stairs. Upwards of 800 persons are to be accommodated. The nave columns are 14in. diameter, and alternately of red Mansfield and Blue Pennant stone, with Portland carved caps and moulded bases. The cast-iron zones receive the ends of the gallery trusses which support the galleries on the north, west, and southern sides of the building.

The interior has an open roof, and walls faced with white gault bricks, relieved by red gault bricks in patterns and Bath stonework. An elaborate Caen stone screen and pulpit, supported on marble columns, forms the eastern termination of the raised platform and tesselated pavement. The windows are all filled with tinted glass in patterns, and a painted wheel window will be fixed in the east gable wall of organ gallery.

The exterior of the building is faced with Kentish rag with Bath stone dressings. The bands in the spire are of red Mansfield and Blue Pennant stone. Mr. Higgs is the contractor.

GLASGOW.

At a meeting of the Town Council, held last week, a Mr. Kibble offered as a gift to the City, upon certain conditions, a conservatory valued at £15,000. At the same meeting a proposal to form a swimming and skating-pond on the Green was rejected by a majority.—A Mr. Barclay, who dates his circular from the University, advertises that he "is at present forming a class for the study of architecture as a fine art, to be held in the Corporation Galleries."—It is expected that the Albert Bridge will be opened this month—probably on the marriage day of the Princess Louise.

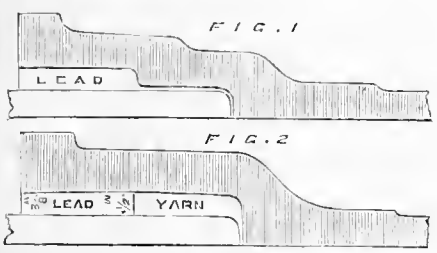
WATER MAINS.

SOME time ago we gave a series of articles on the supply of water to towns, but the practical work of pipe-laying was not touched upon. The following remarks may be taken as supplementary to that series :—

Pipes for the conveyance of water underground are usually made of iron, cast from the furnace, in lengths of 9ft., but large main pipes are sometimes made 12ft. long. The external diameter of the pipe having been determined, the pattern from which it is to be cast is placed in a dry sand mould, and on its being withdrawn a core is adjusted accurately through the centre of the mould, of such a diameter as will allow of the required thickness of metal being cast around it. When pipes are cast horizontally, or more or less slanting, the core by its weight sags or bends downwards in the middle, causing a greater thickness of metal on the upper side and a less thickness on the lower side than had been calculated upon. Therefore, it is preferred to cast the pipes vertically, by which means, with proper care, a very uniform thickness of metal may be generally obtained. For this purpose a special pit is required, of considerable diameter and depth, and it is not at every iron-foundry that it is at all convenient



to construct such a pit, and those foundries possessing them have much advantage in competing for large pipe contracts. Branches, bends, and other irregular pipes are cast in boxes, horizontally, and to guard against the difficulty of keeping the metal of uniform thickness, it is made greater than that of the straight pipes to which the irregular pipes belong.

WEIGHT.

The thickness of which pipes are usually cast, and, therefore, their weight, varies with the positon in which they have to be laid, embracing considerations of the head of water under which they are to be placed, and the external pressure to which they may be liable, as well as of whether they will be liable to sudden checks in the flow of water in the larger mains, but an average strength may be stated to be as follows:—

Diameter.	Thickness.	Weight.		
ins.	ins.	cwt.	qrs.	lbs.
3	3/8	1	0	14
4	7/16	1	2	7
5	1/2	2	0	21
6	9/16	2	3	14
7	9/16 & 1/32	3	2	7
8	5/8	4	1	0
9	5/8	4	3	21
10	5/8 & 1/32	5	2	14
12	11/16	7	1	0
14	3/4	8	3	7
16	13/16	10	2	7
18	13/16 & 1/32	12	3	0
20	7/8	14	3	0
24	1	20	0	0
30	1 1/4	28	2	0
36	1 1/4	38	2	0

These thicknesses are not in all cases exactly those which give the weights stated, but are given to the nearest 32nd part of an inch; and in practice it is better to specify the exact weights required rather than the thickness, the core being turned down to the size required to give those weights exactly, or as near as practicable, in the casting.

COST OF A LINE OF PIPES.

The price of pipes varies with the state of the iron-market, and so affects the ultimate cost when laid down; but an average cost per yard of a line of pipes laid complete, with lead joints, may be taken to be as follows :—

Diameter.	Cost per yd.		Diameter.	Cost per yard.	
ins.	s.	d.	ins.	s.	d.
3	4	3	12	21	6
4	5	6	14	29	0
5	7	0	16	35	0
6	9	0	18	41	0
7	11	0	20	48	0
8	13	6	24	58	0
9	16	6	30	78	0
10	19	0	36	105	0

Besides the cost of the pipes themselves as castings, there are some preliminary expenses to be incurred before the pipes can be laid. A coating of something that will prevent the oxidation of the iron is necessary, at least, in the inside of the pipes, and it is all the better if they be coated both inside and out. When only the inside is coated, lime is sometimes used in the form of a wash; quick-lime being mixed with water to the consistence of cream, and applied with a brush; but another method, and that now more generally adopted, is one invented by Dr. Angus Smith, and consists of a coating of the pitch of coal-tar, which is melted and heated to a high degree, and the pipes are dipped into it whilst they are still hot, thus coating them both inside and out. It has been found that when this process has been well performed the coating has continued perfect for many years; and it has the beneficial effect of reducing the friction of the water passing the pipes by offering a smoother surface to its action than the crude iron presents. This process adds about 5s. per ton to the cost of the pipes. Then there is the carriage to the wharf or railway-station near which the pipes are to be laid, and the haulage from thence to the trench.

TRENCH WORK.

The pipes having been laid alongside, the trench is excavated to such width as will give room for the excavators to work in, and to a width sufficient to allow of the excavated material, when it shall have been refilled into the trench, being well rammed under the sides of the pipes, which cannot be done properly without from 6in. to 8in. of room on each side of the pipe.

Refilling a pipe trench, like any other filling or embankment, is to be done in regular layers, not too thick to allow of their being well rammed and consolidated, for which purpose they should not exceed a foot in thickness; indeed, to prevent further settlement, 6in. is as much as should be allowed. The width of the trench at the bottom ought to be so much wider than the external diameter of the pipes as will allow the punners (to use a navvy's word, which means pounders) to be used freely to ram down the earth solidly underneath the sides of the pipe. Unfilled spaces left under the sides of the pipe will become self-filled in course of time, by the solvent powers of the air they contain, causing a gradual settlement, which may be years before it ceases; and in roads or other frequented places this sinking, being unperceived until the crust suddenly gives way, becomes very dangerous.

But besides this general width an extra width is required at the joints, to allow the pipelayers room to turn and work in, and this should be at least 9in. wider on each side than the width of the trench. The length of the joint-hole, in the direction of the line of pipe, should not be less than 2ft. for any size of pipe, and for large pipes, where double-handed hammers have to be used, 3ft. The widths here given are those suitable for good, firm, and dry ground, and for the smaller sizes of pipes where no timbering is required; but where the trench is of considerable depth an additional width of 6in. is required for the thickness of the walings, 3in. on each side; and where the ground is so bad as to require poling boards behind the walings, a further width of 3in. is required for them, 1½in. on each side; and further still, where the ground is of such a nature that boards cannot be driven, but that close-planking is required, then instead of 3in. for poling boards, 6in. must be allowed for the thickness of the planks or deals. Moreover, in any ground, although there would seem to be no difficulty in doing it, the sides of the trench cannot, in practice, be cut down perpendicularly; so that even when no timbering is required there needs to added to the bottom widths 6in., at least, for the top width.

The depth of a pipe trench is governed by the consideration of how far below the surface frost will penetrate, and, in the case of large pipes, how deep they must be laid to be beyond the jarring effects of traffic over them, which has a tendency to cause leakage at the joints by starting the lead filling, which is more easily effected when to the steady pressure of water in the pipes is added the jarring here alluded to.

There is another reason for laying large pipes deeper than small ones. It is known that a cast-iron pipe of large size will not bear much external pressure; and when we consider the enormous weights—say large boilers or traction engines, which may pass over a line of pipes—it is well to take the precaution to prevent the pipes being subject to these pressures. The following are the least depths for pipe trenches, to which must be added 9ins. each joint hole. Greater depths than these will occur in places along most lines of pipes, where, for instance, a rise in the ground is to be cut through to avoid an air lock, or where a culvert or pipe has to be passed under; but all these are to be considered special depths, and in all cases extra to the depths given. The widths and depths are as follow, the width being that at the bottom, and the depth the minimum depth, exclusive of joint-holes :—

Diameter of Pipe.	Width of Trench.		Depth of Trench.	
ins.	ft.	ins.	ft.	ins.
3	1	3	2	3
4	1	4	2	4
5	1	5	2	5
6	1	6	2	6
7	1	7	2	7
8	1	9	2	8
9	1	10	2	9
10	2	0	2	10
12	2	3	3	2
15	2	6	3	6
18	2	9	3	11
20	2	10	4	2
21	3	0	4	4
24	3	3	4	9
27	3	6	5	2
30	3	9	5	6

The expenses in laying pipes consist of, besides those of the trench, those of lead, yarn, coals, tools, getting the pipes into the trench, jointing, caulking, running, and setting up.

As to the kind of joint, the old lead joint maintains its position of general usefulness amongst several other kinds that have been proposed, one only of which has come into use—viz., the turned and bored joint; but this is only suitable for straight lengths, and where the ground is not perfectly hard and unyielding it is too rigid. Iron cement and wood have both been proposed but never used; gutta-percha also has been proposed, but the most generally useful joint is undoubtedly the lead joint.

JOINTS.

A lead joint is made by first caulking it with white spun yarn to a depth of from 2in. to 2½in. in depth, according to the size of the pipe, and the outer space, being from 2in. to 2½in. in depth and from ⅜in. to ½in. in width, is run with lead, a band of well-tempered clay being first put round the front of the joint, working it upwards from the bottom

and leaving a hollow space at the top, into which the melted lead is poured, which runs round and fills the joints at once, if the ladles are large enough or brought up in sufficiently quick succession to completely fill the joint at one running, which should always be done. After the clay-band has been removed and laid aside to be worked up again, the excressences of lead are cut off with chisels, and whatever lead may remain projecting outside the end of the socket is set up all round, with properly cranked steel tools, so that they may be held in one hand whilst they are struck by short-handled square-faced hammers with the other; or else, where the pipes are large and the work heavy, the setting-np tools are held in hazle set-rods by one man, while another strikes them with double-handed hammers. The caulkers and the setters-up are usually separate sets of men where the work is of magnitude, the one set preparing the way for the other; but in laying smaller pipes the same set of pipe-layers do both. The dampness of the clay-band and the moisture on the pipes give off a vapour when the hot lead comes in contact with them, which blows out the lead in spray, and is dangerous to the workmen if the precaution be not taken to put into the hollow into which the lead is poured a small quantity of resin.

SOCKETS.

The hard setting up of the lead has a tendency to split the socket of the pipe, and its outer edge is therefore thickened very much beyond what its strength would otherwise require to be. It is usually about twice the thickness of the body of the pipe, while the body of the socket is half as thick again as the body of the pipe. There are various ways of forming the socket of a pipe. Sockets of the shape shown in fig. 1 have been used to save yarn and to ensure the spigot end of the pipe being brought up to the level of the body of the adjoining one; but the risk, unavoidable with large numbers of pipes, of some of the ends being not truly cylindrical, renders this method undesirable; for without the greatest care and patience of the pipe-layers turning the pipe about when they find it will not go "home," pipes are liable to remain only half-way home, and so bad joints are made; while, by employing a couple of short wedges, one on each side of the pipe underneath, to bring it up to its proper level, the annular space for yarn and lead can be easily equalized, and a good joint made with plain sockets.

As to the form of the lead space, it is better to make it as shown in fig. 2, so that the lead assumes a wedge shape on the side on which the pressure comes upon it, tending to prevent its being blown out.

Sometimes a bead has been cast round the end outside the pipe, to prevent the yarn being driven into the interior of the pipe, but in severe frosts pipes are contracted, and the bead draws out the lead, which is not returned into the socket when the pipes expand again, but is left protruding, so that pipes are now generally made with plain ends. Similarly, a band, or a couple of them, used to be cast round the body of the pipe, but there is no necessity for them.

In laying large pipes, they must necessarily be laid singly, while two small pipes of 3in. or 4in. diameter may be jointed outside of the trench, and laid together. For large pipes, special machinery is required for laying them. The common three-legs do well enough for pipes up to about 18in. diameter, but for those of 24in., 30in., 36in., and 40in., wheeled carriages are better. A convenient form is one with two wheels, with a bowed axle, from which the pipe is slung by blocks and chains. The pipe is rolled up to the trench as near as may be to where it is wanted, and the pipe-carriage picks it up and carries it to its place and lowers it into the trench. Cross timbers and runners of half-balks are required for this work, and to prevent accidents from their breakage, the soundest Baltic fir timber should be selected. Oak or other hard wood is too heavy to move about, and American pine gives too little warning of its being overloaded before it breaks, but good Memel or Dantzic fir combines the qualities most required.

To get the pipes from the wharf or depot to the trench is sometimes not an easy thing to be done when they are heavy. Hauling-carriages are sometimes made to run on four wheels, but a very good form of carriage is one with two broad wheels with a bowed axle, from which the pipe is slung. For small pipes a low four-wheeled truck is used, on to and from which the pipes are rolled; but for pipes of large size it is usual to sling them underneath. The ordinary two-wheeled cart is very unhandy for this kind of work, even for the small pipes.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

THE twenty first lecture of this course was delivered by Dr. Zerffi in the Lecture Theatre of the Kensington Museum on Tuesday afternoon last. The lecturer said that in summing up the contents of the preceding twenty lectures it would be found that the statuary of the ancients might be divided into three great groups, viz., the Symbolic, the Idealistic, and the Naturalistic. Egypt was the representative of symbolism, Greece of idealism, and Rome of naturalism. In these three divisions many phases and amalgamations of other styles had been and would be traced. The styles represented the stages of transition from the first attempts in art to the most glorious productions of architecture and sculpture—from the first scanty lines in ornamentation to the well-regulated symmetrically-arranged decorations of Greek works. The whole surface of the globe had nowhere shown a decline in art; on the contrary, from the pottery of prehistoric times and the rough wooden dolls of Egypt, Assyria, India, or Greece, to the Zeus of Phidias, mankind had slowly but surely drawn nearer to perfection. There could be no doubt that this progress did not take place everywhere simultaneously, but passed like a vivifyiog shower over districts, producing various fruits according to the quality of the soil. In science actual knowledge was the sum total of all the ideas, discoveries, and theories which had preceded our times, and this was the case with art in general—with ornamental art especially. The general motives and forms were given, and all depended upon the right use and variation of that which had been handed down to us by former generations. The three groups, symbolic, ideal, and natural, still ruled supreme, and only a right understanding of the sphere of each would enable us to progress in art. The Aryans had shown their intellectual superiority on the Ganges as metaphysicians and constructors of rock-hewn temples. They had built palaces and towers round Babylon and Nineveh; had, as Persians, made conquests on the Euphrates and Tigris; and had produced marvellous works of art in Attica and the Peleponessus, and at Argos, Rhodos, Korinthum, Syrakos. The same Aryan spirit might be traced on the shores of the Nile, founding the most powerful hierarchy, and astonishing the world with gigantic architectural productions. We had found the same element on the other side of the Atlantic, having discovered traces of analogous works of art on the shores of the Orinoco, Mississippi, and Lake Titicaca. Wherever a free intercourse with Nature had taken place, a symmetrical appreciation and correct reproduction of forms had been the result. On the other hand, we should find that wherever the productions of Nature had been looked upon as being those of an evil spirit, this had not been the case. The more man occupied himself with the contemplation of Nature, the more he realised the peculiar charm of the blended beauties of sea and land, and of human beings endowed with the divine spark of intellect, and with bodily grace; and the more he advanced in artistic power, plants and flowers, trees and waves, became animated, and Nature spoke to the imagination the intelligible language of beauty. Their reproductions were but echoes—transcriptions of the whisperings of Nature. We could trace in art many deviations from the path of beauty, but we should find that through all the vicissitudes of its historical progress the productions of our great Greek masters were never altogether forgotten or lost. In reference to the works of the Etruscans, Dr. Zerffi observed that the origin of this people had been traced to the general group of the Aryans. The first settlers in Etruria, the Pelasgians, had built the town of Tarquinii, which for a long period remained the chief town of the Etruscan confederation, and had always been the centre of Greek culture. Having settled on the western slopes of the Apennines, this nation had, at an early period, to struggle against the powerful influences of Nature, and was driven to industry and enterprise. The people, the lecturer continued, had had to gain their soil by force. In spring they were compelled to stop the inundations caused by overflowing rivers, and in summer to provide water for the parched valleys. They soon became masters of the arts of constructing aqueducts and irrigating land. They were superstitious, but this was not to be wondered at, as the most extraordinary petrifactions everywhere abounded. Near Contesi the bones of a whale had been found, and the Valley of the Arno resembled a burial place for elephants. The bones of the mastodon, the rhinoceros, and the hippopotamus were scattered all over old Etruria, and were used to fence in the fields. Those of bears, wolves, hyænas, panthers, &c., were, however, in such abundance that the peasants even at the present day believe they grew like plants, and were sown by invisible spirits. The aspect of Nature and the remains of an antediluvian world had given the Etruscan priesthood an irresistible sway over the minds of the people. The Etruscans, unlike the Greeks, in whom the sense of the beautiful was keen and intense, had directed their minds to gloomy contemplations or to practical purposes. To defend their towns they constructed walls, and to protect themselves from imaginary monsters they built excellent houses. Their temples differed in some details from those of the Greeks. The cella had generally been square, and sometimes more than one had been constructed in the postica. The antica had been filled with columns. The style was Doric, but the Etruscans never attained that earnest majestic simplicity which brought this order to such perfection in Greece. The columns had bases, were more slender, and stood further apart, supporting a wooden roof with clumsily protruding beams and unwieldy cornice and high pediment. Some cinerary chests showed Greek forms, but were of coarse workmanship. To tombs and burial places the Etruscans devoted great care. These might be classified under five headings—(1) Subterranean tombs, hewn into the tufa with steps leading underground; they were generally provided with a vestibulum consisting of several chambers, sometimes supported by columns. The ceiling was either horizontal or pointed (in imitation of a wooden roof). Tombs of this class were to be found at Volci, Clusium, and Volaterræ. (2) Subterranean tombs with tumuli above them; they were generally single graves. The corpses were placed on stone beds, to be found at Tarquinii. (3) Burial chambers (cocumella) with artificial hills above them, provided inside with a tower-like construction, to be found near Volci, Tarquinii, and Viterbo. (4) Chambers vertically hewn into rocks, with a simple or ornamental entrance, to be found near Tuscania. (5) Similar rock-hewn chambers with façades screening the entrance; these façades were either in the form of doors (as in Aria) or of Doric fronts (as at Orchia). The tombs were all more or less ornamented. In all Etruscan productions the predominating element was the want of idealism, as they possessed only a sober spirit of practical execution. Many of their sculptures connected this people directly with India and Egypt. The importance of their art, from an historical point of view, was derived from the obstinacy with which they had held to the old traditional forms and types of the East at a time when Greece could already boast a perfect art. This was clearly proved by their tombs, the reliefs of which were full of lively scenes, reminding us of Assyrian and Babylonish sculptures. Having described these reliefs in detail, the lecturer went on to say that the Etruscans had at a very early period excelled in pottery and metal works. Chiselling and founding were well known to them, and a vast number of chests, candelabra, mirrors, and other objects testified to their ability in working gold, silver, and bronze. About 660B .c. Euchier, Diopos, Eugrammos, and Demaratos were driven into Italy from Korinthum, and had taught the Etruscans a higher kind of artistic feeling. From that time these people had

especially excelled in terra-cotta works, as was shown by the specimens of vases, amphoræ, statuettes, and bronze works. They were very fond of bodily ornamentation, and this was the case at the present day with the peasants. To wear a ring was considered essential by an Etruscan, and this accounted for the fact that the art of cutting stone (*glyptics*) was so much cultivated amongst them. In illustration of those remarks, Dr. Zerffi drew attention to a collection of specimens of jewellery, &c., from the Museum, and said that Etruscan works of art might be divided into five classes, which were (1) the original Tuscania (as they were called by Strabo), or Etruscan products, which were heavy in form and details. The dresses were stiff, and a peculiar characteristic of the figures was that they were without beards. Of this class we had many bronze works, very few sculptures in stone, some gems, and some very ancient wall-paintings,. (2) Imitations of Oriental (especially Egyptian and Babylonish) forms. Tapestry was much used for floor and wall decorations. These productions were good as imitations, but were wanting in originality. (3) Caricatures, which were always to be found at times when nations would not look upon art from a higher point of view. Taste degenerated, and the quaint was preferred to the harmoniously simple. The imagination once driven in this direction exerted itself to excel in grotesque compositions; and as these productions could not be brought under the rules of strict beauty, artists found them easier, and, therefore, more delightful. (4) Works in the best Greek style in bronze only, such as frames and handles of mirrors. The modern *articles de Paris* had their prototypes in the "articles of Etruria." Whenever the higher spirit of art was neglected, the dynamic force created highly-meritorious works, but on a far smaller scale. (5) Mechanical products. With reference to these, the lecturer observed that art, looked upon as an outgrowth of bare necessity, could not flourish. The utilitarian incubus expelled all higher ideas and aspirations from the brain of the artist, and only where the two elements—the utilitarian and the artistic—were combined could real works of art be expected.

In his next lecture Dr. Zerffi will take up the subject of Roman art.

BUILDING SURVEYORS AND CONTRACTS.

THE President of the Royal Institute of the Architects of Ireland, in his inaugural address, among other topics, touched upon the duties of building surveyors with regard to quantities and measurements. Certain views expressed by the President led to the subject being taken up by Mr. J. Mc. D. Bermingham, associate, who, on the 16th ult., read a paper of which the following is an abstract.

After referring to the way in which the practice of preparing detailed bills of quantities for nearly all building works to be contracted for has increased of late years in Ireland, Mr. Bermingham proceeded to show that the issuing of such quantities was desirable, on the grounds that fair remuneration for fair work is the guiding principle to produce harmonious action between architect, builder, and client, and by having a carefully prepared bill of quantities a great obstacle is overcome, carrying with it, as it should, the belief that the actual work to be executed is therein represented, beside presenting an array of prices likely to meet any emergency in the event of alterations to the contract. Having spoken of the advantage conferred on the architect by having the assistance of a surveyor, inasmuch as he was relieved somewhat of the responsibility resting upon him, the author next considered the question, whether the absorbing of the duties of the quantity surveyor into those of the architect would be judicious? He did not believe it would, for it would be a combination in which, on the one side, the ideal and the artistic should largely predominate in the mind, while on the other, it is the dull monotony of calculations, the tedious unravelling of problems which necessitate patience and perseverance. To be skilled in architecture requires all the study and practice which a student can give, without more than incidentally acquiring an insight into the systematic principles involved in ascertaining the work to be executed, and in dealing with alterations arising in course of execution; while to be skilled as a surveyor, also requires a great amount of study, besides a much more intimate knowledge of the working of a builder's business, both as regards the various means of best and most economically providing all materials, and of disposing of the same in the structure. The taste developed in designing is rather antagonistic to that developed by the incessant routine of calculations. As regarded the idea of the architect having a deputy to perform the duties of a quantity-taker, Mr. Bermingham had grave doubts as to whether it would be found to work well. Of course it was quite feasible to have the quantities issued in that way, but he concluded that the builders would urge the attachment of the quantities to the contract, and in that case would such a deputy be found equal in discussion on all questions arising to the independent surveyor, with his great and varied range of experience? He (Mr. Bermingham) thought not, and therefore he dissented from the President's recommendation of combining the duties of the quantity-surveyor with that of the architect, except so far as it suggested the employment of a separate party. Though the two branches were combined in practice in many parts of England, that fact afforded no proof that that plan was better than the separate system adopted in London, from which, as being the scene of the largest experience, a strong precedent might be taken. Referring to the custom of Scotch architects, Mr. Bermingham said that from a letter he had recently seen it appeared that in Glasgow the quantities are used principally as a schedule of prices, and that the whole work is measured at periods during the course of erection, as may be most convenient, the contractor being paid, according to the schedule, for all works over that returned in original quantities, and having deducted all under amount therein represented. The only way he can absolutely lose, therefore, is by undertaking work at too low a price. The payment for measurement of executed work is defrayed, half by employer and half by contractor. Though this principle possessed many good points, and recognised the honesty of paying for work done if same had not been included in the data from which the lump sum was arrived at, and *vice versa*, it would largely increase a surveyor's duties, and the author did not think this plan was the most desirable. Would it not be time enough, he asked, to incur expense of this kind if the contract was departed from, in which case the amount of departure could be ascertained without the necessity of a total measurement? There evidently existed a strong confidence in thus mutually abiding by the impartial judgment of an independent surveyor as to the quantity and value of the works executed, and from it the author inferred that the aim of the proposal in the address could be obtained by a simpler but probably quite as effectual a process.

Mr. Bermingham next proceeded to consider what steps are necessary and practicable to operate successfully in procuring a firm basis on which contracts can be entered into and completed with an honest impartiality, and to the satisfaction of all concerned, and especially with a view of improving the confessedly unhealthy position and relations of the independent building surveyor. The latter, in many cases, is looked on as an unwelcome intrusion; and though much may be said against him *under existing arrangements*, he is, on the other hand, made to bear burdens not properly his own. This is to be attributed to the most unpleasant position in which he is now placed. He is not supported by his natural ally, the architect, and is barely recognised except as the servant of the builder. Why is this? Is it because in the main he is employed by the contractor, and, in the honest protection of interests entrusted to him falls foul of the architect? Is it because in points of dispute he sometimes is enabled to prove that certain claims must be allowed—claims which increase the expenditure to an unlooked-for amount? Or is it because there is an impression that in preparing the original bills of quantities, the tendency, unavoidable though it may be, exists of measuring same "full," thereby increasing the amount of tenders to the prejudice of the client, and widening the difference between same and the approximate estimate of the proposed works? Among these questions may be found some idea of the reasons that have brought about this state of things; and with a proposal before you of re-uniting that branch to the others of the profession, it seems rather strange, that within the lapse of a comparatively short time such a feeling of estrangement should be engendered by the separate practice. Does there exist now a greater proportion of disputes than formerly by which this feeling would have been encouraged? Now though Mr. Bermingham did not desire to exculpate surveyors (for some of them were, in his opinion, largely to blame in having brought about their present position), he could not help expressing his belief that architects were not without some responsibility in such being the case. Moving in the higher branches of the profession, with influence of no small degree in regulating all matters in connection therewith, and as arbitrators between the public and the contractor, it was their place to inspire confidence in the class risen up to discharge the duties laid aside by themselves, and to have used their influence to prevent classes creeping in which have eventually created the present unhealthiness. The surveyor is of course, in common with the rest of the world, liable to err; but this is not to be wondered at when you think of the great division of his labour, the numberless items which, while essential to the carrying out of the works, are arrived at by continued strain on the memory—by, in fact, raising the edifice in his mind; the systematic care required in transferring to paper all the items occurring in so doing; remembering also, that by far the greater liability accrues to him from forgetting something altogether, or in part, than from returning same too "full." Considering these matters, there must be an instinctive inclination towards returning each item a little "full" in order to protect from loss the people with whose interests he is entrusted, as he finds, on entering the pursuit of his business, that he has a larger share of support from the building community than from the public or the architects who represent them. Again, where work is advertised, every class of builder may come together, as also it may be the case in limited competitions, where the greatest strictness is not pursued. So long, therefore, as architects stand aloof, and that the present system exists, the tendency with the surveyor must be to strain the mind's view of the impartial and just. With the adjusting of final accounts the surveyor becomes much associated, and unless when employed by and between the parties concerned, he should not be looked as an arbitrator, either in theory or practice. In rare cases this does occur, and the result goes to prove that the mutual confidence has not been misplaced, that an impartial and fair view is striven to be taken of the meaning and construction of the contract, and the various documents that form part thereof. On the other hand, when the surveyor is employed either to measure "extras" and "omissions," furnishing the contractor's account, or to check same on the part of the client, when submitted, he at once loses any claim to the position of an arbitrator, except so far as consists in watching the interests of his client.

As before remarked, architects are not without some responsibility for the very unwholesome state of things which undeniably exists. Is it not an unpleasant fact that the public regard an acquaintance with stone, brick, and mortar as a species of speculation in which all their calculations are only ideal? Is it not characteristic of some architects that they aim at obtaining the greatest accommodation and effect for the sum proposed to be expended, and does it not often occur in that endeavour the mark is over-reached? With this result, that when the tenders are received, and the works proceed, dissatisfaction ensues, the client being put to a greater outlay than he desired. Another not unusual cause arises in the plans and specification not being clearly defined. The surveyor is, therefore, obliged, in many cases, to decide for himself between different views, and, as a necessity, has to adopt that which will prevent his client from subsequent loss; while, had sufficient details of work and specification been furnished, he could better perform his duty, while the tenders would be reduced by a perceptible percentage. Another cause, and one prolific of unpleasant consequences, occurs in the matter of throwing the onus on the contractor, and binding him up with all kinds of conditions and clauses—no doubt justifiable, as intended against those who cannot act uprightly, but certainly not necessary if a proper and judicious selection be made of men of respectability and character. He is compelled to give security for the performance of his portion of the contract, while the party with whom he makes same, though possibly not a whit more honest or safe, gives none for the performance of his, viz.—*the payment*, and this may account for the general preference for executing contracts for and with public bodies in contradistinction to private individuals. In fact, so numerous are such contingent clauses, that in few cases can a contract be entered into where the

party who makes same has not some game of chance which may end profitably or the reverse. This practice, Mr. Bermingham went on to show, is neither conducive to the healthy development of business, nor founded on a spirit of equity. It is productive of disappointment, disagreement, and wrangling, until nothing outside the strict letter of the contract will be thought of, and the settlement finally becomes one of trouble and perhaps litigation. Why not, he asked, have contracts founded on a firm and strictly definite basis? Why not the preliminary difficulties disposed of by the surveyor, as far as possible, at the cost of the proper party—the employer; and such things as extra depth of foundations, increased expenditure in protecting other properties, the connecting staunchly of adjoining buildings, and other such considerations, be kept separate, to be paid for over and above the contract made, according to the actual outlay or value?

Referring to the questions of the quantity-surveyor's responsibility and charges, the author said that to what extent the surveyor was responsible was a point most unsettled even in London practice or as sanctioned by law, and with all the faults of the existing system it is difficult to consider how he could honestly discharge his duties and feel the responsibility resting upon him. Why should either the builder or surveyor be asked to pay for work which, though omitted from the bill of quantities, from which the total value is derived, the employer is directly receiving the equivalent for? Why should he not honestly pay for it?

On the subject of charges, little can be said. Among surveyors, as among architects and every other class of men, you will find some who will undermine any regulated scale, and others, not content with it, will adopt one more remunerative, and what they consider themselves entitled to for the services they render. You cannot control this, but you can render a permanent service by giving forth to the profession—under the most important professional body constituted in this country—a scale of fees ascertained from the practices and customs extant.

In conclusion, Mr. Bermingham made the following suggestions:

Let every architect employ his own surveyor in all cases, and let him be paid either by his clients directly, or through the architect.

Let fair, equitable, and definite contracts be formed, and the contractor be paid separately for all contingent works outside same.

Let the contractor have the option, before signing the contract, of assuming the whole responsibility of the surveyor's work, no errors in same to be of any avail, or claim against any party concerned; or let him sign it, having the bill of quantities forming part of contract to be used as a schedule of prices, and in case errors occur, the amount of same to be either added to or deducted from the contract amount when they exceeded a certain percentage of variation.

Let sufficient details be given beforehand by the architect. Let him examine the plans and specification when they pass from the surveyor's hands, carefully noted and revised by him.

Let all variations from the contract be arrived at by the surveyor independently between party and party, unless in such extensive works where two surveyors would be advisable.

Let a spirit of mutual confidence be inspired among all concerned by having the contracts on a fair, equitable basis for both parties, by careful selection of respectable and upright contractors, and by reposing confidence in surveyors who seek to impartially administer the trust placed in their hands.

Let every question of importance be decided by the architect as an independent arbitrator, when worked out and referred to him by the surveyor; and in any case where the parties concerned will not abide by the decision, let a clause in specification refer same to the friendly arbitration of members of the Institute chosen by each, a proceeding found to work so peacefully and amicably with merchants and their Chambers of Commerce, thereby avoiding all law.

Lastly, and above all, let there be unity of feeling and action in the general endeavour to eradicate the evils existing. Let some scheme be fostered that will carry us out of this difficulty, perplexity, and trouble into a future where the man who wishes to build a mansion can do so with the same feeling of confidence, security, and pleasure as he would the furniture to decorate it.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE following correspondence refers to the subject of our first leading article this week:—

21, Upper Bedford-place, Russell-square,

Dear Sir, 9th March, 1871.

The discussion which took place at the meeting of Members on Monday last was of such a nature, as to oblige me to write to the President, resigning my office of Honorary Secretary. I think it but respectful to send you a copy of my letter, and to express my liveliest gratitude to yourself and the other Members of the Institute for the kind consideration I have ever received at your and their hands.

Believe me, my dear Sir,
Most faithfully yours,
Thos. L. Donaldson.

Copy.

Mr. President, 8th March, 1871.

The proposition, which you have formally submitted to the Royal Institute of British Architects, that the present Assistant paid Secretary should be raised to the office of Chief (not Honorary) Secretary and Member of the Council, and should have the sole control and management, under the Council, of the affairs of the Institute, so that, in effect also, the other, the Honorary Secretary, would be subordinate to him, is an arrangement which I think will be very prejudicial to the official department of the Institute, and consequently to its best interests.

This leaves no other step for me to take, or any other Member of the Profession who has any respect for himself as Honorary Secretary, than to decline to be put in such humiliating subordination.

I therefore place my resignation unreservedly in your hands, and I must request that my name be withdrawn from the list of Fellows.

I desire not for one moment to stand between the wishes of the Members and what *they* may consider best for the interests of the Body. I beg them to consider this as only one more last instance, painful as it must be to me, of the affection and devotion I feel for an Institution in whose formation I was an humble instrument, and to whose success I have devoted the most earnest services and unswerving duty during six and thirty years. I have done so without any other object or desire of reward than the consciousness of having served the Profession.

Believe me, Mr. President,
Very faithfully yours,
Thos. L. Donaldson.

Thos. H. Wyatt, Esq. President, R.I.B.A.

ARTISANS', LABOURERS', AND GENERAL DWELLINGS COMPANY.

THE fourth annual meeting and soirée of this company was held on Wednesday evening last at Radley's Hotel, Bridge-street, Blackfriars, the Earl of Shaftesbury in the chair. Mr. J. Baxter Langley, the Chairman of the Board of Directors, before proceeding to make a statement of the affairs of the company, announced that letters had been received from Lord Derby, Dean Stanley, Mr. John Stuart Mill, and other distinguished noblemen and gentlemen, expressing regret at being unable to attend. From the report it appears that at the close of last year the share capital amounted to £3,014; it is now increased to £6,000, and the uncalled capital has risen from £15,000 to £26,000. There are now 1,250 shareholders, being an increase of 290 during the year. Notwithstanding that the past year has been one of great depression, nevertheless the directors are enabled to pay interest of 5 per cent. on deposits and 6 per cent. dividend on share capital, leaving a balance of £401 7s. 6d. to carry forward to a reserve fund. The company has just completed the erection of a large number of improved workmen's dwellings, with lecture-hall and school-rooms. The greatest attention has been paid to ventilation and all sanitary arrangements, and dry ash closets (the patent of which the company has purchased) are used in preference to water-closets. The directors are preparing plans for the erection of their model dwellings in London, Liverpool, and other districts. While the company is thus doing a beneficent work, it is a business undertaking, and pledged to make its plans profitable to the shareholders as well as honourable to them. With limited capital, and without the aid of Government loans, the company has paid 7½ per cent. In these days, when the people are becoming conscious of the error of suffering the existence of houses of "immoral construction," it is creditable to this company that it builds no houses of less than five rooms. The tenant pays only 4s. 6d. per week for a five-roomed house, including scullery and cellar additional. It is hoped that before the next annual meeting 200 more dwellings may be erected by the company. Mr. Baxter Langley, having commented on and explained the report, the meeting was ably addressed by Mr. Hugh Birley, M.P. for Manchester, and by Mr. William Pare (long connected with the co-operative movement), Mr. A. A. Walton (of Brecon, and who had been much engaged in arbitration and conciliation), Mr. Illingworth (M.P. for Knaresborough), Mr. Kelsall (superintendent of the Company's buildings at Manchester), Mr. A. Bishop (plasterer, and one of the Company's tenants); and the Chairman (Lord Shaftesbury), in conclusion, delivered a most eloquent address on the good such companies were doing and would do for the advancement of public and social morality. On the motion of Mr. Joseph Leicester, seconded by Mr. Edward Holden, the largest shareholder of the company, a vote of thanks was passed to the chairman, and the proceedings terminated.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

THE fourth annual general meeting of this Institution was held on Tuesday week, the 28th ult., at the office, 14, Bedford-row, W.C. Mr. Benjamin Hannen (Holland and Hannen), the President for the ensuing year, in the chair. There was a good attendance.

The Chairman, in moving the adoption of the report, remarked that though the increase of the subscriptions received during the past year was but little over the amount received in the preceding year, the fact that there was an increase in spite of the war on the continent (which has affected all charitable institutions), and of the depressed state of the building trades, was a very gratifying one. He approved of the plan of granting pensions only to the amount of one half the annual subscriptions received, and of funding all donations, which formed a good groundwork for the permanent relief of the pensioners of the Institution. With regard to the Asylum Fund, he said he noticed that the rules stated that the objects of the Institution were the relief of the decayed builders' clerks and the maintenance and education of their children. The name "Asylum" Fund, he remarked, seemed to suggest something in the shape of almshouses, but upon that point the builders were more likely to have correct views than most societies, and they had come to the conclusion that pensions granted to their decayed members was the way to effect the greatest good with the means at their disposal.

Mr. H. T. Boyes, in seconding the adoption of the report, thanked Mr. Hannen for his remarks about the Asylum Fund, which should, with more propriety, be called the "Orphan" Fund, and explained that there was a rule that when this fund reached £1,000, a general meeting should be held to consider its appropriation. A motion had been made about eighteen months ago that life presentations in one of the existing orphan asylums should be purchased in the names of the President or Trustees, and that by means of life insurances upon those names the Institution should have perpetually the means of renewing such presentations; the cost of the first purchase would thus be the only outlay required, and he hoped still that this proposition might be entertained by the members of the Institution, and education afforded to the children of some of the pensioners.

Mr. Thos. Stirling said he hoped there would be another election of pensioners in November, and announced that Mr. John Waldram (Hill, Keddell & Waldram) was willing to give two guineas to the unsuccessful candidate at this election, provided four other gentlemen would do the same.

The motion having been carried unanimously, the officers for the ensuing year were re-elected.

Mr. Alfred R. Smith then proposed various alterations in the rules, so as to admit the widowed mothers of builders' clerks within the pale of eligible candidates for relief, remarking that one who had been entirely dependent on a son for support would be in as bad a position as a widow, and that every circumstance tended to

show that the relief would not be required for so long a period as in the case of a widow, the majority of whom would be comparatively young.

Mr. WARD objected that it was entirely altering the objects and principles of the Institution, and that in its present youth it was taxed sufficiently to meet existing claims.

Considerable discussion took place, in which Messrs. Marcus Bourne Newton, Thos. F. Cooke, R. Ball, and H. I. Wheatley took part, several of the speakers expressing great sympathy with the objects of Mr. Smith's propositions, which were severally brought forward and negatived.

A cordial vote of thanks to Mr. Thos. Stirling for the kind and valuable assistance he had rendered to the society, and another to Mr. Hannen for his able conduct of the business of the meeting brought the proceedings to a conclusion.

COMPETITIONS.

BIRMINGHAM ASSIZE COURTS.—Our Birmingham correspondent informs us that twenty-seven sets of designs have been sent in by competitors, and Mr. Waterhouse is appointed to advise. Our correspondent is not inclined to think that Classic will be adopted; and he even doubts whether the building will be erected at all, as the town has its hands full.

WHARFEDALE POOR-LAW UNION.—THE NEW WORKHOUSE PLANS.—On Friday last a special meeting of the guardians of the Wharfedale Poor-law Union was held at Otley, for the purpose of selecting a plan for the new workhouse out of twenty designs which had been furnished. The *ex-officio* guardians present were — Captain Dyneley, Mr. F. Darwin, and Mr. Fawkes, together with thirty-three of the elected guardians. The chairman (Mr. Thomas Denison, of Yeadon) presided. The report of the Building Committee was read, in which plans bearing the mottoes "Alpha," in black, and "Economy," in blue, were recommended for the first and second prizes respectively. It was moved and seconded that the report should be adopted. A good deal of discussion ensued, and various amendments were submitted. Ultimately, however, the original motion was carried. The mottoes of the various plans were then opened, and it was found that the designs bearing the motto "Alpha" in black had been sent in by Messrs. C. S. & A. J. Nelson, of Leeds, to whom the first prize of £50 was awarded; Mr. C. E. Taylor, of the firm of Taylor & Garthwaite, of Bradford, the author of the designs bearing the motto "Economy" in blue, being entitled to the second prize of £25. The following is the list of competitors:—Mr. E. W. Stephens, London; Messrs. Hope & Jardine, Bradford; Mr. J. W. Morris, London; Messrs. Webbe & Wheeler, London; Mr. J. F. Cobb, Newport; Mr. John Walker, London; Mr. R. K. Blessbrey, Middlesbrough; Messrs. Robinson & Marshall, Bradford; Mr. T. Ambler, Leeds; Mr. Alex. Stenning, London; Mr. W. Hill, Leeds; Mr. James Fisher, Birkenhead; Mr. Chas. Fowler, Leeds; Mr. R. B. Dixon, Darlington; Mr. Thomas Clark, Bradford and Yeadon. Two of the designs, bearing the mottoes "Wharfe" and "Utility," had not the names of their authors accompanying them.

SCHOOLS OF ART.

NOTTINGHAM.—The annual meeting of the Nottingham School of Art was held last Thursday week under the presidency of Lord Belper. The annual report was of a most satisfactory character. The number of students who attended the school during the past year was 503, showing an increase of 91 since the previous year. The particulars of the numbers attending each class, and the occupations of the students, &c., are duly set forth in the report. The general work of the school has been considerably in advance of any former years, as will be seen by the Government reports. The number of works sent up to London for inspection was 1,800, or exactly 50 per cent., more than the average proportion per student throughout the country. A much greater proportion of the works were in the advanced stages than in the previous year. There were 292 works in the higher stages of instruction, and 1,508 in the elementary stages. The school has for the third consecutive year taken the highest number of prizes among Provincial Schools, a result due to the ability and energy of the head master, Mr. Rawle, who for the three years that prize bonuses have been given by the Government, has taken a greater amount than any other master in the country.

PARLIAMENTARY NOTES.

THE NEW PUBLIC OFFICES.—Lord J. Manners asked the First Commissioner of Works on Monday, when it was intended to remove the block of houses between Parliament-street and King-street, facing the new Home and Colonial Offices.—Mr. Ayrton said that a portion of the buildings in question were now occupied as public offices which were very much needed, and the other portion was occupied under a special arrangement, so that the whole building could be pulled down as soon as the new Home and Colonial Offices were fully erected. The back part of it had already been demolished, but there was no object in pulling down the front part at present. —Lord J. Manners asked whether the thoroughfare at that point did not require to be widened.—Mr. Ayrton said that point involved the question whether a portion of public land was to be given up for the purpose of widening the street. There was no Act of Parliament which directed or authorized any such application of the property. Probably the best method of effecting the widening of the street would be by retaining the land in front of the new Home and Colonial Offices.

INDIAN COLLEGE FOR ENGINEERS.—Mr. Dickinson, on Thursday week, asked the Under Secretary of State for India what would be the charge on the revenues of India of the proposed College for Engineers; what the building will cost; what would be the annual cost of the establishment; and whether it is in contemplation to attach any and what retiring pensions in favour of professors or others employed in the institution.—Mr. Grant Duff: There will be no charge on the revenues of India on account of the Engineering College; the fees will be slightly in excess of the charges, including interest on the buildings and plant, say on 90,000*l*. There will be 11 professors and instructors on salaries varying from 700*l*. to 300*l*. per annum. Of these nine will be entitled to pensions under the provisions of the Superannuation Act, and two will not be entitled to pensions. If my hon. friend would like the figures here they are:—Annual sanctioned charge for college, as per regulations of Secretary of State in council, 18,350*l*.; interest on buildings, &c., say, 90,000*l*. at 4 per cent., 3,600*l*.; total, 21,950. Fees, 150 students at 150*l*., 22,500*l*.; difference, 550*l*.

Building Intelligence.

CHURCHES AND CHAPELS.

HALIFAX.—A new Unitarian chapel is to be built at Halifax, from the designs by Mr. Davis, of Leeds. The church consists of nave and transepts. There will be a town and spire rising to a height of 116ft. The contracts for the new building are all let to local tradesmen.

SALISBURY DIOCESAN CHURCH BUILDING ASSOCIATION.—The annual meeting of this Association was held at Salisbury on Tuesday week. From the report it appeared that six applications for aid had been made to the Association during the year 1870, two on behalf of new churches, and the remainder towards restoring or enlarging existing buildings. In all these cases grants have been made amounting in the aggregate to £515, meeting an estimated expenditure of £8,285, and helping to provide 718 additional sittings. The new churches for which aid was granted were one for the extra-parochial district of Chute Forest, and a new district church at Portland, and those aided in being restored or enlarged were Christ Church, Warminster, Iwerne Minster, Tisbury, and Britford. The following churches which have received assistance from the Association have been reopened for service during the year—viz., Churches consecrated: S. Thomas, Trowbridge, West Lulworth, and Hinton Martell; Churches restored: Bloxworth, Cerne Abbas, Odstock, Silton, Turnworth, Westwood, and Whiteparish. The diocesan architect has inspected, with a view to future restoration, the churches at Stower Provost, Milborne S. Andrew, Erlestoke, and West Harnworth.

BUILDINGS.

ATHENÆUM, CAMDEN-ROAD.—The hall—the portion at present being built—will be about 60ft. by 50ft., formed by a centre part 33ft. high, with wings irregular on plan, 20ft. high. The ceiling is semi-octagonal in section, with circular ribs of principals dividing it into five bays in its length. The wings are ceiled by arches transversely from the side of the centre part, so that the irregularity of plan is only noticeable in the lower part of the room. There will be four doors as exits from the hall, one at each corner of the room. Under the platform end of the hall will be the retiring rooms, and a staircase down will communicate with them, as well as give direct communication underneath from one side of the platform to the other. The building, externally, will be of brick, with red brick plinth strings, cornices, and architraves, the enrichments being of red terra cotta. The interior and exterior of the building will be bold and simple in design, of Classical character. The contract for the hall is £1,579, and Messrs. Gough and Lawton are the contractors. The other part of the building, which will form the second contract, will comprise a reading-room, 18ft. high, library and cloak rooms on ground floor, and a Mezzanine and first floor of rooms of various sizes, as well as a basement devoted to the keeper's residence, &c. The architect of the building is Mr. Frederick R. Meeson.

CHISELHURST.—The foundation-stone of a new asylum for aged governesses was laid at Chiselhurst on Saturday last. The building is being erected under the auspices of the Governess's Benevolent Institution, and the site is near the old church, on the north side of the road leading from Chiselhurst Common to S. Mary Cray. The style adopted by the architect, Mr. M. Wyatt, is a combination of Elizabethan and Tudor, the low pitch unavoidable in a row of separate cottages or dwellings being relieved by a prominent gable front and porch to the centre house, which is to be occupied by the lady superintendent. When complete, the asylum will form three sides of a quadrangle, consisting of twenty-four separate dwellings, each of which is designed for one annuitant and her servant, and will comprise four rooms, kitchen, scullery, and the usual offices. A verandah will shelter the front entrances. The cost of the twenty-four houses is estimated at £15,000, a contract for the erection of the first half having been taken by Mr. Tongue, of Plumstead, for about half that sum.

OXFORD.—The foundation-stone of a new school for boys, for the district of Cowley S. John, was laid on Tuesday last by the Rev. Father Grafton. The school will measure 70ft. long by 30ft. wide, and comprise two class rooms each 16ft. square, and a general room, with lavatory and the usual offices attached. The building will be of brick, with stone dressings to the windows and an open timber roof, covered with red tiles. The total cost is set down at £1150. The architect is Mr. Buckeridge, the builders Messrs. J. Castle & Co.

SWANSEA.—The alterations and additions to the Guildhall, which have been some months in progress under the direction of Mr. C. J. Phipps, F.S.A., architect, of London, are now complete, and the Assize Courts were opened by the judges on Tuesday. The works comprise an entire rearrangement of the internal fittings in both Courts, with galleries for the public and Grand Jury; a new wing on one side, with two private rooms for judges, rooms for High Sheriff, the Bar, and others; on other side, Grand Jury rooms and residence for hall keeper; on ground floor the office, for the Corporation officials have been doubled, and under courts twenty separate cells constructed, from corridor of which are staircases to docks in both courts; separate rooms are provided for the Petty Jury and witnesses in each court, with all proper conveniences. The contractor has been Mr. John Everal, of Great Malvern. The cost, exclusive of furnishing, has been just over £3,000. Mr. Phipp's plans were chosen in competition.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

THE *BUILDING NEWS* SKETCH BOOK.

J. H., a contributor, says "Would it not be better to give, the polling, or rather, voting for the prizes in Friday's issue? Politicians know the value of ascertaining the state of the poll as it progresses. I don't anticipate having a single vote, and therefore don't intend to vote for anybody else." We think it would be a wrong principle to declare the state of the poll before it is decided. "J. H." is equally wrong in his reason for not voting. He simply abdicates his functions because he thinks his own sketch is not up to the mark. We may tell him, however, that he has a vote recorded in his favour. He and others are informed that the poll closes on Wednesday evening next.

RECEIVED.—J. N. L., Vinis, H. G. W. D., C. L., F. R. M. T. W. S., E. G., J. H. C., O. N., J. P. S., C. B. A., J. H., W. W., E. F., S & Son, S. H & Co., J. A., Art Engraver, C. R. M., J. H. W., E. P. N., J. J., E. S., T. J. T.

J. C. J.—The MS. did not come to hand.

W. J. ROLFE.—Next week.

G. T. CHOUGH.—Thanks.

W. R. WILKINSON.—Mr. Godwin's design for the Bristol Assize Courts will be given.

J. HICKS.—Sketch to hand.

UTILE DULCI.—Perspective and plan to hand.

Correspondence.

CENTRAL HALL OF ARTS AND SCIENCES.

To the Editor of the Building News.

Sir,—I beg to decline all controversy with Mr. Redgrave, and to state that I much regret that anything in my letter, inserted, p. 154, should have caused such a paroxysm of temper as almost to make him forget the customary courtesy usual between gentlemen. Also, that I consider him justified in making use of any means in his power to defend the handiworks of himself and his friends from any supposed attacks by me. I say supposed, decidedly, because there is no word in my communication derogatory of that "magnificent building," erected and completed entirely by the people's money

I complain only of misuse and misnomer; for, as at present arranged, it is wholly unfit for scientific lectures, as future experience will amply demonstrate. In regard to the Coliseum at Rome, which seems to have somewhat shattered Mr. Redgrave's nerves, I beg to inform him that I resided for some years in its immediate neighbourhood, long before he himself was born. As I have been challenged I intend, at a future period, with your permission, to offer some further observations upon the Central Hall of Arts and Sciences, that is to say, when it shall have been fully opened to the public.—I am, &c., C. E.

THE *BUILDING NEWS* SKETCH BOOK.

Sir,—In respect to the voting for the "Sketch Book" prizes, allow me to suggest that every contributor be compelled to record his votes, or be disqualified from receiving a prize; otherwise those who vote will lessen their chances of gaining a prize by increasing the votes of their opponents, who perhaps have not voted.

I should like to understand the exact meaning of the statement, "the least number of votes will gain the third prize." Suppose several sketches get no votes. How will the third prize then be given? Will the letter of the text be adhered to, or will no votes be counted lower than one? If the latter case, will the arbitrator choose the best or the worst of the no-vote sketches?

A suitable understanding as to the above queries would, no doubt, guide contributors in their voting.—I am, &c., Contributor.

[We don't see how we can *compel* contributors to vote, but it is only fair that they should. The phrase "the least number of votes will gain the third prize, is not a happy one. What, of course, is meant, is the third prize will be awarded to the sketch which has the third highest number of votes.—Ed.]

Intercommunication.

QUESTIONS.

[2141] ½ HOUR GLASS.—Can any of your correspondents kindly oblige me with a rough sketch of an hour glass of about the middle of the fifteenth century?—Time.

[2142] COMMUNICATION WITH GARDENER'S HOUSE.—My gardener's house is, say, 300 yards from my house, and I wish to have some communication with it in case of him being wanted in the night, and in consequence of the roads and shrubberies, if I use bell-wires I cannot have them acting for long, and having seen somewhere that by laying down a small tube and having a piston at the house end, and forcing in the air I could ring a bell, Can you or any of your correspondents tell me how I could do this, and oblige?—Camjee Wadjee.

[2143] SEWER AUTHORITY.—Can any readers oblige by giving their opinion on the following?—The sewer authority of A construct a sewer which is declared to be a private improvement, and order the same to be charged upon the adjoining house-owners and occupiers by rates extending over six years. Subsequently, the sewer authority make an order upon the overseers of A for payment of the money spent in making the foregoing sewer, to be paid out of the poor-rate. No notice is given to the overseers that the money was wanted for the purposes of this private improvement. The overseers pay the amount ordered. After payment by the overseers the sewer authority call upon the persons whose properties adjoin for a private improvement rate, and summon them, upon default, before the magistrates. Is it not a fatal objection to the rate that it is already paid? There was a large drain (sufficient for the purpose) before the new sewer was made. See the effect of Section 45, of Public Health Act, 1848, incorporated with Sewage Utilisation Act, 1865. There were other irregularities. Cannot an objection be raised before the magistrates that the rate is bad? The statutes bearing upon the subject appear to be the Sanitary Acts, 1866 and 1868, the Public Health Act, 1848, s. 90, *et seq.*, and the Sewage Utilisation Act, 1865.—W. W.

[2144] BLUE LIAS FOR PLASTERING.—Will some one kindly give some information respecting the use of the above on brick and lath for finished walls and ceilings? If economical as compared with chalk lime; and if necessary to finish off with setting coat of chalk lime putty; if there is any advantage in its powers of resisting damp? I have equal facalities for getting either.—Lias.

[2145] BURNING CLAY.—Will some one kindly give me the process of burning clay into ballast, with the view of using the coarse on paths and the fine on new made garden?—Burnt Clay.

[2146] BRICKS.—Will some correspondent kindly inform me where the bricks used in the erection of Mr. Street's church, St. James-the-Less, Garden-street, Westminster, were manufactured?—A. B.

[2147] HERRING-BONE BRIDGING.—Will some reader kindly give an explanation of what "herring-bone ridgin" is?—Ixion.

[2148] ANTILL'S PATENT TRAP.—Can any of your readers tell me where Antill's patent trap for sinks is to be obtained, and the price? Also, if it is satisfactory in preventing stench?—A Beaver.

[2149] PRICE OF BRICKWORK.—Can any of your readers kindly inform me of the price of brickwork in the neighbourhood of West Bromwich?—Inquirer.

[2150.] SURVEYING DILAPIDATIONS.—Will some of your readers kindly say if a rector or vicar, as the case may be, is liable for the dilapidation of chancel archway; or whether this is a portion of the fabric, which together with the nave, &c., the churchwardens are bound by law to look after and keep in decent repair? Again, with regard to mortuary chapels, &c., separated by archways from the chancel, whose duty is it to keep in repair the chapels, &c., and said archways? Will also one of your readers, who has had a good experience in valuing ecclesiastical dilapidations, say if it is customary for surveyors to walk round and examine the state of every fence belonging to the benefice glebe lands?—A Reader.

[2151] PRESERVING PENCIL DRAWINGS.—May I take the liberty of asking you or some of your readers to kindly inform me what will prevent lead from rubbing off a pencil drawing which has recently been finished, and an explanation of making and using it?—W. D. J.

[2152] VANISHING-POINT.—Can you kindly inform me how to find the vanishing-point of interior perspective?—C. A. Priestley.

[2153] DAMP.—Can any one recommend a cure for damp exuding on the plaster of a press in an outside wall, the back walling of the press being one brick thick, with hollow space between? Is there any composition which, applied to the plaster inside, would cure the evil?—W.

[2154] ISOMETRICAL DRAWING.—Will your correspondent, "M. G. R" kindly inform me where T. Sopwith's, F.G.S., "Treatise on Isometrical Drawing" can be obtained? Pupil.

[2155] NEW CORPORATE BUILDINGS, BIRMINGHAM.—Will any of your readers inform me whether the competition designs for the above will be publicly exhibited; if so, when, and how admission is to be obtained?—Staff's.

[2156] OLD AND NEW BRICKWORK.—What method should be adopted to tie in the new with the old brickwork when carrying up a chimney-breast against an adjoining party wall?—Tyro.

[2157] SECURING PLATES.—I shall be glad to know methods of securing plates when inserted in cases of repairs, and the underdrawing is lashed to spars?—M. P.

[2158] LARGEST STONE DOME.—What is the diameter of the largest stone dome?—X. Y.

[2159] ANCIENT STONE SPIRES.—What is the average thickness of the shell of ancient stone spires?—D. M.

REPLIES.

[2134] REMOVAL OF ROSE TREES—No.—F.

[2136] SOLE CONTRACTS.—I beg to assure "A Subscriber" that he is very properly advised. I speak from experience, being in practice as a surveyor and valuer. Were he to let the works solely to one contractor that contractor would re-let the different branches (excepting his own, which would probably be that of a carpenter and joiner), and add 5 per cent. to the several sums for his trouble; and probably the masters of those different branches would insure themselves against risk of failure, or otherwise, of the first contractor, by putting high prices. There is everything favourable to the proprietor in letting the works separately, while it entails extra labour, expense, and consequently responsibility upon the architect.—Surveyor.

[2136] SOLE CONTRACTS.—Much can be adduced in favour of both methods, but from being engaged in working several varieties in contracts would strongly advocate sole contracting, deeming it less costly and easier worked. In sole contracting one responsible person alone has to be dealt with; but the alternative is "confusion worse confounded," involving multiplicity of contracts, drawings, quantities, specifications, arrangements, superintendence (amounting to surveillance), annoyance, certificates, payments, and adjustment of accounts, and involving a total annihilation of anything like order, method, or responsibility. I could enumerate several converts, erst-while sticklers for the separate trade contract mode. Sole contracting is the safest, confers most benefit on all concerned, and is gaining, certainly not losing ground.—F.

[2136] SOLE CONTRACTS.—"Subscriber" could not do better than take the advice of his architect, and by all means let the work to separate contractors; he will find it more economical, and better, indeed, for all parties concerned. I used to let a great deal of work to sole contractors, but I never do it now, and don't intend again, because some time ago I estimated for joiner, plasterer, plumber, and slaters' work from one individual (the joiner being sole contractor); the amount estimated was about £800, inclusive of the ground works. After the job was squared up, finished, and paid, the joiner, who was sole contractor, became bankrupt, and the plumber, plasterer, and slater had to take 5s. per pound for their share. This is one great evil arising out of sole contracts in Scotland.—Right Wrangs Naebody.

[2137] FOUNTAINS.—"J. F. S." will have to pump the water up to a cistern, elevated about 22ft. above level of ground at fountain, and if he then connects the cistern with fountain by a pipe, he will get sufficient force to throw the water to the height he requires.—A. W.

Our Office Table.

Society for the Encouragement of the Fine Arts.—On Thursday week, the 2nd instant, Mr. Hyde Clarke, D.C.L., delivered a lecture at the rooms of this society, 9, Coudnit-street, Regent-street, "On the Common Elements of Beauty in Race in Georgia, Circassia, the Holy Land, and the British Isles," in which he brought forward a new theory of the principle on which a general standard of beauty in art has been accepted in Classic times and in the modern age. Dr. Chr. Dresser presided. [A full report of the lecture is in type, and will appear next week.]

Imparting a Yellowish Hue to White Marble.—M. R. Weber has made known through a German journal, the hitherto unknown fact that alcoholic solutions of perchloride of iron are not precipitated by carbonate of lime, and may therefore be applied in different degrees of concentration to impart a more or less deep yellow hue to white marble.

Free Lectures on Geology.—Dr. Cobbold, F.R.S, will commence a course of twelve lectures on geology (being the Swiney Lectures), to-morrow (Saturday) evening, at eight o'clock, at the Museum of Practical Geology, Jermyn-street. The lectures will be continued on successive Saturday evenings. The admission is free, and architects' assistants and pupils and workmen connected with the building trades will do well to embrace this opportunity of instruction in a science which has considerable bearing on their pursuits.

The Site of Newgate Market.—Last week the site of the old Newgate Market was offered for sale by Messrs. Wiostanley and Horwood, under directions from the Markets Improvement Committee of the City of London, and was sold in one lot for £20,000, subject to the conditions approved by the committee, and also by the Dean and Chapter of S. Paul's, by which arcades or passage ways 10ft. in width are reserved from north to south, and from east to west.

Improved Industrial Dwellings.—A week or two ago Miss Burdett Coutts entered into an agreement by which all the land remaining vacant on the north side of Columbia Market, and also the small unoccupied piece on the south (adjoining Angela-gardens) will be built over with good three-storied houses during the present year. We (*Hackney Express*) now learn that Miss Coutts has accepted an offer for a lease of 330ft. of frontage on the south side of Crabtree-row made to her by the Improved Industrial Dwellings Company. The company are to have possession of the site on the 25th inst., and within twelve months contract to complete their buildings, at a cost of not less than £15,000.

The Gray's Inn-road Burial-ground.—A movement has been set on foot in the Holborn district, under the anspices of Dr. Stallard and the Rev. Dr. Worthington, of Holy Trinity Church, having for its object the removal of what (as Dr. Stallard said) is a scandal to the parish, viz., the present condition of the Gray's Inn-road burial-ground. It is proposed to utilise a portion of the ground for the erection of schools for 700 children, and to lay out the remainder as a public recreation-ground. Steps are being taken to procure the necessary Act of Parliament.

Metropolitan Tramways.—On Saturday last the formal opening of tramway communication between the eastern end of Greenwich and the Newcross road, near to Peckham, took place, the directors of the Pimlico, Peckham, and Greenwich Tramway Company, together with the whole of the members of the Greenwich District Board of Works and other parochial officials who had been invited, assembling on the occasion.

Progress of the Thames Embankment.—On Saturday last the loop line of the Victoria Embankment running from Somerset House on the west, to the Temple-gardens on the east, was nearly completed, only a few more stones having to be laid down and the roadway rolled. There is now an approach from Surry-street on the west, and from Arundel-street and Essex-street on the east end of the loop line. The approach from Norfolk-street, the principal thoroughfare from the Strand, is at present in rather a rough state, but it is open for pedestrians, and has already proved a great convenience.

The New Sovereign.—The Right Hon. the Master of the Mint is to be congratulated on his

last achievement, says the *Art Journal*. Congratulated, that is to say, if the new coin is to be regarded from one point of view, and weighed in one particular balance. If it be desirable that the gold currency of Great Britain should be made the symbol of the adoption of a certain set of views by the administration—if it be wise to proclaim to the world, by the widely-circulating testimony of the English sovereign, that the rulers of England are contentedly or contemptuously ignorant of fine art—if it be satisfactory to furnish abundant proof that, in the direction of the English Mint, not only artistic talent, but also mechanical excellence, are entirely disregarded—the new sovereign must be held to be a great success. For this is what it does, upon the face of it—it bears the same relation to the noble gold coins of the best period of our currency that a print from a slovenly cliché bears to a proof engraving. It is a crucial instance of the difference between what is cheap and what is good. It betrays an equal ignorance of the laws that so regulate a coinage as to give it historic value, and of those which regard either its æsthetic propriety or its artistic merit. The only thing left for its originators to regret is that existing prejudices have prevented them from stamping their new issue in aluminium or Abyssinian gold.

Liverpool Architectural and Archæological Society, Colquit-street. — The tenth meeting of this session was held at the Royal Institution, Liverpool, on Wednesday Evening last. A paper was read by Mr. Jas. M. Hay, "On Entasis: its Use and Misapplication in Design," accompanied by illustrations.

White's Club-house. —The sale of this freehold property took place on Tuesday, at the Auction Mart, City, by Messrs. Chinnock, Galsworthy, & Chinnock, of Waterloo-place. As an investment, it appeared that the rental was £2,100 per annum for eleven years, when the lease to the club expires. The sum realized was £46,000, the purchaser being Mr. H. W. Eaton, M.P. It was at first supposed that the club had secured the premises in which they have been so long located, but this does not appear to be the case, Mr. Eaton having purchased the property for investment.

City Improvements.—At the meeting of the City Commissioners of Sewers on Tuesday last, it was announced that at a meeting of the Works and General Purposes Committee of the Metropolitan Board of Works, held the preceding day, it was agreed to pay half the cost of acquiring five houses for widening Queen-street, Cheapside, between New-street and Panceras-lane. The total purchase-money required was estimated at £25,334. The Committee would also recommend the Board to pay half the cost of purchasing two slips of land in Upper Thames-street for the proposed widening of the same. The Finance and Improvement Committee of the Commission were empowered, agreeably to their request, to negotiate for the purchase of property in Lombard-street, in order to set back the frontages of the premises Nos. 37 and 38 in that street.

Statues in the Church of S. Denis. —A French correspondent of the *Pall Mall Gazette* gives a list of the statues inside the Cathedral of S. Denis which have been injured by carelessness, bombardment, or pillage. The most curious accident is certainly that which happened to S. Denis. The statue of the good saint, who is popularly supposed to have crossed a river with his head under his arm, was decapitated by a shell. The statue of Catherine de Medicis has two fingers cut off and stolen, and a gash from a sabre on her hands. Henry II. has lost not only two fingers, but the big toe of his right foot; Charles VI. his right hand; Duguesclin the hilt of his dagger; Charles V. both hands and his sceptre; Charles Martel a finger; Pepin le Bref has had his sceptre broken; and Louis XVI., besides receiving a cut across the nose, has been deprived of both his thumbs.

Discovery of Additional Hot Springs at Bath.—A leakage having occurred in the hot springs of the King's Bath, some excavations have been made in Abbey-place, with a view of discovering the cause. At a depth of 22ft. one, if not two, new springs have been discovered, yielding 20 gallons at least per minute, at a temperature of 110 deg. A number of Roman remains have been found in the excavations, together with a flooring of lead half an inch thick, resting upon concrete. It is supposed, therefore, that these particular springs were used by the Romans.

MEETINGS FOR THE ENSUING WEEK.

Monday.—*Institution of Surveyors.*—Papers "On Tithes and Tithe Commutations." By Messrs. W. Sturge and J. Oakley. 8 p.m.

Royal Geographical Society.—"On Mr. Thomas Baines's Exploration of the Gold Region between the Limpopo and the Zambesi." By Dr. R. J. Mann.

Tuesday.—*Institution of Civil Engineers.*—"On Phonic Coast Fog Signals." By Mr. Alexander Beazeley, M. Inst. C.E. 8 p.m.

Wednesday.—*Society of Arts.*—8 p.m.

Thursday.—*Society for the Encouragement of the Fine Arts.*—"Heliotypy: its Application and Modes of Working fully illustrated." 8 p.m.

Friday.—*Civil and Mechanical Engineers' Society.*—"Some Small Domestic Engineerings." By Mr. W. Forsyth Black. 7.30 p.m.

Saturday.—*Associated Arts' Institute.*—Discussion, introduced by A. H. Wall. Thesis, "That the Aim of the Painter and of the Sculptor should be to represent Thoughts rather than Things." 8 p.m.

Saturday.—*Museum of Practical Geology, Jermyn-street, S. James's.* — Swiney Lectures on Geology. Lecture II. By Dr. Cobbold, F.R.S. 8 p.m.

Chips.

Paris was relit with gas on Friday last.

The meetings of the Associated Arts Institute will shortly be transferred to University College, Gower-street.

The second Exhibition of the Old Masters at the Royal Academy closed last Saturday, and has been even a greater success financially than the one of last year.

The programme for the opening of the Royal Albert Hall has been approved by Her Majesty the Queen, and will be found in our advertisement columns.

The laying out of the grounds round the Albert Memorial in Hyde-park is being rapidly accomplished, and great changes are being made in the walks and plantations of the Kensington-gardens.

The Architectural Selection Committee for the Exhibition of 1871 has now been raised to its full strength by the election of Mr. Fergusson, who had previously been nominated by the Architectural Exhibition Society, but had resigned when that society became extinct.

The Committee of Selection for Fine Arts in the forthcoming Exhibition have held several meetings this week, and have decided to reject a large number of the works which have been sent in.

S. James's tower, Taunton, which has been in a dilapidated state for some years past, is being pulled down. A fac simile of it is to be built. Mr. Spiller, the builder of the Taunton Church College and Exeter Railway station, is the contractor.

A new school has been erected at Holywell-green, near Halifax, under the superintendence of Messrs. Horsfal, Wardle, and Patchett, of Halifax.

A Bill to confirm a scheme under the Metropolitan Commons Act, 1866, relating to Blackheath, was issued on Monday.

Considerable alterations and improvements have been made in the arrangement and extension of the artillery officers' library and messroom at Woolwich.

Steps are being taken to erect a new Wesleyan chapel near the Archway-road, Highgate, in lieu of the iron building which has done duty for the last seven years. The contemplated outlay is £4,500.

New premises have been erected in New Market-street, Bradford, as offices for the Bradford Third Equitable Benefit Building Society, from designs by Mr. T. C. Heape, architect, Mr. A. Niel being the contractor.

A temporary small-pox hospital has been erected by the Westminster Board of Works in Millbank-street, and it was opened on Wednesday last for the reception for patients.

In the Consistorial Court at Wells, on Tuesday week, Dr. Wallis, the deputy-judge, granted a faculty for the erection of figures in the pulpit and nave of S. Mary's Church, Taunton, and also of opening four new windows in the chancel.

The Finance Committee of the Court of Sewers Commissioners for the City of London has been instructed to prepare a report upon the present financial position and future prospects of that body.

At their meeting on Tuesday last the City Commissioners of Sewers decided to pave Moorgate-street and Finsbury Pavement with three kinds of asphalte—the Val de Travers, Limmer's, and Barnett's, in order to test their respective merits.

Dr. Gibbon, the Medical Officer of Health of the Holborn District, has recommended that the provisions of the Artizans' and Labourers' Dwellings Act be enforced in the case of four houses in Brook-court, Brooke-street.

We are informed that the Prussian soldiers have done considerable damage to the sculpture at S. Denis, by chipping off portions of the fingers, toes, drapery, &c., of the statues, as mementos of their visit.

At length the City Commissioners of Sewers have resolved to build a mortuary upon the land secured for that purpose in Golden-lane, Barbican. The cost of the building will, it is estimated, be £5,800.

Timber Trade Review.

W. J. Mitchell (accepted)	£1100

CONTRACTS OPEN FOR BUILDING ESTIMATES.

Fawsley (Northamptonshire), March 13.—For the erection of farm buildings. Mr. Waters, Fawsley Estate Office.

Leeds, March 25.—For the erection of offices and warehouses, for Messrs. Goodall, Backhouse, & Co., Leeds. William Bakewell, architect, 12, East-parade, Leeds.

Leeds March 25.—For the erection of shops and warehouses, for Mr. G. Newby, Leeds. William Bakewell, architect, 12, East-parade, Leeds.

Whittlesey, March 18.—For restoring and re-seating S. Andrew's Church. R. Reynolds Rowe, F.S.A., architect, 10, Emmanuel-street, Cambridge.

Southport, March 15.—For the erection of S. Andrew's Church. W. Robson and T. Fisher, Hon. Secs.

Strand District, March 15.—For the supply of Yorkshire and other paving, granite kerb channels, and dressed granite, &c.; also for relaying and repairing the carriageways and footways within the Strand district. Thos. M. Jenkins, Clerk to the Board, offices, 5, Tavistock-street, Covent-garden, W.C.

Strand District, March 15.—For the supply of materials and the execution of jobbing and measured works required for the sewers and drains. Thos. M. Jenkins, Clerk to the Board, office, 5, Tavistock-street, Covent-arden, W.C.

Midland and London and North-Western Railway Companies (Ashby and Nuneaton Joint Railways), March 15.—For the erection of passenger stations, goods sheds, houses, and platforms at the following places, viz., at Measham, Market Bosworth, Shackerstone, Stoke Golding, Snarston, Heather, Hugglescote, Shenton, Higham-on-the-Hill. Secretaries of Ashby and Nuneaton Joint Railway Committee, Euston Station, London, N.W.

Leeds, March 15.—For the construction of a storage reservoir, at Springfield Mill, Farsley, near Leeds. S. Firth, architect, Undercliffe.

Leeds, March 15.—For a dwelling-house, in Lady Pit-lane, Hunslet. Richard Towse, architect, Dewsbury-road, Leeds.

Leeds Waterworks, March 17.—For the construction of a covered service reservoir, at Moortown. C. A. Curwood, Town Clerk, Leeds.

Leeds, April 3.—Building new bridge. Quantities supplied. Bridge Office, 19, Corn Exchange, Leeds.

Gloucester, March 20.—For the erection of a new chapel, day-rooms, and other buildings. Mr. Medland, the county surveyor, Clarence-street, Gloucester.

Henley Union, March 14.—For the erection of new school at the Union Workhouse, Henley-on-Thames. Nicholas Mercer, clerk, Henley-on-Thames.

Herefordshire, March 25.—For the erection of a school at Bromesberrow, near Ledbury. Middleton & Goodman, architects, 1, Bedford-buildings, Cheltenham.

Isle of Ely, July 25.—For an iron bridge across the river Ouse, at Littleport. F. M. Metcalfe, Clerk of the Peace, Wisbech.

Churwell, March 13.—For the erection of a new school, in connection with Mount Zion Chapel. Samuel Horner's, Little-lane, Churwell.

Convict Prisons, March 11.—For the supply of timber, deals, slate, lime, sand, bricks, lead, glass, wrought and cast iron, ironmongery, gas and water pipes, whitelead, oils, colours, &c., for twelve months. Directors of Convict Prisons, 44, Parliament-street.

Derbyshire, March 24.—For alterations and additions to the County Prison, Derby. Robert Griffiths, architect, Martin-street, Stafford.

Bicester, March 25.—For building a chapel at Fewcot, and a vicarage house at Stoke Lyne, both near Bicester. Rev. C. Marsham. Caversfield, Bicester, Oxon.

Bradford, March 15.—For works required in the erection of a terrace of fifteen houses, to be built near the Manningham Railway Station. Marsden & Bennett, architects, Popplewell's-chambers, Market-street, Bradford.

BANKRUPTS.

(TO SURRENDER IN LONDON).

Charles Castleman, Westbourne Park Villas, Bayswater, and Kingston, timber dealer and brick manufacturer, March 14, at 11—Frederick Chalwick, Sellwood-terrace, Fulham-road, builder, March 22, at 1—George Wood, Vorley Villas, Junction-road, Upper Holloway, late brick merchant, March 24, at 12.

(TO SURRENDER IN THE COUNTRY).

Abel Richard Chapman, Heigham, builder, March 16, at Norwich — Daniel Cunningham, Leicester, plasterer, March 14, at Leicester—Frederick Haythorpe, Ramsey, builder, March 18, at Peterborough—William Topham, Harrogate, builder, March 16, at York—Joseph Seal and Joseph Everard, Nuneaton, brickmakers and stone merchants, March 20, at Coventry.

BANKRUPTCY ANNULLED.

Charles Walter, Shardeloes-road, New Cross, builder, Feb. 24.

PUBLIC EXAMINATIONS.

April 19, B. E. Abery, London-lane, Hackney, builder —April 13, H. Stevens, Swaffham Bulbeck, Cambridgeshire, builder.—March 18, H. W. Webster, Kings-road, Bedford-row, builder—March 20, H. Parker, York-place and Marsh, near Huddersfield, joiner and builder—March 21, J. Potter, Kate's-hill, Dudley, engineer.

DIVIDEND MEETINGS.

March 20, W. Brooks, Burnley, plumber—March 21, J. Rhind, Cardiff, civil engineer—March 21, C. Evans and T. J. Jones, Newport, timber merchants—March 17. W. White, Poole, Dorset, builder—March 20, T. Morley, Brighton, builder.

DECLARATIONS OF DIVIDEND.

W. Bell, Gateshead and Tynemouth, paint manufacturer, div. 8s.

PARTNERSHIPS DISSOLVED.

Butt & Perfect, Ladbrook road, Notting Hill, builders, —Morriss & Kett, Finchley, builders—Kerr & Padget, Bradford, ironfounders—Platt & Malpass, Madeley Heath and elsewhere, brick and tile manufacturers—Brown & Pullan, Bradford, painters and paper hangers—Simmons & Son, Manchester, builders.

THE BUILDING NEWS.

LONDON, FRIDAY, MARCH 17, 1871.

METROPOLITAN RAILWAY BUILDING COMPETITION.

THE premium of 50 guineas for the best design for laying out the South Kensington Estate, has been awarded to Mr. H. Elliott. In this locality there are many houses unlet, from having been built, as Mr. Elliott believes, upon an unpopular plan—upon the smallest possible piece of ground, and in too close proximity to stables—in fact, upon the usual too greedy scale generally adopted by speculating builders. He therefore recommends to the Company a more liberal scheme, and we should be glad if he be able to prove, as he anticipates, that it would be more popular. It is that which to a certain extent has been adopted around Notting-hill, of having a common large garden and square, and a special small garden to each house, avoiding the narrow strips of garden too much in vogue hitherto elsewhere, and the unsightly and unsavory mews, cheek by jowl with the houses. He forms a roadway 45ft. wide at the Cromwell-road end, running with an easy curve to join one that has been partly begun upon the adjoining Broodwood's estate. This would give a fine crescent of houses; mews for which, giving stables for about half the houses, are placed where they would be handy and unobjectionable. The houses are of the first-class, with staircase in centre, permitting more equal-sized rooms and larger hall than in houses with a straight flight opposite the door. These are estimated to cost a builder £2,600. Their frontage would be 22ft. 6in. each, and is calculated at from 33s. 6d. to 37s. 6d. per foot., amounting to £1,835; and with 23 stables to £1,950 6s., and deducting interest on cost of roads and gardens, to £1,855 6s., the capitalised value, at 31 years' purchase, being £57,514 6s. The rack rental value of the houses would be £300 less; ground-rent, £52 10s.; and as in this locality leaseholds are generally sold at 15 years' purchase, the leasehold value would be £3,712, giving a net profit of £900; and with probable improved ground-rent, about £1,180—the amount is said by Mr. Elliott be the profit made usually by builders building upon a good plan. The general arrangement in this case is certainly a good one, as also is that of the houses; the elevations are unfortunately mediocre and commonplace.

Messrs. Mileham and Kennedy have a pleasantly-arranged, but less economical plan for laying out this estate. Most of their houses are upon the ordinary plan with objectionable excrescences at the back; and a few others, shown with wider frontages and offices on the ground floor, behind them, have poor and ill-lighted staircases, and no halls.

Mr. W. H. Lockwood shows a similar arrangement to Mr. Elliott for the plan of his houses, well-worked out, but the style adopted is a starved and cranky description of Gothic, and the general plan and irregular triangles of closely-set double-detached villas, enclosing a too-confined common garden, is inferior. Mr. Klein sends two plans for this estate, one of which gives a good crescent turned in the opposite direction to Mr. Elliott's, looking in front upon an ample pleasure ground adjoining the railway cutting, but the backs look upon mews and confined courts.

Mr. Elliott has been also fortunate enough to carry off the premium of 50 guineas for the Linden Grove Estate.

This property has but one entrance, Linden Grove being a *cul-de-sac*. Mr. Elliott, jealous of the retired character of the site, gives it but one entrance, immediately opposite the railway station, leading up to a semi-circular road, with crescents of houses on either side, with common gardens to their rear. He advocates this form as giving more available frontage, affording larger open spaces, and more attractive and sunny than parallelograms or straight roads, besides being particularly adapted to the site in question. He has given his elevations a character—"being a mixture of Elizabethan and Queen Anne's styles," with red brick and stone dressings, and high roofs, which is certainly picturesque. The cost would be about £2,200 per house; the value per foot frontage is estimated at 33s. 6d., or about £40 per house. By this treatment the estate is made to yield a capitalised sum of £47,910.

Messrs. Matthews, Quilter, & Cutler have a plan more suited to the country, with sixteen double villas scattered round a serpentine road. In Linden-grove we fear such gardens would be rather unpractical. Mr. Charles Hayward, of Westbourne-park-villas, Mr. Klein, and others, adopt a parallelogram arrangement, not equal in merit to the above.

The premium of 50 guineas for the Campden Hill Estate has been carried off by Mr. C. J. Richardson. His plan has been made with the view of injuring as little as possible Campden House. Villas of about £200 to £250 annual rental, with gardens, are to be built round those premises.

The estate, it is supposed, would realise thus £950 per annum. We do not notice any particular merit in this plan. Mr. Klein also reserves Campden House, but rakes it with the windows of two rows of houses on either side of its grounds.

Mr. Elliott has been even more considerate for the existing building, putting fewer villas around it; but we fail to see how he can bring his annual value to a higher amount than Mr. Richardson—viz., £1,280. We notice, however, £200 difference in the rental set down for Campden House itself.

It is noticeable that none of the premiated designs are of the too-greedy order, and that apparently the judge, Mr. Hunt, has decided upon what he conceives would be a liberal and even æsthetic treatment.

The premium of 50 guineas for the design for laying out the Praed-street Estate has been adjudged to Mr. Thos. C. Sorby, with a plan giving accommodation for small dwellings for operatives, and shops.

On each side of the station, opposite the Great Western Hotel, he has placed two-room shops, treated as an arcade, "to form a pretty feature," and to be occupied by tobacconists, newsagents, &c., &c.

In a narrow space over the entrance to the tunnel he proposes "neat panels in the walls for permanent advertisements," which we hope he will be also able to render pretty features. Behind the station he places a block of model dwellings for 36 families, while a range of neat shops and stables behind occupy the vacant part of the frontage of Praed-street.

Mr. Klein has not confined himself to the Company's property, and has covered over much of the open cuttings of the line.

The premium of 50 guineas for the Edgware-road Estate has been awarded to Mr. F. A. Klein, whose plans generally have been left to speak for themselves, without any report. He sends two designs; one retaining the present engine-sheds, and surrounding them with factories and shops, and the other with a large market replacing the sheds, and surrounded on three sides by shops, and fronting Mitcham-street on the other. This plan would appear entirely to cover up the railway in a manner we can hardly think desirable.

Mr. Bassett Keeling has left a large open space at the back, next Mitcham-street, and surrounds it on three sides with a block of buildings, with separate dwellings on the several floors, reached by open staircases; between this block and others fronting Chapel-street and Upper Lisson-street, he leaves an internal gated street as a courtyard, forming a playground for children of residents. Mr. Keeling has been more fortunate as regards the Farringdon-road Estate, the premium of 50 guineas for which he has carried off. This site being close to the station and near the seat of the wholesale pottery trade, he has suggested opportunely the erection of a pottery exchange. A centre hall, about 250ft. long, by 40ft. wide, is surrounded by warehouses, shops, pattern rooms, &c. On the basement plan are packing rooms for the pottery goods, in communication with the railway, which passes beneath the central hall. The scheme seems ingenious and practical, and it would bring a revenue, to the railway traffic in the shape of goods.

Mr. F. M. Godden sent also a clever and suggestive design, proposing baths upon a large scale. In an accompanying perspective his design, not a bad one, is well shown. The skyline is somewhat crude, and the chimneys seem forgotten; perhaps the smoke would be utilised.

Mr. T. C. Sorby has obtained the premium of 50 guineas for the Clerkenwell estate, besides that of Praed-street. Finding shops in the neighbourhood unneeded, but no houses to let, Mr. Sorby proposes to utilize the vacant sites with small and model dwellings of a modest description, which do not call for comment.

The 50 guinea premium for the design for laying out the King's Cross Estate has been awarded to Mr. A. M. Ridge, for an economical arrangement of shops and warehouses, and the morals of the neighbourhoood may not therefore be injured or its tastes enlightened by the music-hall which Mr. Klein would have introduced among them. The lives of passengers will also probably not be endangered by the arches without abutments, and turning round curves, as Mr. Elliott has suggested in his elevations.

The premium of 70 guineas for the Barbican Estate has been awarded to Messrs. Wilson and Aldwinckle, who have sent two designs, one carrying a proposed new roadway over the course of the line, and leaving an airhole on one side. In their alternative plan, with a road from the Barbican crossing it at right angles, and bending with too sharp a turn towards Red Cross-street, two larger spaces are left open above the railway cutting, in the centre of blocks of houses. The class of buildings proposed, shops and warehouses, do not call for remark.

The premium of 100 guineas for the Smithfield Estate has been awarded to Mr. F. A. Klein, of Cannon-street. For this important work this gentleman has sent alternative designs, differing mainly in the direction of the principal proposed street through the site. In the one case it has been brought so as to open immediately in front of the Farringdon-street Station, and in the other on the one side of its façade, so as to continue in a line with Cow-Cross-street, which passes the station on the city side. The ground being valuable, the shops and warehouses are placed as closely as possible upon it. Mr. Klein not having favoured us with any report to accompany the plans, the Company, we presume, must make their own calculation as to the outlay and returns; and we, for lack of time, must leave those of our readers who may inspect the drawings to do the same. In our opinion, in comparison with his competitors, Mr. Klein has fairly earned this, the largest premium offered by the Company, by his well-thought-out and practical designs.

Upon the whole, as we have said, we think the authors of the premiated drawings have fairly deserved their success; but it is obviously impossible for us to have given the consideration we could have wished to the immense mass of drawings that have been sent in response to the interesting invitation of the Metropolitan Railway Company. The entire number of competition designs is, we believe, not less than 300, and the pains bestowed

upon them, and the talent and thought they evince, is highly creditable. As our labours were not impeded by the number of other visitors—for the greater part of the time we had only the company of the civil policeman in charge—it would seem that the profession is not yet fully aware of the exhibition which is laid out for them and the public within a stone's throw of the Praed-street Station, in several unoccupied shops, Nos. 3, 5, 7, and 9, Craven-road. We strongly advise our readers to avail themselves of the opportunity for the inspection and study of these drawings thus afforded by the Metropolitan Railway Company.

THE MALADY OF MODERN ART.

WE are not about to write a lamentation on the decline and fall of architecture. We believe a portion of it, on the contrary, to be in a more hopeful state than any it has known for a century or more; but that the great bulk of it is still weak and sickly, still battling with the remains of chronic disease, those artists whose own work is the healthiest will be the last to deny. We wish at this time to notice the average of modern art, not the favourable exceptions — the buildings which rise around us on every hand, and the attempts of art workmanship which present themselves in every shop and show-room. Looking thus at the mass of what has been done recently, and is being done at this moment, it would be easy to make out a long list of failings. Such lists have often been made out. Criticism has been lavished—and by no means uselessly—on the separate points in which our ordinary architecture fails; but far greater good might be done if attention could be directed to the causes of these failures: if, instead of attacking merely the isolated symptoms, we could attack the common source and origin of them all. It is unfortunately too true that there are more sources than one; and it is not by counteracting a single morbid tendency that all unsoundness can be removed. Yet there is one tendency, so almost universal in the average work of the day, that it may be called pre-eminently the malady of modern art. It shows itself under the most opposite shapes; it is confined to no particular style; it is equally at home in Gothic, Classic, or vernacular. Unhappily, too, it has as yet no definite and easily recognizable name. Sometimes it is mildly described as "weakness of design," "crudeness," or "lack of unity;" but the essence of it in reality is in want of thoroughness and want of thought. The mind possessed by it never masters difficulties, but always tries to shuffle out of them. Such a mind loves plausibilities, and never goes to the bottom of anything. Its ambition is to keep knotty points out of sight, and make matters smooth on the surface. It never fairly grapples with its work, and subdues it from end to end. This is the one all-pervading vice of our would-be art; it sticks little bits of ornament over its work here and there and thinks that to be enough; it never so much as dreams of what is the very soul of real art—the conquest and mastery of each subject as a whole.

To take the most flagrant cases first: out of a hundred modern street buildings, how many are designed as buildings, and how many are treated as "fronts?" In how many of them does the "design" begin and end with the putting up of a single wall,—a mere screen before the real structure? The adjoining houses, one might have supposed, shut out enough of it; the architect would be glad to display all he could—to shew by the roofing, something of the general form, and to bring out the elevation against the sky by well studied chimneys or dormers. Nothing of the sort: it is much easier to hide blunders than to avoid them—to conceal an ill-designed roof than to invent a good one. A few feet of brickwork will cover it up and save the necessity for hours of thought. This is what passes for architecture in half our city shops and warehouses. If the effect is to be "plain and substantial," a few cement mouldings are run round the doors and windows: if it is to be grand and magnificent, the carver is called in to distribute over it so many yards run of his stock patterns. There is not even an attempt at making the building architectural: all that is desired is to conceal it by a plausible falsehood. But all our street buildings, it will be said, do not begin and end with a sham front. Numbers of them are visible all round, sides, and roof, and chimneys as well. Very true: but they shew in a different way the very same fault as the others. We are speaking throughout, it must be remembered, of average and ordinary works, not of exceptionally good ones: and we submit that in all types of them may be traced the same powerlessness to treat anyone of them as a whole. Grant that in the type now in question the walls and roof are visible; grant that the building is so far better than those in the previous group; that it, is in fact, no worse than a common barn or cowshed. This of course is higher praise than can be given to a large number of modern street buildings; but it is rather too low a qualification for the title of "architecture." And yet, as far as general design is concerned, most of the works in question have no other. As regard shape, outline, mass, light and shade, general effect, they might have been the work of a country mason, and by no means a clever one. They are probably mere brick boxes with roofs to them; or, if not, their parts seem to have come together anyhow; there is no order, no artistic arrangement—nothing of what painters call "composition," to be traced in them. Architecture, in the highest sense, is absent altogether. Some architectural details, it is true, are applied or missapplied, to make the thing pass for "a design;" but they are disconnected, jarring, inharmonius, unreal. It would have been better to have left matters as they were than to emphasize by contrast the absence of artistic power. "To hide with ornament the want of art" is a line which has been quoted till it has almost lost its force; but it exactly describes the process by which the inferior work of the day is made to pass muster with the public. They see wretched proportions, shapeless outlines, blunders, and vulgarities innumerable; and they are persuaded into thinking them all very fine by the addition of a little commonplace ornament. If we turn from building to its accessories, such for example as furniture, the case is just the same. The so-called "Gothic" designs are for the most part mere pieces of barbarism and awkwardness smothered in Gothic decoration to make them go down. But neither here nor elsewhere, in inferior work—which unhappily means at least nineteen-twentieths of the whole—can there be found any power to grasp and deal with general design and arrangement. There is no ability to bring things into order and shape, whether the things are large or small. If they are plain, they stand in uncompromising ugliness; if they are enriched, they show deformity set off by finery. The designer does not touch the things themselves; his decoration is a mere disguise; and this, above all others, is the malady of modern art.

VIOLLET LE DUC'S "DICTIONNAIRE RAISONNE DE L'ARCHITECTURE FRANCAISE."*

II.

THE first volume of M. Le Duc's dictionary contains 506 pages, embracing 45 articles, commencing with the word *abaque* (abacus) and terminating with that of *aronde* (dovetail), but one of these definitions occupies upwards of 160 pages of closely printed matter, and is illustrated with 165 engravings. This definition, to which we shall have to refer again, is an able essay on the history of French architecture during the period embraced by the author's researches, and is divided into that of religious, monastic, civil, and military architecture. In culling from the wealth placed before us, we shall, as a rule, avoid those definitions which are, or ought to be, well known to our readers, reserving our space for the more recondite or the more suggestive articles, and shall select those which more markedly bring out the principles set forth in M. le Duc's preface, and on which we commented in our last number. Among the first of these we would draw attention to that given under the head of *Application*, a word used to express applied ornament as distinctive from that decoration which is incorporated with and which forms a portion of the construction of an edifice. This definition embraces such arts as painting or gilding surfaces, the application of ornamental plaster-work, mosaics, or other purely decorative objects. In Greek architecture, the application of a thin coat of plaster to the surface of a building was a common treatment; the remains of Pompeii, the ruined temples at Agrigentum, exhibit this treatment as the general one; in fact, where the material was not in itself beautiful, fine, and smooth, the Greeks sought the aid of "application" to obtain those qualities they valued so highly. In Roman times thin slabs of rare and highly coloured marbles and porphyries covered the walls, a mode borrowed from and still retained in the East. Mosaics played a great rôle in Byzantine and later times; but these step back too far into antiquity to be specially commented upon by our author; and from the Carlovingian epoch up to the twelfth century the clergy of France were not rich enough to avail themselves of such luxuries. As they grew more wealthy, altar retables, tombs, and the other smaller objects necessary or accessory to churches began to receive applied ornament, and the feeling once generated or revived, the art of "application" spread till it covered the whole of the edifice. Suger decorated the rood-loft of the abbatical church of S. Denis with ornaments in bronze and figures in ivory; enamelled and silver-gilt plaques covered the altars and tombs, and, as coloured marbles were rare in the north, coloured glass did duty for them. Blue glass, mounted on silver foil, filled in the spandrels of the arcade of the Sainte Chapelle at Paris, having on its surface delicately-pencilled ornaments in gold—a process of ornamentation quite worthy of judicious revival, in spite of the rather crude restoration of the edifice referred to. At present its use seems to be restricted to the vulgarities of shop-fronts and gin-shops. Sometimes delicately-painted ornaments on vellum, rivalling the illumination on the margins of elaborated manuscripts, were used as the decoration of smaller objects, and protected by sheets of clear white glass; an application which might be of great use in the decoration of panels of doors and cabinets. But one of the most useful "applications" referred to is one which we have not seen revived, but which would be of great service in the decoration of small surfaces. "At the end of the twelfth century the application of impressed plaster-work to the surface of statues and smaller portions of internal architecture was frequent. These applications were composed of a very fine coat of lime, on which, whilst it was moist, delicate ornaments in low relief were stamped by means of wooden or iron tools," and which were afterwards painted and gilded. Nor was this mode of ornamentation confined entirely to internal use; often it was used in those deeply-recessed and shadow-loving porches which form the glory of the cathedrals and larger churches of France; and portions

* Dictionnaire raisonné de l'architecture Française du XI. au XVI. Siecle, par M. Viollet le Duc, architecte du Gouvernment, Inspecteur-général des Edifices Diocesains. 10 vols.; 8vo: Morel, Paris, 1854—1868.

of this species of decoration yet remain in those of Angers and Notre Dame at Paris. In the fifteenth century they endeavoured to substitute a resinous composition for the plaster coating, but without success; that has scaled off and disappeared, whilst the earlier process has endured. Traces of this species of decoration are not unfrequently found on the flat surfaces of walls, presenting the outlines of fleur-de-lis, sacred monograms, stars, and other simple ornaments, much in the same manner that the pargetting of our old half-timbered houses in many parts of England yet do; and it is worthy of seriously thinking about for the decoration of our large-walled and bold-looking churches and chapels—especially the latter. It has the merit of being cheap. Another species of application is also worthy of revival for cabinets and smaller articles of joinery, and is thus referred to by M. le Duc. "During the twelfth, thirteenth, and fourteenth centuries they also applied upon wood thin vellum, rendered flexible by being soaked in water, and fixed to the object to be covered by glue or cheese size. On this covering, which followed all the forms of the mouldings, they tooled other ornaments in faint relief; they combed it, gilt it, and attached to it pieces of glass painted on the under side." Many of the processes used in this species are described in the work of "Theophilus Presb. et Monac. Diversarum Artium Schedula," a work of which we should hail with pleasure a new translation, that of Hendric not only being difficult to procure, but also being very defective.

Those who are familiar with the richly and quaintly-tooled impressed vellum bindings of the fifteenth and sixteenth centuries will be able to form an idea of the richness of effect thus obtained by simple means; and the study of the class of ornament then used for this purpose will amply repay the student. Medallions of sacred or historical subjects are frequent, and the judicious mixture of plain tooled lines with reticulated or flowing ornament is very suggestive. Boiled leather was frequently used for coarser works, and the application of these decorative processes might most advantageously be revived.

Our next extract is of a more scientific and architectural character, and from the able definition of the word *arc-boutant* (flying buttress) we shall borrow largely.

M. le Duc rightly esteems the adoption of the flying buttress as one of the chief structural inventions of the middle ages; it liberated its architects, it converted the art of building into a science, but it ultimately, as all surplus of science does, killed architecture as a fine art. When architects became pre-eminently engineers, architecture as a fine art perished. They wrought miracles and ceased to appeal to human feelings—they no longer expressed human ideas—they either rose to be almost gods in making something out of almost nothing, or they descended to the other pole and frightened us with scientific atrocities—buildings constructed with the wisdom of the serpent, no doubt, but which, certainly, if the devils beheld they would tremble. Man liked them not, and then the architects changed their tactics; flying buttresses were abandoned; and human nature, seeking for a visible expression of support, reverted to the primitive ideas of Classic architecture. Of course, M. le Duc looks only at the bright side of flying buttresses—he sees only the use of them; of the abuse, if he is conscious of it, he says but little. We feel we are dealing with a partisan, but his pleading, or rather his reasoning, is so exquisite it needs the utmost catholicity in art to avoid being pledged to the view his enthusiasm carries us into. "According to the taste of each school, men have greatly praised or greatly blamed the system of flying buttresses," he says, on page 60. "We do not undertake either to defend them or to show forth their faults; there is but one thing for us to say: according to our view of this system of construction, it is that this is the frankest and most energetic means adopted by the builders of Mediæval times. Up to this time they were groping in the dark; from the moment when this system was adopted, ecclesiastical architecture developed itself: it marched boldly on the new pathway. To ask for a Gothic church without flying buttresses is to ask for a ship without a keel; it is for the church as for the ship, a question of 'To be, or not to be?' The problem that the architects of the Norman epoch set themselves to solve was to crown with a vault the Latin basilica. So far as regards the disposition of its plan, the ancient basilica completely satisfied the requirements of the Latin church; it had wide open spaces, small supports, air and light. But the ancient basilica was covered with a timber roof—the absis alone was vaulted. Now, in our climate, these roofs were neither wind nor water-tight; they rapidly decayed when there were no metal spoutings—things which can only exist in the midst of a people skilled in metallurgy. Moreover, wooden roofs burnt, and a building covered only by a wooden roof, once burnt, was destroyed from top to bottom. Up to the tenth and eleventh centuries our histories unquestionably record that burnt churches necessitated new ones. The chief thought of the clergy in those days, and consequently of architects also who built new churches, was to vault the nave. But the walls of a basilica, supported on slender columns, did not present sufficient resistance. In the eleventh century the builders in the centre of France had given up clerestories; they resisted the thrust of the barrel vaulting of their high naves either by quadrant vaults, as in the Auvergnat churches, or by small intercepting arches springing from the aisles. Thus the naves could not be lighted by windows; the aisles were almost as high as the nave, and the broad external walls, strengthened by buttresses, resisted the combined thrust of both larger and smaller vaults. In the north of France this system could not prevail; the large centres of population demanded large churches; they had need of light; it was necessary to obtain this light by means of windows pierced in the nave walls, and consequently they had to overcome the resistance afforded by the vaulting of the aisles." "It required two centuries of groping, of attempts frequently futile, to arrive at the solution of this simple problem;" "but when once this way was opened, progress was rapid for the flying buttress, which was born in the eleventh century, reached its culminating point and declined in the fourteenth." "Amongst the most ancient of these flying buttresses is that of S. Remy, at Reims, the construction of which belongs to the latter half of the twelfth century (see Fig. 50, p. 62). Here this feature is simple; it abuts directly against the point of thrust of the vaulting, and extends its resistance in a vertical line by means of an external column detached from the wall above the triforium." By and by the builders of those days found out that this was not enough. They found out that the thrust of pointed arches of wide span was not restricted to a mathematical point; that the wall had a tendency to buckle, owing to the divergence in the line of thrust created by the sliding of the voussiors of the arch upon each other; and to counteract this they doubled the arch of the flying buttress, allowing the lower one to impinge below, and the upper one above the exact thrust point, uniting them by a solid mass of masonry. An early example of this expedient is illustrated by a sketch of the flying buttresses which support the vaulting of the apse of the cathedral of Soissons (illustration, Fig. 52, p. 63), the construction of which goes back to the early part of the twelfth century. The heads of these abutting arches rest against counterforts, supported by engaged columns." "It is necessary to observe that the last voussoir of each arch is not engaged in this masonry, but remains free to slide in case of settlement, illustrating the application of that principle of elasticity on which the stability of these vast buildings depends. The faculty of sliding thus given to flying buttresses prevents their crippling, for it is unnecessary to say that they would be useless unless their thrusting force remained intact, which would not be the case if the arch was crippled. For example (in the diagram 53, p. 64), let A B C be a flying buttress; if the vertical wall D settles at all, it must needs be that the arch would be broken as B, as in Fig. 1, if its head were engaged as A. If, on the other hand, a settlement occurs in the buttress E, the arch of the flying buttress would be broken at the same point, in the manner shown by Fig. 2. It is easy, therefore, to understand how necessary it is to leave the arch free at A, in order to allow of it preserving its curve intact and accommodating itself to these circumstances. These precautions in the jointing of flying buttresses were not always taken, and the proof that they were not useless is found in the fact that when they have been over looked disastrous results have nearly always ensued." These arches, as we have before stated, were generally doubled, and in the early half of the thirteenth century attempts were made to unite the two—attempts resulting in much beauty, but which appear to have been abandonned. Probably homogeneity destroyed elasticity. We have a very fine and suggestive example of this treatment presented to us from the choir of the Cathedral of Amiens, where the weight of the unusally massive vaulting necessitated an unusual degree of resistance. The vaulting there is about 16in. thick; the materials are heavy, rough and compact; consequently the architecture is more massive and less delicate than is usual with that of the thirteenth century.

Vaults of nearly 50ft. span, constructed of such materials as these, exert an enormous thrust, and it is worth while to examine how the architects of those days resisted and balanced them. If you turn to our illustration, Chartres, you will there see a sketch of the flying buttress, with a detail of a portion of it, as the vault was heavy, so are they; massive wall-buttresses receive the arches, which are ingeniously coupled by a radiating arcade; each course is radially jointed, forming a separate arch of itself, and the whole offers an oblique resistance to an oblique thrust. Again, the upper portion of the buttress is connected to a channel for the water from the roofs, the upper column shewn on the sketch forming a down-spout to the main roof, and it is thus conveyed to the gutters of the aisles, relieving the nave walls from the splashing occasioned by discharging the water from the usual gurgoyles on to the roof of the aisles, thus tending materially to the conservation of the building. This coupling together of the arches is, as we have already said, somewhat rare; but the union of the arch, with its upper raking line of water channel, is of common occurrence. Examples of this mode of treatment are given in Fig. 62, p. 72, from the same cathedral; but of some 30 years' later date, when the single arch is connected with the nave-way by a pierced and traceried arcade. It will also here be remarked how the early system of spreading the lateral thrust, virtually increasing the thickness of the main wall by means of an isolated column on the triforium wall, is retained, and how much economy of material and relief from the undue pressure of weights imposed upon the main supporting columns is thus afforded. From this time, the system here inangurated prevailed, and a good typical specimen of the mode in vogue up to the later period of this species of construction will be found in Fig. 69, p. 79, taken from the church of Saint Wulfrund, at Abbeville. Science here out-did itself; art had declined, and the too-elaborate balance of resisting forces destroyed the means adopted. The endeavour to gain still further lateral resistance overshot its mark. The hindrance of the

sliding motion at the point A led to grave disruption of the arches, for once broken at this point the function of the arch was transferred to the straight line of the water channel. When flying buttresses were constructed on this principle the thrust of the main vaulting was brought to bear on the line C D, and thence transferred vertically to the arch A, augmenting the duty imposed on it of carrying the dead weight of the water channel. This causes a counter thrust from the arch A B, which, meeting with no resistance at D, the thrust of the main vaulting arch having already been conveyed away, the wall becomes crippled in this point, and the flying buttress becomes no longer a means of support, but an implement of destruction. Often and often do we see in England wonderfully misconstructed flying buttresses, merely made to win a competition and look pretty; and we would urge on all who can do so, to carefully study the elaborate treatise we have thus skimmed. To those who cannot read this we advise them to abstain from the use of this double-edged sword until they can. Flying buttresses are of two sorts, useful and useless; but the useless are not simply so, they are an element of destruction—an enemy who never sleeps. M. le Duc enters learnedly and reasonably into the appropriate line of curve their arches should take, and gives to this important subject the full consideration it demands; but our space prevents our giving a fuller demonstration of his analytical reasoning.

ON THE HISTORICAL DEVELOPMENT OF ORNAMENTAL ART.

THE twenty-second lecture of his course on the above subject was delivered by Dr. G. G. Zerffi, in the Lecture Theatre, South Kensington Museum, on Tuesday afternoon last. The lecturer commenced by observing that though the Indians, the Persians, the Egyptian priests, the Greeks, the Etruscans, and the Romans had all been members of the Ayrian group of mankind, nothing could have been more different than their religions, social, and artistic conditions. Many analogies could, however, he continued, be traced, and the farther we went back into history the more striking did these analogies become, all tending to prove a common origin. It would suffice for our purpose never to lose sight of the fact that the ornamental forms common to all these nations had not always been mere copies, but were preserved echoes of past ages, and had varied with the geographical position of the people, and their social condition. Referring to the illustrations of Roman art before him, he said that we found in them nothing but Greek motives. The Greeks remained the distinct representatives of individual freedom, on the basis of a democratic state-form; the East represented despotism in religious and social matters, and Rome would show us these two principles in everlasting conflict. The very geographical position of the city had necessitated the use of force to sustain its influence, and the element of force had become the exclusive basis of the Roman world. From the commencement of her self-created independence, Rome had adopted not the dynamic force of creating, but that of acquiring what others possessed. The arrangement of her temples, houses, bridges, and aqueducts had been Etruscan, her ornamentation Greek, and her architecture Egypto-Asiatic. The same influences had given her her mythology and heroic myths. Whilst the Etruscans had been concentrating their artistic powers on small articles, and the Greeks had ceased to do more than preserve their artistic traditions for the benefit of their new task-masters the Romans, those Romans themselves had excelled in grand and powerful undertakings, always having before them the purpose of glorifying the expanding and conquering force. They had erected gorgeous temples, not proclaiming the glory of the divinities to whom they were consecrated, but testifying to the powers of the constructors. Their edifices had been pompous, not constructed in accordance with the laws of beauty, proportion, and correct ornamentation, but profusely decorated to exhibit the wealth of the owners. Even this love of grand appearances, which seemed so entirely Roman, had been inherited from the immortal Greeks. The Macedonians, once masters of Asia, had commenced not only to found but to construct cities on a most gigantic scale. Pergamos, Sardes, and Harlikarnassos had been built under the Greeks. At Alexandria, under the supervision of Dinokrates, the court architect of Alexander the Great, Egyptian dimensions had served as a basis for gigantic constructions. Serapeons (temples with ample outer buildings, symbolical of the power of Greece over Egypt), museums, gymnasia, baths, &c., had been built on Eyptian plans. This Græco-Asiatic tendency had been transmitted to the Romans, a young and ambitious people possessing the power of carrying out Alexander the Great's Titanic idea of subjugating, and at the same time civilising, the whole world. The Romans might be said to have remained faithful to Indo-Germanic traditions, and had succeeded in creating, if not an original, at least an imposing architecture. The three principal political phases of their national life were clearly to be traced in the varying decorative styles of their works of art. During the first period both architecture and sculpture had been wholly neglected, the powers of the nation having been directed towards the establishment of an independent state existence, and consequently few Romans had devoted themselves to art. According to Plutarch the representation of divinities in human forms had been prohibited by Numa Pompilius (714 B.C.), and sculpture had not flourished until 160 years after his reign. From Varro we learnt that though certain statues produced by Etruscan artists existed, yet there were neither statues nor images of the gods in the temples. Under Tarquinius Priscus a statue of Jupiter, made of terra-cotta, had been erected, and a quadriga of the same material had been placed on the top of the temple. An article of a treaty, concluded by Porsena, after the expulsion of the Tarquins and the establishment of the republic, stipulated that iron should henceforth be used for ploughshares only, thus proving that this metal had been known. Art had laboured under great restrictions; at first the highest honour granted to a distinguished citizen was a pillar with an inscription; later, a statue in bronze not more than 3ft. in height, was granted for exceptional merit. A statue of Horatius Cocles, one of Cloelia on horseback, erected in the temple of Vulcanus, and many others, were said to have been in existence in the times of Seneca, but public acts had still been inscribed on simple bronze columns. The first temples and statues must have been of small dimensions, as the temple of Fortuna had been constructed in one year. Notwithstanding the never-ceasing wars, the fine arts had not been neglected by the Romans, but they had merely been employed to present some visible signs of the heroic deeds of the Consuls and their soldiers to the masses. By this means they inspired the people with pride, self-glorification, and a sense of exclusive patriotism instead of a love of beauty. After the destruction of Corinth and Carthage, and the close of the third Punic war (145 B.C.) security having become established, and great wealth acquired, a greater love of art followed. The buildings in the earlier days of the Republic had all been highly practical. The strong walls had been constructed of large squares of stone, and bridges, aqueducts, and cloacas had been the principle public works. We had, said the lecturer, traced the arch in India, and seen vestiges of it in Persia and Greece; we should now find that with the Romans it had become the expression of an interrupted, or rather perforated wall. The arch, as perforation of a wall, had nothing to do with the idea of supporting the roof, but was an ornament of the wall. Together with the arch, the column with its epistyle (or architrave) had been used to supply a support to the roof. Arcades might be assumed to be as old as the arch; and when we saw these principles revived in Italy, we should not have to deal with an innovation for mere decorative purposes, but should find that the combination referred to was rational and the outgrowth of the very nature of the fundamental principle the mixture of arch and columns. These happy combinations of pillar and epistyle, of arch and column, had enabled the Romans to construct their immense buildings, and in doing this they had given us a correct view of their national character. They had looked upon society as the outgrowth of abstract principles. The individual had been lost in the generality, and was valued in proportion to the property he possessed. To increase his property had been the aim of every Roman. Joyous freedom of intellect was unknown, and the cultivation of the imagination was considered as superfluous. With the Romans even religion, the mother of the arts, had been looked upon as a means for holding the masses in subjection and obedience. To blind the people, and force them to submission, pompous games had been instituted, triumphal processions held, and colossal temples and other edifices constructed. Every column, every pillar, each stone and carving, each console and cornice, every niche and every statue proclaimed Roman ambition, vanity, and national pride. Passing now to the different periods of Roman art, the lecturer said that the first extended from the conquest of Corinth to the accession of Augustus; the second during the rule of the Julians and Flavians (96 A.D.); the third from Nerva to the thirty tyrants (96-260 A.D.); and the fourth from the thirty tyrants to the foundation of the Byzantine empire. During the first period we should find Rome had been the abode of Greek artists. Art had been taught and treated theoretically and practically. The wealthy and powerful had affected a kind of enthusiasm for art, and delighted in luxury. The walls had been white, with painted ornamentations in red: this led to the use of genuine red-coloured bricks, mixed with others, and had originated polylithic wall-decoration. Marble had also been used, and the houses became more and more decorated. A party opposed to this tendency had arisen, and the conflict between the *intelligentes* and *idiwtaig* commenced. During the second period the emperors had endeavoured to amuse the masses. Art had soared high above the rules of simplicity and truth, but was still full of admirable motives. Composite columns of gorgeous patterns; consoles of powerful mouldings; archivolts and architraves profusely decorated; the acanthus and olive-leaf; scrolls of high finish, and gigantic dimensions in general had distinguished this time. During the third period the provinces had begun to show signs of vitality, and under Hadrian Greece had once more produced great works. The power of the state, however, had been broken. No people could tolerate tyrants like a Commodus without being punished. Religion had stepped in—not the pure religion of love which would at another period present itself for consideration, but the superstitious religion of the East. The worship of Isis and of Mithras—a mixture of Egyptian, Assyrian, and Persian mystic doctrines had been introduced; the Chaldæan Genethlialogy, or art of divining the future from the stars at the birth of a person; magic amulets; and the Theurgic philosophy had given the death-blow to Greek and Roman art. The artistic object had received its value from superstition and not from its intrinsic beauty. Beauty, on the contrary, had been considered detrimental to the use of symbolic signs. It was said that the gods would no longer shower down their gifts if beautiful decoration was employed, because the advocates of mysticism found it less troublesome and less difficult to deceive with mere amulets. Thus had been ushered in the fourth period. During this we should see the ancient world vanish. Art had invariably left humanity when spirit and matter had been looked upon as antagonistic elements in creation, the one being good and the other evil. Formality became ascendant, and faith a means for mystic doctrines. Metaphysical symbolism had ruled supreme, and extinguished every spark of real artistic sentiment, thus burying the intellectual faculties under an oppressive tumulus of superstition, and checking real moral development.

The four periods, with their details in architecture and sculpture, will form the subject of the next two lectures.

CHURCH OF S. LUBENTIUS AT DIETKIRCHEN.

THE Church of S. Lubentius is situated on the Lahn, an affluent of the Rhine, in the Prussian province of Nassau, between Ems and Wetzler. Built in the eleventh century, the church has well preserved its original form, The exterior is very picturesque, the building being erected on the summit of a high rock. The material is a very hard stone, much used in buildings of this province and age.

Paul Tornow.

The Battersea Vestry has authorised the payment of £652 to Mr. Edward Ryde, the eminent surveyor, for professional services rendered in valuing the railway, gas, and water companies' and other hereditaments within the parish, for the purposes of valuation, prepared under the provisions of the Valuation of Property (Metropolis) Act, 32 & 33 Vic., c. 67.

HIGH ART AND DR. DRESSER.

"DU SUBLIME AU RIDICULE" there is often only one step—and that a very small one. According to a paper read before the Society of Arts on February 8th last, by Dr. Dresser, on "Ornamentation considered as High Art," the discussion which followed, and the letters which followed both paper and discussion, we really must say that Dr. Dresser has perfectly succeeded in bringing prominently—nay, artistically—the fact before our eyes that any man may be "sublimely ridiculous." Ornamentation, according to our new paradoxical prophet, is high art; but sculpture, painting (or, as he calls it, "pictorial fine art") is a mere falsehood—a lie, with which the "Most High" has nothing to do. The proposition put forward by Dr. Dresser is not new. He is an ornamentist, makes money as such, and naturally thinks that everybody ought to become a believing follower of his faith in ornamentation as a high art. We have no objection to this kind of one-sided enthusiasm. Let the shoe-black be proud and conscious that without well-cleaned boots there is no salvation of the soul; for "cleanliness is next to godliness." Let the baker be proud of the loaf he so artistically turns out, and be convinced that without bread no sciences and arts; for "bread is the staff of life." Let every individual, of whatever branch of art he is, think himself the very centre-point of gravitation of our globe, which, if disturbed by a hair's breadth, would bring destruction on the whole universe; but let him beware of ventilating his little individual pride in the tatters of an apparently scientific garb before some artistic society. The pride then becomes obnoxious. The ventilation may rouse a terrible storm. It is an old Latin saying, "*figulus figulum odit*"—in free translation, "pots and pans often quarrel with one another." Dr. Dresser has done immense good with his paper. He has not convinced anybody that a painter is nothing but a liar, but he has given us an opportunity of judging how much may be talked on a special branch of decorative art, and what letters full of abuse may be written by one "figulus" against the other without in the least promoting a correct view on art. On the contrary, he gives up art again as a bone of contention to the practical and theoretical opponents. Between these two strong-headed parties art is dragged to the right or to the left, torn to pieces, either over-fed with practical work, or starved to death with mere theories. In both instances the lot of our art is not to be envied. Dr. Dresser appears to personate the "theoretical talker," as a correspondent has it, who, on the other side, represents the "practical artist," Now, it so happens that the paper read, the discussion which followed, and the letters which it provoked, prove an incredible amount of confusion of ideas and want of correct knowledge on both sides. Those who accuse Dr. Dresser of being a theorist prove that they do not know what the word "theory" means; and those who pretend to be all for mere "work and labour done" are not aware that they are hypothetical theorists. For the very assertion, that an artist has not to know, but only to work, is a mere hypothesis, the efficacy of which has to be proved by those very men who hold all theoretical knowledge on art in abhorrence. Dr. Dresser, in his paper, expresses opinions — hypothetical opinions—and beyond the assertion of these hypotheses in a very strong dogmatic form, he does not go. His definitions of art are not quite clear. When he asks himself, "What is art"? he begins his definition with a very suspicious subjunctive, and stammers, "It *may* be said to be the disposition or modification of things [what *things*?] by human skill [what skill?] or taste [what taste?] in a manner which secures [how so?] the awakening of pleasurable or desirable emotions [then anybody scratching his head is an artist] of the passions, intellect, or soul [is there intellect without a soul, or is intellect not soul and what is soul?] of those to whom the art addresses itself." Apelles said to the shoemaker, talking of anything else but boots, "*ne sutor ultra crepidam*;" in free translation, "do not be a philosopher unless you know the meaning of words." What does this sentence mean? "High art *may* [again the hypothetical subjunctive] be said to be an instructive hieroglyph of beauty." What is a hieroglyph of beauty? Perhaps a white negro? Does it stand so low with our knowledge of art that when members of the Society of Arts come together in the nineteenth century, an ornamentist is allowed to proffer such a jingle of words. But he does not stop there; he goes on and says,—"It [high art] is symbolized imagination or emotion, such as is calculated to teach some moral lesson or impress some important truth." What is a symbolized emotion? If we have a misfortune and we record it in our diary by two strokes crossing one another—then we have produced a work of art—for we have symbolized an emotion. If we ornament a vegetable dish with a wreath of ivy, we teach a moral lesson and an important truth; vegetables pass away, but ivy is evergreen, and the glories of heaven are everlasting! Shall we never learn to leave our canting propensities behind us when we enter the temple of the Muses? What does Dr. Dresser mean when he states that in ornamenting carpets, lamps, bowls, wall-papers, he teaches us moral lessons? What moral lessons? The moral lesson to go and learn from Dr. Dresser how to ornament—for he gives us some important truths into the bargain; he is not only ornamentist but missionary too. His frets, his meanders, his arabesques, his guilloches, are so many homilies, so many collects. Yes, collects of pounds shillings, and pence. Why does Dr. Dresser use big words like a quack doctor, praising his trade as the only moral, artistic occupation of the world? The ornamentist is an artist; who denies that? but there is no need for a teacher of ornamental and decorative art to talk unintelligible phrases, and to abuse all other branches of real high art. We do not care for mere opinions on what is high or low art, whatever that means. We know that our art does not bear comparison with that of other countries in Europe, because we make art subservient to other purposes. Art, as *art*, has nearly vanished from us. Art has been with us either the handmaid of a religious sect or a political party, or some crotchety practitioner, to whose paradoxes a quantity of unthinking, weak-minded disciples swear. In politics we have our "leaders:" they save us the trouble of thinking; in religion we have our sects; they help us to look respectable; and in art we have our paradoxes—because they pay; they go down with the ignorant. When a man uses in an artistic society the expression "that he detests an imitative work as an attempt at a lie," he forgets the origin of his own decorative art, which is nothing but an imitative work. Does Dr. Dresser mean to say that decorative art is not founded with all its patterns on nature? Does he not know that before ever a savage began to ornament, every possible pattern of ornamentation was made by Nature on shells, leaves, flowers, wings of butterflies, &c., and that his finite brain never will come up to the variety and beauty of the Infinite Artist, who, through His immutable law of affinity, has created finer geometrical figures in snow-flakes than any decorator of flats or rounds will ever be capable of inventing; and that his geometrical inventions and combinations of pretty little religious tracts in lines are nothing but poor, very poor, imitations of crystallization in matter! That when he calls the pictorial artist a liar he is condemning himself. The difference is only that the sculptor and painter imitate the very highest products of the Creator, whilst the ornamentist imitates the very lowest forms—the winding creepers, the wriggling worms, the meaningless twistings of straight and crooked lines. If we admit that geometrical forms taken from bodies only may be used artistically, why should we deny that the organic products of Nature may be used to ennoble our nature, "to set forth some moral lesson in harmonious shapes and colours?" Are not the pictures of a Hogarth full of moral lessons, more impressive than any Mahomedan or Dresserian arabesques? Schorn defines arabesques "as a kind of painting using natural forms in phantastic dispositions and combinations to express symbolically some allegory." We have here an authority, and his definition of decorative ornamentation in arabesques put into plain words would come to this: the ornamentist says one thing and means another, that is symbolism; and then again, he means one thing and says another, that is allegory. Now in essence both these things are much worse than imitation—they are deceptions in the very highest degree. We know from history that allegories and symbols have retarded real science and art more than anything else. Symbolism is the wide cloak under which deception, falsehood, prejudice, hypocrisy, and stupidity may hide. Allegories are apt to be taken for truths, and another kind of deception is practised. But there is no harm in art deceiving us. If Dr. Dresser's hypothesis would hold good, then, the "Arabian Nights," with their allegorical undercurrent of meaning would stand much higher in poetic value than the works of Æschylus or Shakespeare, for these latter painted men with their passions and shortcomings; both imitated characters as having spoken or acted so and so; in fact, both have been "liars!" We wish we had plenty such liars; we could well do without the ornamentists giving us moral lessons on a piece of carpet "setting our minds towards Mecca or Jerusalem, or some other sacred city of our spiritual Lord and King!" The paper of Dr. Dresser is a curious sign of our times. Where is our place in art-knowledge that such a paper could be read and discussed; and how has it been discussed? One single member, Mr. Burchett, spoke with dignity and thorough knowledge of the different theories of art. An honest champion, he broke a lance in honour of the genius of Phidias, Canova, Michel Angelo, Titian, and threw his antagonist with the spear of his cutting logic clean on the sand of the arena. Mr. G. A. Sala spoke like a newspaper writer accustomed to write on a horse-show one day, on a concert at the Crystal Palace with 3,000 performers the next, and on a secret treaty between Russia and Germany on the third; he was very eloquent, but said nothing. Mr. Edward Hall kindly condescended to plead for Moorish and Arab patterns on walls and carpets, but did not altogether object to a frieze being decorated like that of the Parthenon. We are grateful for this opinion, only we should like to be furnished with artists who could make a frieze like that of the Parthenon. Mr. Hyde Clarke, with a keen eye to business, advises us, "particularly at a time like the present when we are contending for the trade of the world, and when, from certain circumstances, there seemed a probability of England acquiring a greater share of foreign commerce than she had ever enjoyed before, to communicate some mental expression to the common products of the country." Where is this mental expression to come from? Not from abuses of real art and from a questionable praising of ornamental art as a product of symbolic teaching of moral lesson taken from the inner consciousness of the artist; not by setting up a new creed with the device:—"God is God, and Dresser his ornamentist;" but only by an honest and diligent study of the production of all the branches of art, with an honest and humble piety, and with a deep veneration for the intellectual power with which the Creator has endowed us to reproduce his creations in

wood, ivory, clay, bronze, marble, rounds, or on flats. The historical painter who immortalises scenes of the life of Christ, or of Greek, English, German, or French history, is not a liar. He uses, instead of geometrical lines or bunches of flowers, human forms, and speaks through these forms to our minds. Instead of propounding false and childish hypotheses, it will be well for our artists to study the slow and gradual progress of art in past ages. This study will furnish them with ideas, and enable them correctly to appreciate their own talents or their shortcomings. As to the letters called forth by Dr. Dresser's paper, we will deal only with two. A Mr. Wallace writes from the Linoleum Works, Staines, and argues against "Mr. Teacher" as an "unpractised theorist," because the public prefer wares that are more ornamented to their taste." This is altogether a libel on the English public. Firms like Jackson & Graham, and others, employ excellent designers, order new patterns, and sell them. It is the sluggish lower class of traders, who have learnt nothing, and do not want to know anything, that force their old cheap patterns on the market, and accuse the public of bad taste. Teachers of the stamp of Dr. Dresser pander to this tendency. They preach: "Have nothing to do with real art. Look at me, I am *the* high art; I do not sell my canvass painted over with groups of men who are no men, but mere lies, at so much gold per inch: I draw you a few flowers interwoven with delicious ideas on the immortality of the soul, the knowledge of good and evil, of mutual love and forbearance, &c. I follow out to the letter the old Jewish command—I make no graven images. I keep to the 'flat' in thoughts, words, and deeds." It is this kind of Puritan abhorrence of the flesh and blood and spirit in art, which deadens it, and which must be counteracted in schools and out of schools. We will now mention Mr. Moody's letter, divided into ten sacred commands. This writer hurls stones and bricks of abuse at Dr. Dresser's head. What a rage, what an unartistic way of controversy. Now Mr. Moody is against all talkers on art; he is all for work and labour done. But this is against the grand politico-economical principle which has made England one of the richest countries of the world. We mean the principle of "division of labour." The practical artist who has no time for the study of past works, of abstract theories of art-criticism, the culture of his mind, the enlargement of his views, the feeding of his imagination, who has always to draw on his own inner man, must have somebody else to read and study for him, to make him acquainted with certain laws and principles of symmetry and proportion, to guide his thoughts, to furnish him with intellectual food. This contempt and neglect of the higher intellectual part of art education has laid our modern art in England so low. Look at the writings of Flaxman, Sir Joshua Reynolds, Sir Charles Eastlake,—all men who cultivated their minds as well as their technical skill; they studied theories and works of past ages; they were real artists, and produced real works of art. The art-critic, the teacher of the æsthetical and historical branches of art, is one thing, the practical teacher of designs another. The one ministers to the mind and the imagination, the other developes the technical perfection in the student. Had Dr. Dresser enjoyed a systematic art education he never could have propounded his opinion. Had Mr. Moody had the same advantage he would not have said that theory is all nonsense; for the *one* Winckelmann has done more for the revival a real art in Germany than all her practical artists taken together,—and Germany is not badly off for artists. Let every one do on his own field the best he can, and let us, above all avoid the undue exaltation of one branch of art over others; for all trades and all arts, and all sciences honestly pursued, serve to promote our general improvement. In the replies to his antagonists, Dr. Dresser proves clearly that he suffers from a sad haziness of ideas with reference to his own hypotheses. He comes out very strongly as the mystic advocate of works of art "which embody the greatest amount of mind, or thought, or intellect, and are the best or most noble." Now the real painter works so entirely with his intellectual power that in order to express this graphically, Lessing makes his Conti, (the painter) say,—"Raphael would have been a great painter, even had he been born without hands." For it is not the colour of the paint-brush, but the intellectual power that flows through the paintbrush in pigments on the canvass which makes the painter. But Dr. Dresser stops his opponents short, and tells them "You have not the *grace* to understand my symbolic language as little as I, not knowing Hebrew, can understand the beauty of a Hebrew poem." First, art is not written in Hebrew; and, secondly, an art that is unintelligible is no art. Take a kaleidoscope, and shake it, and forms without end present themselves to your eyes; and according to Dr. Dresser's hypothesis you hold the greatest artist in your hands, created by Dr. Brewster, to teach us moral lessons. In passing in review of theoretical teachers who did no good at the South Kensington School of Arts, he mentions Dr. Semper as a French refugee. If Dr. Dresser's knowledge on art is as correct as this assertion, the sooner he begins his course of studies anew the better. Dr. Semper is one of the greatest living German practical ornamentists and architects, who, born at Hamburg, educated at Munich, visited France, Italy, Greece, and built the Theatre of Dresden, which was burnt down a few years ago, and is entrusted with the re-building of it. Dr. Semper has written many a valuable and really philosophical book on art, the study of any of which would have enabled Dr. Dresser to talk sense on art with that moderation and general grasp of details which distinguish the theorist from the parodoxical talker. What would Dr. Dresser say to a man asserting that only *bass* notes were music, that all melodies were lies, that *bass* notes alone formed the *basis* of music, and taught us to recognise the infinite in the finite, and made us see the square of goodness in the circle of our inner consciousness? X.

ALBERT DURER.

OUR illustration this week from the works of Albert Dürer, is one of the woodcuts of the life of the Blessed Virgin. It represents Our Lord taking leave of his mother before his crucifixion. The mother, in her anguish, supported by her faithful friends, two of the other Marys probably, has sunk to the ground while she listens to the last words of her Divine Son, who stands in sad dignity in front of the picture, blessing her before parting. As usual, the background is filled with a beautiful landscape, with a fortified town on the left, the drawing and details of which are admirable.

The *Northampton Mercury*, in some complimentary observations it offered on the appearance of the A. Dürer engraving, which appeared a few weeks since, stated that our photo-litho exhibited a certain rottenness which did not characterise the original. This was a mistake. The original was reproduced in the same size to a nicety, even to the smallest dot. Our illustration was *exactly* as it was executed and given to the world by the great master. The orginal, after four hundred years of exposure and wear, was soiled and spotty, whilst the copy, which contained every particle of the artist's work, was as clean and bright as the original when first printed.

From some letters we have received, it is evident that some of our readers do not appreciate the value of those reproductions. It is well, however, that they should know that most of Albert Dürer's engravings are literally worth their weight in gold. We are giving about their weight in silver, even for the *loan* of some of them, and we could not get them at that price if we did not guarantee this, that they should be returned harmless. No preceding age has possessed the ability to produce *fac simile* representations of works of art, and no professional journal but the Building News is enabled to do so now. Still, if we thought that a fair proportion of our readers would prefer illustrations of buildings to occasional reproductions of A. Dürer's works, we would comply with their request.

VICTORIA-TERRACE, ABERYSTWITH.

THE terrace some of the end houses of which are shown in our accompanying illustration, has been designed for the Corporation of Aberystwith by Mr. Seddon, architect. The site is at the extreme north end of the Parade, facing the sea, beyond and adjoining the Queen's Hotel, which was built a few years ago from the design of Mr. C. F. Hayward, architect.

The terrace will consist of about twenty-five houses, and reach from the aforesaid hotel nearly to the promontory which, projecting into the sea, terminates the Aberystwith bay to the north. Of these, three houses have been erected by Mr Thomas William, builder and lessee, and will be completed for occupation during the present season. That which forms the angle-house—seen in our view—consists of six stories in height, and those next it of five stories. With the object of providing suitable accommodation for families resorting to this favourite seaside place during the season, the plans have been arranged so that each floor may be complete in itself, with sitting, bed, and dressing-rooms, and every convenience.

The principal feature in the terrace is one that cannot well be adequately represented by an engraving—namely, the colour, which has been considered with the view of affording contrast and variety with reference to the existing buildings of the sea-front of the town. The frontage of Aberystwith towards the sea is very limited, and the greater part occupied by a monotonous row of mediocre houses covered with drab-washed cement, with Mr. Hayward's stately pile of the Queen's Hotel at the north end, executed in the purplish local stone, relieved by freestone dressings; beyond rises a noble range of green turf-covered mountains, scarred by stone quarries of the above-named hue. Mr. Seddon has, therefore, chosen as the material to build his houses up as high as the second story below the roofs in each case a bright rich red brick, from Cardiff, with freestone and light brick dressings to the openings, and black Staffordshire bricks used as a relief in the shape of bands and occasional diapers upon this red ground. But the uppermost stories and chimney stacks are in buff brickwork, with red ornamentation. The window openings are divided by columns of blue and green sandstones, about 9in. in diameter, with molded bases and zones and capitals carved in a simple manner. The roof of the angle-house is carried up as a steep pavilion, with a lofty stack of chimneys rising from its centre. Large dormers, bay windows, and corbelled porches give diversity of treatment to the smaller houses.

A fine esplanade has recently been formed by the Corporation, at an expense of about £2,000, in front of the whole of the site of this terrace, with several circular bastions projecting towards the sea.

As an approximate estimate of the cost of the houses, £2,000 may be named for the end ones, and £1,600 for the others, but there are exceptional advantages belonging to the site, as a quarry is situated immediately behind it.

The Alexandra (Newport) Dock.—Ninety thousand cubic yards of this work have been completed, and the material used in raising the adjoining ground to the required level of the quays, leaving to complete the dock and entrance to the river, about 360,000 cubic yards, the greater portion of which is required for backing up the walls to their full height. The dock walls for their total length of 3,375ft. are built up to an average height of 15ft. above the level of the bottom of the dock, being nearly one half of the whole masonry, and throughout they have been founded on a bed of hard concreted gravel. The whole of the foundations of the lock, including the floors, cells, inverted arches, and recess walls, which embrace all the massive portions of the masonry, are nearly completed to the level of the springing of the inverts, and the whole rests throughout on an excellent foundation. There remain to complete this work only the side wing and recess walls to the coping level.

BUILDING NEWS SKETCH BOOK.

THE prizes offered by us in the BUILDING NEWS of June 18, 1869, have been awarded by the votes of the competitors as follows :—

1st prize of £10 10s., to Mr. H. A Gribble, for his sketch No. 17, "Westminster Abbey, North Transept," Feb. 4th, 1870.

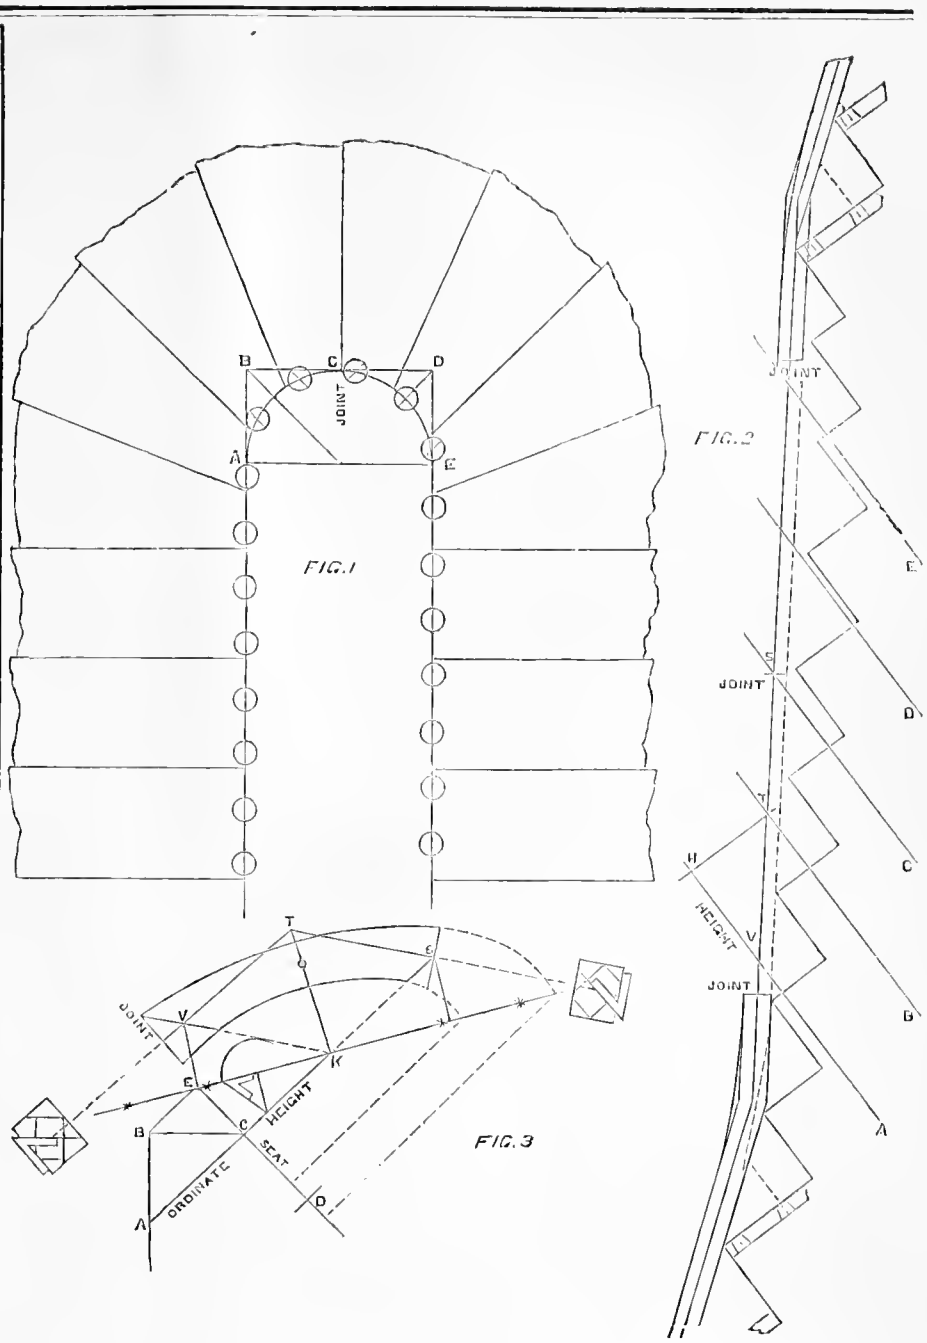
2nd prize of £7 7s., to Mr. Thomas Cox, for his sketch, No. 26, "Peterborough Cathedral," April 29th, 1870.

3rd prize of £5 5s., to Mr. T. Lennox Watson, for his sketch, No. 3, "Melrose Abbey, South Transept," Sep. 17th, 1869.

Without disclosing the secrets of the ballot, we may just say that Mr. Gribble has taken the first prize by an overwhelming majority of votes. Next to him on the list stands Mr. T. C. Wilberfoss, closely followed by Mr. Deshow; Messrs. Cox, Drinkwater, Ladds, Greensted, Langham, Grant, and Watson, possessing equally the smallest number of votes. The second prize is more closely contested, being won by Mr. Cox by a narrow majority compared with that of Mr. Gribble. Messrs. Wilberfoss, Deshow and Gribble, tread very closely on his heels. Mr. Watson and Mr. Grant come next; and Messrs. Hicks, Parker, Greensted, Bingley and Garratt follow at the bottom of the poll. The third prize is even still more narrowly won by Mr. Watson, Mr. Gribble very nearly being successful in carrying it off for another of his sketches (No. 8, Plympton S. Mary, Nov. 5th, 1869). Next follow Messrs. Drinkwater, Cox, Langham, Deshow, and the anonymous contributor of sketch 45 (Dunblane Cathedral, Oct. 14th, 1870), the lowest position of all being equally shared by Messrs. Ladds, J. Smith, Wilberfoss, Bethell, Dobson, Stevenson, Smales, and the contributor of sketch No. 9, whose name we do not know, and whose monogram is undecipherable.

THE INSTITUTE.

SOMEWHAT contrary to our expectations, the President of the Institute has had pretty much his own way as far as the Secretaryships are concerned. Possibly the new arrangement may be found, on trial, to work well. If so, all we can say is, that it might have been obtained at less cost. A question affecting the constitution of the society, and involving the destruction of two officers—either of whom has done more than Mr. Wyatt for the Institute—should at least have been submitted to the consideration of Council before it was launched at a general meeting of the members. Common courtesy towards his brother officers should have suggested such an ordinary course on the part of the President. Had it been first discussed in Council, and the probable advantages of the suggested new arrangement set forth, both Mr. Donaldson and Mr. Seddon, being reasonable men, and having the interests of the Institute at heart, would no doubt have cheerfully acquiesced in the change. But the President, either in his impatience to effect reforms, or fearing that he should not succeed in a Council meeting, precipitated matters as indicated in our first article last week. One of the immediate results was that Mr. Donaldson, an Hon. Sec. and ex-President, feeling that an undeserved slight had been cast upon him, resigned his office and Fellowship, and we are surprised that Mr. Seddon did not follow his example. We think that any four out of five high-spirited gentlemen would have acted as Mr. Donaldson has done. Any one who knows anything of Mr. Donaldson's connection with the Institute must know how deeply he was interested in its prosperity; the same might be said, in a modified degree, of Mr. Seddon. Had these gentlemen neglected the duties they undertook to perform, or were they mere cyphers, the President would scarcely be justified in his impatient proceedings. These proceedings have already produced bitter fruit. One Hon. Sec. has terminated his connection with the Society, and the other Hon. Sec., though he felt himself affronted, has curbed his feelings and condoned the offence. Let us hope, for the sake of the future peaceful working of the Institute, that the recent action of the President may not be regarded as a precedent. We do not so much object to the matter of the new arrangement as to manner of bringing it about.



NEW ELEMENTS OF HAND-RAILING.—PLATE XXV.

NEW ELEMENTS OF HAND-RAILING.*

(*Continued from page* 180.)

PLATE 25.—CONSTRUCTION OF SEMICIRCULAR STAIRS HAVING EIGHT WINDERS.

FIGURE 1 shows ground plan. Circle, or centre line of rail struck with a radius of eight inches. Narrow end of winders equal to a half square step.

Enclose circle with tangents A, B, C, D, E. These having cut the winders, give a direction to unfold them, measuring on tangent lines, and not on the circle.

Fig. 2 shows tangents and winders spread out. Letters along the margin correspond with those on plan. Adopt the same method as that for laying out a string. The object being to find pitch and height of wreath over winders. Also, of lower and upper ramps.

Let square steps stand in same position as those on plan. Have lower side of rail rest on corners of square steps.

Set off half its thickness. This gives direction to draw pitch, cutting through S, T, V. Being a straight line makes the pitches of wreath equal, and construction of mould simple.

The lower and upper part of wreath are equal heights. Centre joint is at S. Then H V shows half the height between V and S.

Fig. 3 exhibits construction of mould. Commence by making two sides of a square. Let A A B C equal corresponding letters above. Join A C extended. This is ordinate; being the diagonal of a square. Draw from B parallel with ordinate. Make seat square with it. Let C K, the height, equal that of H V on the right. Join E K extended. This is pitch and major axis.

To find points for striking curves:—Let D C equal C B. Set off on each side of D half width of rail. Square up to cut the pitch.

The most practical way is:—Have a piece of board suitable for mould. Lay it on, and mark E K. Let distance on right equal E K. Square over lines. This done, run a gauge, say an inch from the edge. Then let E V and that of S, equal E B. Make K T equal C A. Join

* This series of articles is a reproduction of ROBERT RIDDELL's work on the subject, published in Philadelphia, and by Trübner and Co., London.

S T and T V extended. These are tangents on mould ; and to be correct, must equal pitches on the right.

Next, let K O equal B C. Then set off on each side of O half the width of rail. All is now ready to sweep the mould with a string.

Pitches being equal, one bevel answers for joints, as the application shows.

METROPOLITAN IMPROVEMENTS.

Battersea.—The Metropolitan Board of Works has approved of Messrs. Beeston & Co.'s plan for the formation of three roads on the Parkfield Estate, Battersea, in continuation of roads known as Grayshott-road, Armfield-road, and Acanthus-road, upon condition that the existing barriers in Grayshott and Acanthus roads be removed, and that no other barriers to the traffic be erected on the estate. The Board has also decided to contribute one-half of the cost of an improvement proposed to be carried out by the Wandsworth District Board by the widening of a portion of Park-road, Battersea, at an estimated cost of £350, such contribution not to exceed the sum of £175.

Bermondsey.—At the last meeting of the Metropolitan Board of Works it was decided, on the recommendation of the Works and General Purposes Committee, that the Board should contribute one half of the cost of improving the thoroughfare at Nutkin's Corner, Bermondsey-wall, estimated by the Vestry at £870, exclusive of professional charges, such contribution not to exceed the sum of £435, and to be paid to the Vestry on a certificate by the architect to the Board of the completion of the work, and that the Board should contribute one half of the cost of an improvement proposed to be carried out in Blue Anchor-lane, at a cost of £130, exclusive of professional charges, such contribution not to exceed the sum of £65.

Shoreditch.—A Bill has been read a second time in Parliament enabling the Metropolitan Board of Works to widen High-street, Shoreditch. The street is to be widened on the west side thereof, commencing at the house No. 163 and terminating at Old-street-road. The Act stipulates that the Board shall, not less than eight weeks before they take in any parish fifteen houses or more occupied either wholly or partially by persons belonging to the labouring classes as tenants or lodgers, make known the same by placards, hand-bills, or other general notice placed in public view upon or within a reasonable distance from such houses, and the Board shall not take any such houses until they shall have obtained the certificate of a justice that it has been proved to his satistaction that the Board have made known their intention to take the same in the manner required. The Board is empowered, for the purposes of the Act, to borrow such money as they may from time to time require, not exceeding on the whole £150,000, and all the provisions of the Metropolitan Board of Works (Loans) Act, 1869 (except the limitation of amount in section 38 of the Act), shall extend and apply to such borrowing.

THE BRITISH TOWN AND FORT ON CAER SEION.

At the monthly meeting of the Archæological section of the Birmingham and Midland Institute, held on Thursday week, Mr. George Jabet read a paper on "The British Town and Fort on Caer Seion." The lecturer entered into a minute description of the situation of the town and fort on the hill which overlooks the Conway Bay, and also made some remarks upon points of interest in the surrounding country. The town and fort were on the hill on the left bank of the River Conway, which was the chief line of defence to the Welsh, although it was but a small river. Caer Seion was never occupied by the Romans, and consequently it remained unaltered, and furnished them with a specimen of an ancient British fortification and town. The lecturer, with the aid of some diagrams, gave a description of the remains as he saw them when he visited the locality, and stated the conclusions he had arrived at from the position of the mounds, the circles of stones, &c. In the course of his observations he explained that the modern meaning of the word town was not applicable in this case. In its true and etymological sense, however, it could be correctly used. In this sense it meant an inclosure, and there appeared to have been such an inclosure in this instance, as well as a series of forts which overlooked the town on the east and the west. Upon investigating the site it was evident that the huts were placed on the side of the hill which was easiest of access and most liable to surprise, and at points from which the advance of the enemy could be easily descried. In addition to the main body of the huts being placed on the most exposed side of the hill, there were two huts which were situated in more advanced positions, and which might be described as the abodes of those whose special duty it was to announce the approach of any hostile force. The hut of the chief, however, was placed in the part which was least dangerous, and this was a wise arrangement, because if the chief were taken or killed by surprise, it was probable the town and fort would also be taken. Cæsar admitted that the British showed no little skill in the arrangement of their camps. As to when the town and fort were first constructed it was impossible to say. It was not improbable that the hills of Britain were fortified with parallel entrenchments even before the Celtic tribes landed on its shores. The Celts on their arrival might only have conquered and occupied these strategical points, just as civilised powers in the present day took and occupied neighbours' territory under the name of material guarantee. Long before, perhaps thousands of years before the Celtic tribes—certainly before the Cymri—set foot in Britain, the country was inhabited by some tribes which about the same period occupied the greater part of Europe.

THE ALBERT MEMORIAL AND THE ALBERT HALL.

Our contemporary the *Examiner* hastens to congratulate the Chief Commissioner of Works, or whoever may claim the credit, "on the decisive step just taken to ensure a critical public's appreciation of the group formed by the memorial to the late Prince Consort, with its accessories, and the round-house nearly completed in front of it. Until the last few days a careless observer might possibly have failed to note the daring defiance of all rules of beauty and fitness by which two styles of architecture, hopelessly irreconcilable and perfect in their antagonism, have been brought into close proximity. But by an ingenious deflection of the broad walk which stretches across Kensington Gardens from the church at Lancaster Gate to the iron gates on the south of the Gardens, the visitor is now conducted at once to the Memorial, and all danger of the artists' skill in association and juxtaposition being overlooked is removed. This placing of the Gothic structure, the style of which is associated in our minds with grave and solemn contemplation, in conspicuous relief against the squat rotundity and Franconish aspect of the music-hall, or whatever other name it may rejoice in, would be amusing in its absurdity if it did not furnish another melancholy reason for believing that it is utterly impossible for us to achieve, or even conceive, anything like architectural propriety; and to make matters worse, the newly-opened walk leads the spectator up to the Memorial in a false line, as it were. The apex of that building ought, to the eyes of anyone approaching it, to coincide with the centre of the cupola of the hall. But it does not, and the effect, besides making the observer feel as if he were labouring under an obliquity of vision, is to give the monument the appearance of being out of the perpendicular: unless, indeed, it should unfortunately turn out that the Memorial tower possesses inherently a Pisan propensity to lean. When the obelisk was erected on the Place de la Concorde, though that erection was criticised at the time as injudicious, care was at least taken that the column should exactly bisect the Arc de Triomphe as the two objects were viewed from the Tuileries."

Portland Breakwater.—On Saturday week the operations connected with the construction of the Portland Breakwater were brought to a close by the depositing of the last stone, without the slightest display or ostentation, Mr. Coode, the engineer-in-chief, being present at the time. The gales of the last five or six months, many of which have been unusually severe, have not done the slightest damage to the work. It may, therefore, not only be regarded as finished, but safe from injury.

ARCHITECTURAL ASSOCIATION.

At the usual fortnightly meeting of this Association on Friday evening last, the President, Mr. Thomas Henry Watson, occupied the chair, and the following gentlemen were elected members :—Messrs Henry Vacher, Henry Crisp, and F. Wooding.

Mr. G. H. Birch was to have read a paper "On Christian Symbolism" ; but owing to illness, he had been unable to prepare one. In his stead therefore,

Mr. W. Paris, an architect well known for his works in India, read a paper

ON THE PUBLIC WORKS DEPARTMENT OF INDIA,

of which the following is an abstract :—

Mr. Paris commenced by quoting the old maxim —"A man cannot be Jack of all Trades" ; of which he said the Public Works Department of India afforded an apt illustration. The Public Works Department is a very large and important branch of the Indian Government, and it includes a great number of different departments, such as those of irrigation, railways, harbour, defences, architecture and the fine arts, &c. The appointments which Mr. Paris held were such, he said, as to enable him to realise most thoroughly the the utter fallacy of the Architectural Department as at present constituded in India. Prior to 1863, the office of Architect to Government, or as he he was then designated, "Civil Architect," was held by an officer of the Royal Engineers. The appointment was usually given to a senior officer, as in those days it was one of the highest paid sinecures of the service. In 1864, Government instituted an Architectural Department, and in due course, an Architect to Government was appointed both in Calcutta and Bombay. During Mr. Paris's tenure of office, he had great opportunites of tracing the source of the evil of Public Works Department architecture. When he first went to Bombay, the T-square was quite unknown, and it was only after a considerable time that the Royal Engineers and their assistants took kindly to its use. As Architect to Government, it was his privelege to receive all designs from those about to build on the land purchased from Government; and after duly criticising them it was his duty to forward them to the Government for final approval. The designs in most instances were ludicrous in the extreme. Mr. Paris narrated the following, as giving a fair illustration of a Bombay architect, such as Government is pleased to encourage in the nineteenth century. A Parsee (who signed himself "Architect and Surveyor") was requested by a native of considerable fortune to design him a house for one of his plots of land on the Esplanade. The Parsee readily complied, and prepared his design, which in due course he submitted to Mr. Paris. The design, however, was so bad, and showed such an utter ignorance of architecture (it was supposed to be Palladian) that Mr. Paris was induced to ask the Parsee what training he had received as an architect. "Oh," he remarked, "I have 'Gwilt's Encyclopædia,' and two or three other books from which I copy, but I never had any instruction." This was no solitary instance, and it was not to be wondered at that the buildings throughout India are a disgrace to the British Government, and unworthy of the name of architecture. The Government selects its architects from the Royal Engineers, Civil Engineers, and infantry and cavalry officers, and Padies, and at the present time the only architect by profession in the Governmental service that Mr. Paris knew of is Mr. Molecey, his fellow-pupil, and he is an assistant to a Colonel of the Royal Engineers at Bombay. In the benighted Presidency of Madras, as it is called, they have a quasi-architect to Government, but his title as such is suppressed altogether, and he is called an "Executive Engineer." In private life he enjoys the title and reputation of "Architect to Government," and he does the work appertaining to that appointment. It was simply from the fact of his title being kept *sub rosa* that he escaped the wholesale clearance that was made in the Architectural Department in January of last year. The officer referred to is a civil engineer by profession, and not an architect. In India, any man "who has a taste that way" (as is the expression used by the Indian Government officials), be he ever so ignorant of architecture, is sure to be singled out as a man of rare talent, and possibly called upon to prepare details of the design of some well-known architect at home, and the misfortune is that those holding the highest Government appointments are, as a rule, so ignorant of art and architecture that they cannot detect

the difference between an inferior and a meritorious design. The Government has an extraordinary idea that when once a small-scale design is prepared the architect's duties cease, and it is presumed that the officer who carries it out must of necessity be perfectly competent to work out the full-sized details, and hence one never had any particular satisfaction in preparing a design. It was truly distressing to watch the progress of Government buildings, as in all cases (except when models were prepared at the School of Art) the detail was simply the ignorant rubbish and insipid attempts that would naturally result from natives being employed upon it. Hindus and Parsees are engaged in designing Gothic caps and every other kind of detail. Mr. Paris quoted one instance where a Hindu was called upon to design a reredos for a church, and not only did he do so, but he actually modelled its ornament. The result might be imagined. One need not be surprised, therefore at the specimens of the Public Works Department in every station and cantonment of India, when, even in a highly-civilized city like Bombay, so much encouragement was given to the non-initiated. Of the old Public Works Department architecture at Bombay, the Cathedral, the Townhall, the Jamsetjee Hospital, &c., are beyond criticism, as they were built at a time when architecture was at a very low ebb, even in England; but now that architecture is an acknowledged profession, and that there is a School of Art in Bombay, it is a sad reflection upon Government that they should tolerate so anomalous a state of things. Sir Bartle Frere did much during his Governorship to encourage art and architecture, and Mr. Paris expressed his indebtedness to him for many acts of kindness and sympathy during his Indian career. It was during Sir Bartle's tenure of office that the School of Art was established, and he it was who was most instrumental in introducing architecture into the Government service; and Mr. Paris was of opinion that had Sir Bartle remained in office the Architectural Department would not have been a victim to the retrenchments which were called for by the Supreme Government at the beginning of last year. In proceeding to give his impressions of architecture "up country," Mr. Paris said that in every station and cantonment that he visited throughout all parts of India he found the inevitable "P. W. D." stamped on every church, hospital, barrack, memorial, &c. Nowhere out of Bombay (save a few exceptions in Calcutta) did he meet with a single building which was not an abomination. There were, however, degrees of badness; but in no case did he meet with a successful design or good details. At Umballah is perhaps the only church worthy of mention. It is a specimen of the Decorated period of English work, and at a distance it might be mistaken for a good thing, but on close inspection it is found to bebuilt of stucco, and the details are (as usual) carried out by ignorant hands, although there are decided evidences that an architect must have designed the building originally, the proportions and massing of the whole being unquestionably good. At Delhi is a very fair attempt at architecture in the building for the Government Museum; and it may fairly be concluded that an architect must have been concerned in its design. Mr. Paris thought it was greatly to be regretted that more encouragement was not given to the Hindus and Mahommedans to follow up their own peculiar styles of architecture, for it is too painfully evident that in domestic architecture they are losing all traces of their indigenous art, and in its place they were engaged daily in erecting buildings of a bastardised type of the very worst description of nondescript Classic.

Having read some extracts from Indian journals, showing the necessity for an improvement in matters architectural on that continent, Mr. Paris proceeded to give a sketch of the rise and progress of Indian architecture. The very earliest architectural history in India commenced with Sakya Muni (or Buddha), who died 543 B.C. Buddhism flourished for about a thousand years, when it gradually faded into the style contemporaneously elaborated by the Jains and Hindus, and dying out with the religion that gave birth to it. Next came the Dravidian tribes, who crossed the lower Indus into Guzerat, and who now occupy the whole (or nearly so) of the Madras Presidency, and are one of the greatest building races in the world. The next immigration commenced a century or two before the Christian era. They came across the lower Indus, occupied Guzerat and Rajpootana, and eventually extended to Mysore on the one hand and to Agra and Delhi on the north. The fourth great immigration was that of the Mahommedans, from the eleventh to the thirteenth and fourteenth centuries. They came across the upper Indus, and eventually spread down as far as Mysore. The earliest features of Buddhist art are topes, which consist of detached pillars, towers, and tumuli, all of a sacred or monumental character. The earliest specimens of topes consisted of single pillars (called lâts). The largest and most interesting tope is that of Sanchi, in Central India, of which some interesting casts may now be seen in the South Kensington Museum. The Buddhists did not build their temples and monasteries, but cut them out of the solid rock. The rock-cut temples and monasteries (or caves, as they are usually called) of Karli, between Bombay and Poonah, are the largest and most complete discovered in India, and were excavated at a time when the style was in its greatest purity. The exact date of their excavation is not precisely ascertained, but Mr. Fergusson ascribes it to the era of Salivahana (A. D. 78). Sad indifference is shown by Government for the preservation of these ancient and most interesting relics of by-gone ages. At the end of the cave, and in about the same relative position as that occupied by an altar in a Christian church, is placed the shrine—in this instance a plain dome slightly stilted on a circular drum. This is now covered with the cheapest description of bed-room wall-paper; and again, on either side of the entrance of the exterior façade are colossal sculptures of Hindoo mythology; these have all been painted a very brilliant yellow, and the features of the faces picked out in red and black, according to the caprice of the artist. All this has been done since 1864. The caves at Ellora, Kenneri, and Elephanta are also subject to similarly infamous treatment. It is strange to observe in caves of this class in India the reproduction of the still earlier wooden architecture into the lithic or stone excavations of the more modern ones. After dwelling at some length on the characteristics of these caves, and giving a slight sketch of the habits of the Buddhist monks or priests, Mr. Paris proceeded to speak of Jaina architecture. The religion of the Jains, he said, rose to importance only on the decline of Buddhism, which in many respects it resembles. Their temples are very costly and beautiful, as a rule, and their detail is full of the most interesting matter. Mysore and Dhauvai boast of a great number of Jain temples. The lotus of India is the prince of aquatic vegetables, and in Hindu mythology it is the emblem of female beauty. Brahma, it is said, sprang out of a lotus from the navel of Vishnu (the preserver); and throughout the Hindu ornamentation the lotus is the general characteristic feature. Jewellery is greatly introduced as a type of decoration. There is a marked resemblance in the conventional form of the lotus and the egg-and-tongue moulding of the Romans. Mysore and Dhauvai boast of a great number of Jain temples. The Jains, like their predecessors, the Buddhists, were great tower builders. At Chittore is a remarkable specimen built by Khumbo Rana. Mr. Paris next proceeded to give a hurried sketch of the architecture of India from the time of the first invasion by the Mahommedan tribes. In the course of his remarks under this head, he described the special characteristics of Ahmedabad and its architecture. Ahmedabad, in its most prosperous times, contained two millions of inhabitants, and its circumference was more than thirty miles. Of the numerous buildings in and about Ahmedabad, it is impossible in a slight sketch to give any thing more than a few remarks on this most wonderful of ruined cities. It was the singular fortune of the Mahommedans to find themselves among a people (*i.e.*, the Hindus) their equals in conception, their superiors in execution, and whose tastes had been refined by centuries of cultivation. While moulding them, they were moulded by them; and although insisting on the bold features of their own minaret and pointed arch, they were fain to borrow the pillared hall, the delicate traceries and rich surface ornament of their despised and prostrate foes. Hence, the architecture of Ahmedabad is imbued with a great deal of the severity of the Moslem builders, with an admixture of Jain delicacy and refinement of detail. It was a practice with the great and wealthy Mahommedans to build their own tombs during their life-time; and from that fact we find the tombs are of great costliness, and are no doubt infinitely superior to what they would have been had they been monuments erected after death. The mosques of Ahmedabad have a marked resemblance to each other in their general plan and design. On plan they consist of a court-yard surrounded on three sides by colonnades, the fourth being occupied by the mosque itself. The minarets of these mosques are attached to the central compartment, flanking each side of the principal entrance. Perhaps the most charming features of detail in these mosques are the pierced designs which fill the square window openings. It is contrary to the Mahommedan faith that the human form or animal life of any description should be introduced into the ornamentation of their buildings. The tanks at Sirkhy and Kankria, and the aqueducts and wells in the neighbourhood of Ahmedabad, prove that the Mahommedans were not only great architects in those days, but great engineers also. Their works were carried out on the most extensive scale, and the workmanship of the masonry is faultless. It is very sad, though, to see all these glorious remains of the past fast disappearing, but is nevertheless a fact that hundreds of miles of Government roads in India are macadamised with the *debris* and ruins of old Ahmedabad and other places of antiquity. Whilst at Sirkhy Mr. Paris found that the Government had undertaken some repairs to one of the palaces on the edge of the tank, and out of curiosity he examined the restored work, which was carried out in utter disregard of the feeling of the old work. These repairs were carried out under the instructions and superintendence of a lieutenant of the artillery, thus affording another instance of the anomalous system in the Public Works Department of making soldiers archæologists instead of keeping them steadily at work at their own peculiar profession.

A short discussion ensued, and the thanks of the Association having been unanimously tendered to Mr. Paris for his paper, the meeting terminated.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT the special general meeting on Monday evening last, the President, Mr. Thomas H. Wyatt, in the chair, the discussion as to the office of secretary to the Institute (referred to in our last impression) was continued. An amendment was proposed to the effect that the question should stand adjourned for the present. But the amendment having been put to the vote was lost. After which it was resolved—"That there be two secretaries of the Institute elected annually, one of whom shall be paid such salary as the Council may from time to time determine, and that the word 'assistant' be omitted from Section VIII., in the bye-laws."

Attention having been called to Professor Donaldson's proposed resignation as Honorary Secretary for Foreign Correspondence, and retirement from membership, it was unanimously resolved "That this meeting has received with great regret the resignation of the late Honorary Secretary for Foreign Correspondence, and with still greater regret the announcement of his proposed retirement from the Fellowship of the Institute. It trusts that he may be induced to reconsider that proposal, and that the Institute may long retain the affectionate sympathy and active co-operation of its well-known and greatly respected ex-President, Professor Donaldson."

The next ordinary general meeting will be held on Monday evening next, when the members will proceed to ballot for J. B. Mitchell Withers, of Sheffield, as Fellow, and to elect examiners and moderators for the Voluntary Architectural Examination of 1871. The following paper will then be read: "On the Construction of Theatres," by E. Salomons, Fellow. After which a special general meeting, of Members only, will be held, to consider a proposed scheme for an annual conference of architects, to be held at the Institute.

THE WELLINGTON MONUMENT IN S. PAUL'S.

THE Wellington Monument is one of those delightful little muddles which make us all so proud of British art and its connections with British officialism. Copies of further correspondence between Mr. Penrose and Mr. A. Stevens with different Goverment departments have just been published for the benefit of the House of Commons (and the Government

printers), in continuation of a former issue. Mr. Stevens states that he is prepared to complete the monument without the equestrian figure by March, 1872, for £4,000. The First Commissioner of Public Works has taken possession of the model and materials of the monument, inclosing them by a hoarding in Mr. Stevens's studio, kindly offering him rent at the rate of 10s. per week for the space inclosed. Mr. Stevens can hardly be blamed for objecting to having his studio thus parcelled out like a building plot at a nominal ground-rent, especially when it is rendered unavailable for other purposes. The whole tone of the correspondence is, as might be expected from anything with which Mr. Ayrton had to do, most amiable and friendly.

ART THEORIES.

MR. F. W. MOODY, in a letter in the *Society of Arts Journal* on Dr. Dresser's Paper on Art, says:—What would the medical world say, if the College of Physicians lent their rooms and the *prestige* of their name to some enthusiastic herb doctor, who, entirely ignorant of anatomy or chemistry, proceeded to prove to the students that his herbs were the only true antidotes for all the diseases of the flesh? Would not the medical world blame the College of Physicians rather than the poor herbalist? And has not the art world some right to expect that such an institution as that of the Society of Arts should take care that the lectures delivered in their hall are not the crude theories of half-developed artists, but sound instruction from experienced and learned men?

And now, sir, would you allow me to say a word about art theories, for I, too, have a theory about art, and my theory is, that theories of art are the curse of the age. We have now had more than thirty years of them, and I am convinced that if half that time had been spent in work, we should long ago have been in the full swing of a great era of art. A man must have used his wits to very little purpose if he has not long ago perceived that, with very few exceptions, the theories of the day are either the sophistries spun by the weak, with the vain attempt to keep the strong within the narrow limits of their own capacities, or they are the dogmas of critics, by which they can easily condemn those they do not understand. They are cheap patent Procrusteau bedsteads, on which the critic in imagination lops off the limbs of the giants he has tied to them; but, if we trace these theories to their source, we invariably find nothing more than the "*I*." "*I* say so."

A theory, like a mummy, is enshrined in many cases. The outside is very gorgeous; it is written over with the names of the gods, and with symbols and mysteries; but, when you have taken off case after case, and roll after roll, each more tedious and intricate than the rest, you come at last to a poor, little, black, wizen monkey of a man.

I know only one use of art theories, and that is a very small one. If an artist talks to me on such subjects for a quarter of an hour, I know what he can do quite as well as if I saw his work. And I have had many a talk with theorists of all sorts, and I always say to my friend, "That is a very pretty theory of yours, and now will you come for a walk with me into Kensington Museum, and into the library there, and we will fit it on?" and I invariably find that in half an hour we have condemned most of the great men that ever lived. I am bound to confess that this result hardly ever weakens the confidence of the true theorist. If Raphael differs from him, so much the worse for Raphael. But I say to my friend, "No doubt my taste is depraved. I attribute that to the fact that I have been born and bred in that obscure quarter of the globe called Europe, and so I admire works which your Oriental tastes condemn. I am a plain man and no philosopher, and these things which you have proved to be on wrong principles seem to me the great works of great men, who probably knew their business quite as well, perhaps even been better, than a novice, or even an amateur."

The only cure for art theories (but that is a certain one) is art power. If the theorist is lucky enough to attain to this, he quietly drops his theories, for, if he is a wise man, he knows he has made a fool of himself, and he sets honestly to work to learn his business and redeem, if possible, the time he has wasted in nonsense. It will be a happy day for art when its votaries work instead of talk, and are no longer disturbed by the idle theories of the ignorant.

THE LONGEST TUNNEL IN ENGLAND.

THE London and North-Western Railway, from Liverpool and Manchester to Huddersfield and the North, passes through a range of hills separating Marsden on the Yorkshire side and Diggle on the Lancashire side, the range bearing the name of Stand Edge, and it has now three tunnels running through it—one a canal tunnel, and the other two for the purposes of the railway. The first-named was commenced in 1794 and completed in 1811; length, 5,451 yards, or three miles and 171 yards; cost, £123,803; and the loss of life during its progress was serious. The first of the two railway tunnels was made by Mr. T. Nicholson, contractor for the Woodhead Tunnel, which is shorter than the Stand Edge one by about 40 yards, Stand Edge being three miles and 60 yards long. It was commenced in 1845 and completed in November 1848; the cost was £171,003 12s. 3½d.; of the approaches £30,695, making a total of £201,608., and the largest number of men employed on the undertaking was 1,953. Nine fatal accidents occurred in its construction. Messrs. Thomas Nelsen and Sons, of Carlisle, were the contractors for the new tunnel; the work was commenced in the middle of April, 1868, and was completed in the middle of October, 1870, or six months earlier than the time specified. Its exact length is 5,435 yards, one yard less than its twin tunnel; but the actual length constructed by the Messrs. Nelson is 5,297 2-3 yards, the difference arising from a short piece at each end having been made when the first railway tunnel was executed. The whole length is lined with red bricks, faced with blue Staffordshire bricks. The height of the tunnel inside the brickwork is 20ft., and the width 15ft. The total quantity of brickwork built is 52,156 cubic yards, the total number of bricks used being 16,831,149, the weight of which amounts to 68,000 tons; 6,271 tons of coal, 472 tons of coke, 2,421 tons of lime, 140 tons of cement were consumed; and of powder 1,744 casks, equal to 174,400lb.; fuzees, 35,853 coils, each 25ft., equal to 170 miles; candles, 8,745 dozen pounds, equal to 104,940lb.; oil, 6,416 gallons; and vast quantities of timber were used. The rubbish was conveyed away by means of tramways, which ran through passages under the railway, and was tipped into boats on the canal before mentioned. It was conveyed through "break-ups" or cross-headings, of which Messrs. Nelson constructed 21; but only 16 were used at one time. For the conveyance of the material used in the construction of the tunnels 25 boats and four steamboats were constantly plying, and an immense expense had to be incurred in erecting huts, providing business offices, and putting down costly plant for economizing labour. Only one life has been lost during the construction, but there have, of course, been plenty of accidents of a less serious nature. The work has been pronounced satisfactory in all respects, and the line is reported as being one of the smoothest portions of railway travelling in the kingdom. The line was opened about the middle of last month for regular traffic.

PARLIAMENTARY NOTES.

The Wellington Monument in St. Paul's Cathedral.—The Marquis of Lansdowne, on Friday, in the House of Lords, moved for the production of all further correspondence relative to the Wellington Monument that had passed between Mr. Peurose and Mr. Stevens with any department of her Majesty's Government up to the present time.—The Lord Chancellor put the motion, which was carried.—The Earl of Cadogan said that after the correspondence had been laid on the table of the house he should call attention to the subject. Lord Overstone was about to address their lordships, when Lord Chelmsford reminded his lordship that the motion was carried. Lord Cairns said some misunderstanding had arisen from the hasty manner in which the motion was put from the Woolsack. He had not the remotest conception what the motion was about. The Marquis of Lansdowne said the only explanation he could afford their lordships was that he was asked as a matter of form by the noble earl (Cadogan) to move for the production of the correspondence in order that the subject might be brought before the house. Lord Overstone said the history of this transaction was a very curious one, and it was necessary that public attention should be called to it without delay. When the House of Commons voted a sum of money for the erection of a monument to the late Duke of Wellington in St. Paul's Cathedral, he formed one of the committee who selected the designs. After that, the Government determined to change the site, and they chose another design. The sum voted had been spent, and all the country had got for its money was the fragment of a monument in St. Paul's Cathedral and certain other fragments now lying in the artist's studio. He had been informed that the Government had made an effort to enter into an arrangement whereby they would have greater control over the artist than they had at present, so as to be able to give an assurance to the country that the work would be speedily completed. He hoped that would be the case, but he was by no means confident of it.

Epping Forest.—Sir H. T. S. Ibbetson, on Monday, asked the Chancellor of the Exchequer whether he was aware that the timber in High Beach, a part of Epping Forest, was being marked previous to being cut down by private people; and if so, whether he was prepared to take any steps to restrain such action till the question as to the enclosure of Epping Forest had been decided.—The Chancellor of the Exchequer was sorry to say it was not in his power, even if he were willing, to take any step in the matter. The Government had had no property in the land of Epping Forest, but only forestral rights over it, and their rights had been extinguished.

The Wellington Monument.—Mr. Heygate on Tuesday asked the First Commissioner of Works what steps had been taken since November, 1870, to secure the completion of the Wellington Monument by some sculptor of established eminence.—Mr. Ayrton replied that the subject had been under the consideration of Government ever since November, 1870, to ascertain if any arrangement could be made in reference to it, but they had not as yet arrived at a final determination, but would do so in the course of a few days, when the papers would be laid on the table.

Building Intelligence.

CHURCHES AND CHAPELS.

Oxton.—The foundation-stone of a new Wesleyan chapel was laid last week, at the corner of Palm-grove and Talbot-road, Oxton. The cost of the entire building, when completed, will be about £6,000. The edifice will be constructed of Yorkshire stone, with Stourton dressings. The first part of the building to be erected will accommodate 300 worshippers, but when entirely completed it will seat 600 or 700. The architect is Mr. C. O. Ellison, and the contractor for the work is Mr. Alexander Bleakley, of Birkenhead.

Rugby.—On Monday week last the foundation-stone of a new tower at the west end of the Roman Catholic church was laid. This tower will form the western entrance, and will be surmounted by a spire. It will cost between £4,000 and £5,000, and is being built by Messrs. Parnell & Son, of Rugby.

S. George's, Bloomsbury.—The spire of S. George's, Bloomsbury, is now undergoing repairs. The figures at the base of the pyramid were so dilapidated as to endanger the limbs and lives of those whose business took them through the church-yard below. Is this another instance of the unsuitability of Bath stone in a London atmosphere?

BUILDINGS.

New Fever Hospital for Bolton.—At a special meeting of the Bolton Board of Guardians last week, plans for a new fever hospital, with ward for small-pox cases, were adopted. The plans have been prepared by Mr. George Woodhouse, architect, Bolton. The building, which will be erected near to the workhouse, at Farnworth, will accommodate 44 patients, and the cost is estimated at about £5,000.

Thelwall Schools, near Warrington.—These buildings which have now been commenced (the contract having been let to Messrs. John Collin & Son, of Warrington), will stand upon a portion of the Hall grounds, which has been given for the purpose by James Nicholson, Esq., of Thelwall Hall. The contract also includes the alteration of the present school, which, with additions, will become the school-house or residence for master. This building, together with the land it stands upon, and small garden, is the gift of Henry Stanton, Esq., of Thelwall. The whole will be carried out from the designs and under the superintendence of Mr. William Owen, architect, Warrington.

New Sunday Schoolrooms, in connection wi Mr. Spurgeon's Tabernacle, are about to be erect at a cost of about £2,500.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

To Our Readers.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office not later than 5 p.m on Thursday.

Received.—J. H., E. H., R. T. W., A. B., F. N., T. C., J. P. S., A. G. T., A. T. T., J. M.

Monumental.—Inadmissible as a query.

Tudor.—We can't say without seeing photo. and plan.

Hope Deferred.—We have been waiting for good sunlight.

G. T. C.—Your letter, though inoffensive enough, is irritating. You offer suggestions and give advice without the necessary ability to do either. You don't know what has appeared in the Building News, or you would not have advised us to give the competition designs for the New Law Courts. You don't know what is good architecture, or you would not recommend us to give meretricious illustrations in preference to unpretentious executed works, and you do not know the value of A. Durer's engravings, or you would not say they should have no place in an architectural journal. Every copy of the Building News, which contains a reproduced engraving of the great German master will, in years to come, fetch more than its published price. When you know more you will probably give less and better advice.

A Country Carpenter.—Thanks for the suggestion which had, however, been anticipated by us.

Correspondence.

THE INSTITUTE AND ITS PRESIDENT.

To the Editor of the Building News.

Sir,—I have no intention to question your right as the editor of a professional paper to criticise as severely as you please any act of mine in the quasi-public position I have the honour to hold as President of the Institute of British Architects, but I do protest against the mis-statements you have made in your leading article of last week.

You call my recent action with reference to the Secretaryship of the Institute a *coup-d'etat* ; and you state that I promised in my opening address of last November that "further due notice should be given of my intention to propose a change."

I gave no such promise. You then add, "No such notice was vouchsafed either to the Council or the Institute until on Monday evening he disclosed his plot." I do not know what you may consider "due notice," but the usual fortnight's notice was given of my intention to bring this subject forward, and I stated at the meeting of the Council that I should do so. The members have since had another week to consider this matter, and with what result you have, no doubt, heard.

You subsequently state my proposition to be "that the present paid 'Assistant Secretary' should be raised to the office of Chief Secretary, to have the sole control and management, under the Council, of the affairs of the Institute." I made no such proposition. I never contemplated that the Assistant Secretary should be Chief Secretary, or that he should have anything but his own immediate home duties to attend to.

You say, "An Honorary Secretary is supposed to have some policy." I presume that the same privilege may be extended to the President of a society, without his being thought "ambitious," "insidious," or "over active."

You conclude by stating that *coups-d'etat* are usually "condoned if successful." As more than two to one of the members present on Monday evening, having had three weeks to consider my proposition, and having, no doubt, met in the "calmer spirit" you desired, have sanctioned my "insidious design," I trust I may be supposed not to have entertained it "without some forethought."

As you have published Professor Donaldson's letter to me, which was not accurate in all its statements, I must request you to publish my reply to it, even though somewhat late in the day.—I am, &c., Thos. Henry Wyatt.

Copy.

77, Great Russell-street,
Thursday Evening, March 9, 1871.

My Dear Donaldson,—

On my return to town this evening I find your official letter of yesterday, placing unreservedly "your resignation in my hands" (as President of the Institute), "and requesting that your name may be withdrawn from the list of Fellows." I can only say that I receive this communication with much regret and I may add much surprise, for although you may mistrust the policy of the change I have suggested in the administration of the Secretary's Department in the Institute, and might even be disinclined to continue your valuable services as Honorary Secretary for Foreign Correspondence, I cannot understand why you should feel impelled to withdraw your name as a Fellow, and it is as difficult for me to comprehend how you can suppose for one instant that any "humiliating subordination" for yourself was ever contemplated by me, or by those who share my views, in desiring to *concentrate responsibility* in the *home* work of the Institute.

You should not suppose that because we exercise conscientiously our judgment as the best means of adding to the efficiency and *life* of our Institute that we are forgetful or unmindful of what you truly describe as "most earnest services and unswerving duty during six-and-thirty years." I believe they are universally acknowledged, and I believe it would be very generally gratifying that you should continue to act as our Secretary for Foreign Correspondence, an office that may be held in *perfect independence* of the Secretary who takes charge of the *home* duties, and therefore in no way "subordinate" to him. Such an arrangement works most effectively in the Institution of Civil Engineers, with which I have had the honour of being connected for many years, and have seen its successful results. There the name of the Honorary Secretary takes precedence of the paid Secretary, as I had anticipated yours would do in our case. The duties and responsibilities are distinct, and as you so clearly put it the other night, the labours consequent on the duties of Honorary Secretary for Foreign Correspondence are, I am confident, as much as should in reason devolve on one who renders *honorary services*.

Let me correct an error into which you have fallen with regard to my proposition to the Institute. I never for an instant proposed "that the present Assistant Secretary should be raised to the office of *Chief Secretary*, and should have the *sole control* and management (under the Council) of the affairs of the Institute." I do, however, wish that Mr. Eastlake, who *now practically* has the labour oar of our Institute, who edits our Transactions, prepares our Minutes, and who carries on the bulk of the correspondence, should have the whole responsibility and credit of the work he does, and should be spared the unnecessary labour and waste of time in constant reference to the Honorary Secretaries. I believe it will be for the interests of the Institute that the paid Secretary (and I know no one who could perform those duties more efficiently than Mr. Eastlake) should be independent of any other control than that of the Council, and feeling this strongly, I have thought it my duty to submit the question to the judgment of the whole body, even at the painful cost of appearing to differ from one for whom I have invariably had the greatest regard and respect. To the decision of the Members on this question I shall most cheerfully bow, and if your view should be upheld, will co-operate as cordially as ever under the existing "regime."

I remain, my dear Donaldson,
Yours very faithfully,
T. H. Wyatt, P.R.I.B.A.

T. L. Donaldson, Esq., &c., &c., &c.

LEICESTER MUNICIPAL BUILDINGS.

Sir,—You mention in your last that only twenty-seven designs have been sent in for the Birmingham Assize Courts. If I recollect rightly more than two hundred copies of the instructions were said to have been issued. If the Birmingham Corporation had been as wise (?) as their Leicester brethren, and had charged £1 for each copy of their instructions as a deposit, they might have realized by the forfeited pledges not only enough to cover the cost of printing and lithographing, but a sum sufficient to pay the second and third premiums as well. This, evidently, is the idea of the Leicester body. Whoever is simple enough to procure their instructions will no doubt find that *as the £1 deposits of the successful competitors are to merge into the premiums*, so the first premium (£200) is to merge into the commission. The others (£100 and £50) being already provided for in the manner I have suggested would, you may perceive, render the transaction a most inexpensive one to the promoters.—I am, &c., A. B. C.

BIRMINGHAM ASSIZE COURTS.

Sir,—If your Birmingham correspondent's surmise "that Classic will not be adopted" is based on a knowledge of the feeling of the Corporation, and of the existence of a foregone conclusion as to style, then competitors who may have prepared Classic designs will have much reason to complain, inasmuch as the Corporation, in their instructions, *pointedly* left the question of style an open one. If it is based merely on the fact that the architect "appointed to advise" is more particularly identified with the Gothic school, it seems not altogether complimentary to a gentleman who, under such circumstances, might be expected to take the broadest views.

The Corporation, I observe, do not bind themselves to adopt for execution any of the premiated designs. As they "reserve to themselves the right of ultimately deciding which set of plans shall be adopted," their feeling, if they have any, as regards style, should be the less allowed to influence the consideration of the adaptability and merits of the designs in the first instance.—I am, &c., Greek.

[We have no doubt that Mr. Waterhouse will be influenced in his adjudication by the "broadest views."—Ed.]

TIN-LINED PIPES.

Sir,—In your journal for February 3rd, a correspondent, referring to a paragraph quoted by you from the *Boston Journal of Chemistry*, remarks as follows :—

"It is a great pity that the paragraph has obtained currency in this country. I can only suppose it originated in malace, it being opposed to the plainest facts. Water does not corrode tin, nor is there any probability of galvanic action being set up."

The first mention of the subject in the *Journal of Chemistry* was in September, 1867, when the editor, Dr. J. R. Nichols, a chemist of large experience, said :—"After careful examination of this pipe, we hesitate to give it our approval. We fear it may prove more dangerous than pipes constructed wholly of lead." This attracted much attention, and persons interested in the manufacture of the pipe insinuated, as your correspondent has done, that it was malicious. In a longer article on the subject, published in July, 1868, Dr. Nichols says :—"At the time, we did not know the name of the inventor or manufacturer ; and we neither entertained nor expressed a doubt of the entire integrity of purpose of those parties. . . . The impression prevails that pure tin pipe is practically indestructible when placed in the ground for conveying water. This is certainly an error. We have had a section of tin pipe in our possession which *was corroded through and through, and yet it had been in use only six months*. This occurred in the city of Manchester, New Hampshire." With regard to the tin-lined pipe, he gives the following facts :—"A physician recently brought to us a section of tin-lined lead pipe, taken from the well of a patient suffering from lead poison, which perfectly illustrates the position here taken. In putting the pipe in place, it had been bent at right angles at a point near the water, and the plumber, in attaching the pump above, had allowed a portion of solder to drop through the pipe, lodging directly at the bend. *Speedy corrosion commenced at this point*, promoted by galvanic action. *The lining was perforated, and lead poisoning of a marked character resulted.*"

Of the fact of corrosion in these cases there can be no doubt, whether Dr. Nichols is right or wrong in asserting that the corrosion was "promoted by galvanic action." Recent experiments appear to show that the galvanic action in the case of lead and tin is very slight ; and, if so, it cannot materially accelerate the corrosive process. The important fact, however, is that *corrosion may take place*. Instances of the kind may be rare, but it is clear that they *do occur*. We do not understand that the makers of this pipe deny this. They tell us that some of the pipe first put into the market was imperfectly made, and the like. They admit, moreover, that when the pipes are joined in the ordinary way by soldering, a portion of the tin lining is fused and the lead laid bare for some *four inches* of its length. They claim that this exposed surface of lead will not corrode more rapidly than the same length of ordinary lead pipe ; but in the case of waters that act readily upon lead we do not wish to have even a small surface of that metal exposed to such action. The makers of the pipe have themselves

seen the force of this objection, and have now devised a means of connecting the pipes by screw joints, without solder. This is unquestionably an improvement, but whether it renders the pipe *perfectly* safe *in all cases* is by no means certain. The subject is still under discussion in this country, and the *Journal of Chemistry* will probably have something more to say about it.

W. J. Rolfe, Associate Editor of
Journal of Chemistry.

Boston, U.S,, Feb. 21.

SUNLIGHTS.

Sir,—Having used the sunlight for the combined purpose of lighting and ventilating in a large number of public buildings, I think I can supplement the information in your article by the result of my experience.

The first I used was at Bromley Town-hall, in 1865. I saw Messrs. Strode on the matter, and they recommended their mercurial regulator for the prevention of down draughts in the flue of the sunlight when not in use. I determined, however, upon a simpler expedient of my own invention, viz., to attach two plates of mica to the inner sides of the square vertical flue, or upcast shaft, to fall inwards and close on to a central bar at an angle of about 45°. The mica is so light that the least upward movement in the column of air raises the valves, and they are prevented opening more than 35° by a stop, otherwise they might have become set open. When the light is not in use they fall close of themselves, and any downward current keeps them tight; immediately the burners are lighted the ascending current of warm air opens the valves and readily escapes. I finished the top of the flue with one of Benham's wind guards.

The late Mr. Boyle was one day at my office, and speaking of the mica valves, he said I was infringing his patent, which consists in the use of mica dampers to chimney breast ventilators. We settled our difficulty by my paying him a royalty of 2s. 6d.

As Surveyor of Police, I had occasion to deal with the defective state of the ventilation of the Police-court in Great Marlborough-street, and I determined upon a sunlight. In this case I finished the top of the upcast shaft pyramidally, placing the mica dampers on the outside, like a series of Boyle's chimney-breast valves; at the same time I made improvements in the construction and means of fixing of the upcast shaft and wind-guard, so as to increase its ventilating powers. The sunlight is in daily use at Marlborough-street, and Mr. Knox, the magistrate, can speak of its efficacy, though from motives of economy, I did not enlarge the fresh air supply to the extent I considered desirable. The sunlight was manufactured and fixed complete by Mr. Freeman, of Vine-street, Piccadilly, the talc cone used being Strode's patent.

These improved sunlights have subsequently been fixed at several other police courts with equal results.

The defective state of ventilation in the county courts at Bloomsbury and Westminster was referred to me as Surveyor to the Treasury for County Courts. The arrangement in use provided for bringing in warmed air through large grated holes in the walls about 10ft. above the floor, and an inefficient appliance for withdrawing the fouled air at the floor level. The result was a superheated state of the upper portion of the court, and a very foul state of the general atmosphere, with attendant headache and cold feet for all those who had to remain long in the court. I closed the inlets of warm air at the high level and diverted an increased supply of fresh warmed air (availing myself of the old heating medium) and distributed it by inlet gratings at numerous points just above the floor level, so as to create a general movement of the lower stratum of air; I placed an improved sunlight—as at Marlborough-street—with great extracting power, in the lantern light; this is not lighted until the court is warmed, it then gives a gentle upward movement to the whole atmosphere, and even on the most crowded days is found perfectly successful.

The usher, standing near the bench, can control to a nicety the supply of fresh air and the velocity of the out-going current in the sun-burner.

The same principle has subsequently been introduced, under my direction, in several more of the metropolitan courts, and in numerous county courts and other buildings throughout this country; the sun-lights being manufactured and fixed in all cases by Mr. Freeman.

I may add that the enamelled metal basins frequently seen are very dangerous and unsatisfactory; their shape is such that they condense and throw down the heat on to the heads of those below to an incredible degree; the enamel frequently flies by the action of the heat; it soon gets discoloured and black; and from the opacity of the cone, throws the whole ceiling into shade. The patent cone of Strode's manufacture, which I always use, is entirely free from all these defects.

I am, &c.,
Thomas Charles Sorby.

27, Brunswick-square, W.C., March 14, 1871.

Intercommunication.

QUESTIONS.

[2160] CIVIL ENGINEERS.—Will some of my fellow readers of the Building News kindly inform me of a few particulars respecting the Institute of Civil Engineers? 1st. What benefit does it confer on its members, especially on those 300 miles from London? 2nd. Is there any branch establishment in the North of England, or would it be difficult to form a branch establishment at a place like Carlisle? 3rd. What are the terms, and is there any examination to pass? What is really the qualification of a civil engineer? The address of the secretary, and other information thankfully received by—Rusticus.

[2161] TIMBER.—Will any of your readers kindly inform me if deals from Gefle, Gothenburg, or Soderhamn are as strong and as durable for carpenters' work as what is termed best Baltic timber in specifications?—Would do Right.

[2162] ORIGINAL DESIGN OF ST. PAULS.—Could any of your readers inform me where a plan of this building is to be found?—F. L. P.

[2163] WATER CLOSETS.—Can any of your subscribers inform me from practical experience what class of water closets prove the most desirable as regards sanitary arrangements, simplicity, and durability for a large school, where constant use and rough usage are the average treatment? There would be required between six and twelve, all contiguous to one another, and clear of the main building.—An Old Subscriber.

[2164] CONSERVATIVE LAND AND BUILDING SOCIETY.—Required; the result of the recent appeal for a surveyor and assistant auctioneer to the above-mentioned.—S.

[2165] ARCHITECTURAL TRAVELLING SCHOLARSHIPS.—Where can I obtain information about the various architectural scholarships competed for in London? J. W. Woodsend.

REPLIES.
